SAMA7G5 Series

Up to 1-GHz Arm® Cortex®-A7, MIPI Camera, Dual Ethernet, Audio and Security

Introduction

The SAMA7G5 is a high-performance, ultra-low power Arm Cortex-A7 CPU-based embedded microprocessor (MPU) running up to 1 GHz, with support for multiple memories such as 16-bit DDR2, DDR3, DDR3L, LPDDR2, LPDDR3, octal/quad SPI and e.MMC Flash.

The SAMA7G5 integrates complete imaging and audio subsystems with 12-bit parallel and/or MIPI-CSI2 camera interfaces up to 8 Mpixels, up to four I^2S, one SPDIF transmitter and receiver and a 4-stereo channel audio sample rate converter.

The device also features a large number of connectivity options with Dual Ethernet (one Gigabit Ethernet and one 10/100 Ethernet), six CAN-FD and three high-speed USB and offers advanced security functions (secure boot, secure key storage, high-performance crypto accelerators for AES, SHA, RSA and ECC).

Features

- Arm Cortex-A7 Core
  - Arm TrustZone®
  - NEON multimedia architecture
  - Floating Point Unit
  - Embedded Trace module with instruction trace stream, including 16 Kbytes of CoreSight™ Embedded Trace buffer
  - 32 Kbytes of L1 data cache, 32 Kbytes of L1 instruction cache
  - 256 Kbytes of L2 cache
  - Up to 1 GHz operational frequency
  - Voltage and frequency scaling support
  - 64-bit generic timers
- Internal Memory Architecture
  - 128 Kbytes of internal SRAM and 5 Kbytes of secure backup RAM
  - 80 Kbytes of maskable ROM, embedding a secure boot loader (boot on QSPI NOR, SLC NAND, SD, e.MMC)
  - 96 Kbytes ROM for NAND Flash ECC tables
  - 40 Kbytes ROM for crypto-libraries (RSA, ECC, etc.)
  - 11 Kbytes of internal OTP
- External Memory Support
  - 16-bit high-bandwidth, double data rate multi-port dynamic RAM controller. Supports up to 16 Gbit 8-bank DDR2/DDR3/DDR3L/LPDDR2/LPDDR3 up to 533 MHz
  - 16-bit static memory controller, FPGA support with synchronous clock
  - 8-bit SLC and MLC NAND controller with up to 32-bit error correcting code
  - One 8-bit high-speed memory card host e.MMC 5.1 (HS400), SD3.0 SDR104 mode support
  - Two 4-bit high-speed memory card hosts e.MMC 4.51 (HS200), SD3.01 SDR104 mode support
  - One octal Serial Peripheral Interface running up to 200 MHz DDR

  - One quad Serial Peripheral Interface
- System
  - Power-on reset cells, reset controller, shutdown controller, watchdog and secure watchdog timers running on internal slow RC oscillator (32 kHz typical) and real-time clock running on slow crystal oscillator (32.768 kHz)
  - Two internal trimmed RC oscillators with typical values: 32 kHz and 12 MHz
  - Two crystal oscillators: 32.768 kHz and 20 to 50 MHz
  - Eight PLLs for core, system bus and peripherals, serial interfaces, DDR I/Os, pixel clock, audio, USB, MIPI CSI-2 and Ethernet
  - Two 32-channel DMA with per-channel security configuration
  - One 8-channel DMA dedicated to memory-to-memory transactions
  - Eight programmable clock output signals
- Power Considerations
  - Different power domains and power modes to reduce power consumption
  - Low-power consumption in Backup mode with 5 Kbytes of secure backup SRAM and DDR-SDRAM in Self-Refresh mode
  - Low-power with SRAM and register retention, wake-up from various events (USB, CAN, Ethernet WOL, FLEXCOMs), internal events (RTC, timer) and I/O activity
  - Embedded LDOs for MIPI CSI-2, analog and PLLs, to enable low-cost power management solutions
  - Optimum connection to Microchip MCP16501/2 PMICs to enter and exit various power modes of the application.
- Multimedia Peripherals
  - Audio
    - Two synchronous serial controllers, each with 16 channels of up to 32-bit TDM data
    - One inter-IC sound multi-channel controller with TDM256 support
    - Up to two 4-channel pulse density microphone controllers; support for eight microphones in parallel
    - One Sony/Philips digital interface transmitter and receiver
    - Audio sample rate converter including four stereo channels
  - Image
    - Image sensor controller, ITU-R BT. 601/656 supporting up to eight megapixels for still images and 60 fps in 720p mode, 8 bits, raw Bayer, YCbCr, monochrome, camera ISP
    - 2-lane MIPI CSI-2 (D-PHY) and 12-bit RGB interface support
- Peripherals
  - Two high-speed USB devices and three high-speed USB hosts sharing three on-chip transceivers
  - One 10/100/1000 Gigabit Ethernet MAC supporting RGMII, MII and RMII (GMAC0) and one 10/100 Ethernet MAC supporting MII and RMII (GMAC1) compliant with:
    - IEEE802.3az Energy-Efficient Ethernet
    - IEEE802.1AS Timestamping for Ethernet AVB support
    - IEEE802.1Qav Credit-based traffic shaping hardware support
    - IEEE1588 Precision Time Protocol
    - IEEE1588 Timestamp Unit (TSU) with TSU timer comparison signal triggering a timer counter and available on a PIO line
  - Six flexible data rate CAN-FD controllers with SRAM-based mailboxes with time- and event-triggered transmission
  - Twelve FLEXCOMs (USART, SPI and TWIHS)
  - Six 64-bit timers
  - Two three-channel 32-bit timer counters, with PWM generation
  - One four-channel 16-bit PWM controller
  - One 16-channel 12-bit analog-to-digital converter, up to 1 Msps
- Safety
  - Temperature and core voltage monitoring

- Zero-power power-on reset cells
- Main crystal monitor and clock failure detector with failsafe switchover to main RC oscillator
- 32 kHz crystal monitor and clock failure detector with failsafe switchover to internal 32 kHz RC oscillator
- Integrity check monitor based on SHA256
- Safety critical modules (WDT, RSTC, SHDWC, etc.) running on always-on slow RC oscillator
- Register write protection

- Security
  - TrustZone support
  - One Secure TrustZone watchdog timer running on RC oscillator, providing protection against TrustZone starvation
  - Temperature, voltage and frequency monitoring
  - Secure backup SRAM
    - 5 Kbytes scrambled with non-imprinting support powered with VBAT or VDDIN33:
      - 1 Kbyte non erasable on tamper detection
      - 4 Kbytes erasable on tamper detection
  - Four tamper pins for static or dynamic detection
    - Can be used as regular wake-up lines
  - 256-bit general purpose backup register, erasable on tamper detection
  - Programmable OTP with bits available for user purposes
  - Configurable JTAG security (full debug, non-secure-only debug, no debug)
  - 128-bit AES on-the-fly encryption/decryption on DDR memory, SMC, QSPI0 and QSPI1, including automatic key load at start-up. Separate keys for secure and non-secure accesses (TZAESB).
  - True random number generator compliant with NIST Special Publication 800-22 Tests Suite and FIPS PUB 140-2 and 140-3
  - Secure RTC
- Cryptography
  - SHA (SHA1, SHA224, SHA256, SHA384, SHA512) compliant with FIPS Publications 180-2
  - AES: 256-, 192-, 128-bit key algorithm, compliant with FIPS PUB 197 specifications
  - TDES: two-key or three-key algorithms, compliant with FIPS PUB 46-3 specifications
  - Public Key Coprocessor (CPKCC) and associated Classical Public Key Cryptography Library (CPKCL) for RSA, DSA, ECC GF(2^n), ECC $GF_{(p)}$[(1)]
- Up to 136 I/Os
  - Fully programmable through set/clear registers
  - Multiplexing of eight peripheral functions per I/O line
  - Each I/O line can be assigned to a peripheral or used as a general purpose I/O
  - Synchronous output, possibility to set or clear simultaneously up to 32 I/O lines in a single write
  - General purpose analog and digital inputs tolerant to positive and negative current injection
- Design for Low ElectroMagnetic Interference (EMI)
  - Slewrate-controlled I/Os
  - DDR Phy with impedance-calibrated drivers
  - Spread spectrum PLLs
  - Careful BGA power/ground ball assignment to provide optimum decoupling capacitors placement
- Microchip Recommended Power Management Integrated Circuits (PMICs)
  - MCP16502, 6-channel PMIC with I²C control interface; supports dynamic voltage scaling and processor Low-Power modes (ULP2, BSR)
  - MCP16501, 4-channel PMIC optimized for compact PCB layout; supports processor Low-Power mode (BSR)
- Junction Temperature (T_J) Range
  - Industrial : -40°C to +105°C
- Package

– 14x14 mm^2, 0.65 mm pitch, 343-ball TFBGA, optimized for standard class PCB layout (down to four layers)

Note:

1. CPKCC and CPKCL are described in the application note "Using CPKCL Version 02.08.01.xx on SAMA7G5" (document no. DS00004438). This document is available under Non-Disclosure Agreement (NDA). Contact a Microchip Sales Representative for further details.

1. Configuration Summary

Table 1-1. SAMA7G5 Configuration Summary

Feature	SAMA7G54
Package	BGA343
External memory support	NAND Flash, LPDDR2, LPDDR3, DDR2,3(L), QSPI (NAND, NOR)
Number of PIOs	136
SDMMC	3
DDR bus	16-bit
GMAC	RGMII / MII/RMII + MII / RMII
CAN-FD	6
FLEXCOM	12
ADC inputs	16
USB device/host	2/2 sharing 2 USB Type-C™ transceivers + 1 host
I2SMCC channels output/input	8/8
SSC	2
ISC	MIPI CSI-2 + Parallel RGB
PDMC channels (2 microphones per channel)	Up to 4

3. Signal Description

Table 3-1. Signal Description List

Signal Name	Function	Type	Comments	Active Level
Clocks, Oscillators and PLLs				
XIN	Main Oscillator Input	Input	–	–
XOUT	Main Oscillator Output	Output	–	–
XIN32	Slow Clock Oscillator Input	Input	–	–
XOUT32	Slow Clock Oscillator Output	Output	–	–
AUDIOCLK	Audio Clock	Output	–	–
PCK[0..7]	Programmable Clock Output	Output	Reset State: - PIO Input - Internal Pull-up enabled - Schmitt Trigger enabled	–
Shutdown, Wake-up Logic				
LPM	Low-power Mode	Output	–	–
SHDN	Shutdown Control	Output	–	–
WKUP[0..5]	Wakeup Input	Input	–	–
ICE and JTAG				
TCK/SWCLK	Test Clock/Serial Wire Clock	Input	–	–
TDI	Test Data In	Input	–	–
TDO	Test Data Out	Output	–	–
TMS/SWDIO	Test Mode Select/Serial Wire Input/Output	I/O	–	–
JTAGSEL	JTAG Selection	Input	–	–
Reset/Test				
NRST	Microprocessor Reset	Input	–	Low
TST	Test Mode Select	Input	–	–
NTRST	Test Reset Signal	Input	–	–
NRST_OUT	Microprocessor Reset Output	Output	–	Low
External Interrupt Controller - EIC				
IRQ[0..1]	External Interrupt Input	Input	–	–
PIO Controller				
PA0–PAxx	Parallel IO Controller	I/O	–	–
PB0–PBxx	Parallel IO Controller	I/O	–	–
PC0–PCxx	Parallel IO Controller	I/O	–	–
PD0–PDxx	Parallel IO Controller	I/O	–	–
PE0–PExx	Parallel IO Controller	I/O	–	–

...........continued				
Signal Name	Function	Type	Comments	Active Level
		External Bus Interface - EBI		
D[15..0]	Data Bus	I/O	–	–
A[25..0]	Address Bus	Output	–	–
NWAIT	External Wait Signal	Input	–	Low
		Static Memory Controller - SMC		
NCS[0..3]	Chip Select Lines	Output	–	Low
NWR[0..1]	Write Signal	Output	–	Low
NRD	Read Signal	Output	–	Low
NWE	Write Enable	Output	–	Low
NBS[0..1]	Byte Mask Signal	Output	–	Low
NANDOE	NAND Flash Output Enable	Output	–	Low
NANDWE	NAND Flash Write Enable	Output	–	Low
		DDR2/DDR3(L)/LPDDR2/LPDDR3 Controller		
DDR_CLK, DDR_CLKN	DDR Differential Clock	Output	–	–
DDR_CKE	DDR Clock Enable	Output	–	High
DDR_CS	DDR Controller Chip Select	Output	–	Low
DDR_BA[2..0]	Bank Select	Output	–	Low
DDR_WE	DDR Write Enable	Output	–	Low
DDR_RAS, DDR_CAS	Row and Column Signal	Output	–	Low
DDR_A[15..0]	DDR Address Bus	Output	–	–
DDR_D[15..0]	DDR Data Bus	I/O	–	–
DDR_DQS[1..0], DDR_DQSN[1..0]	Differential Data Strobe	I/O	–	–
DDR_DQM[1..0]	Write Data Mask	Output	–	–
DDR_ZQ	DDR/LPDDR Calibration	Input	–	–
DDR_VREF	DDR/LPDDR Reference	Input	–	–
DDR_RESETN	DDR3 Active Low Asynchronous Reset	Output	–	Low
DDR_ODT	DDR3 On-Die Termination	Output	–	High
		Secure Data Memory Card - SDMMCx [2..0]		
SDMMCx_CAL	SD Card Calibration	Input	–	Low
SDMMCx_CD	SD Card / e.MMC Card Detect	Input	–	Low
SDMMCx_CMD	SD Card / e.MMC Command line	I/O	–	–
SDMMCx_WP	SD Card Connector Write Protect Signal	Input	–	High
SDMMCx_RSTN	e.MMC Reset Signal	Output	–	Low
SDMMCx_1V8SEL	SD Card Signal Voltage Selection	Output	–	–

...........continued				
Signal Name	**Function**	**Type**	**Comments**	**Active Level**

Signal Name	Function	Type	Comments	Active Level
G0_RXDV/G0_CRSDV/ G0_RXCTL	Receive Data Valid or Carrier Sense and Data Valid or Receive Control Signal	Input	–	–
G0_RX[3..0]	Receive Data	Input	–	–
G0_RXER	Receive Error	Input	–	–
G0_CRS	Carrier Sense	Input	–	–
G0_COL	Collision Detect	Input	–	–
G0_MDC	Management Data Clock	Output	–	–
G0_MDIO	Management Data Input/Output	I/O	–	–
G0_TSUCOMP	TSU Timer Comparison Valid	Output	–	–
Ethernet 10/100 - GMAC1				
G1_TXCK/G1_REFCK	Transmit Clock or 50 MHz Reference Clock	I/O	–	–
G1_TXEN	Transmit Enable	Output	–	–
G1_TX[3..0]	Transmit Data	Output	–	–
G1_TXER	Transmit Coding Error	Output	–	–
G1_RXCK	Receive Clock	Input	–	–
G1_RXDV/G1_CRSDV	Receive Data Valid or Carrier Sense and Data Valid	Input	–	–
G1_RX[3..0]	Receive Data	Input	–	–
G1_RXER	Receive Error	Input	–	–
G1_CRS	Carrier Sense	Input	–	–
G1_COL	Collision Detect	Input	–	–
G1_MDC	Management Data Clock	Output	–	–
G1_MDIO	Management Data Input/Output	I/O	–	–
G1_TSUCOMP	TSU Timer Comparison Valid	Output	–	–
Analog-to-Digital Converter - ADC				
AD[0..15]	16 Analog Inputs	Analog	–	–
ADTRG	ADC Trigger	Input	–	–
ADVREFP	ADC Reference	Analog	–	–
Secure Box Module - SBM				
PIOBU[0..3]	Tamper I/Os	I/O	–	–
Image Sensor Controller - ISC				
ISC_D[0..11]	Image Sensor Data	Input	–	–
ISC_HSYNC	Image Sensor Horizontal Synchro	Input	–	–
ISC_VSYNC	Image Sensor Vertical Synchro	Input	–	–
ISC_PCK	Image Sensor Pixel clock	Input	–	–
ISC_MCK	Image Sensor Main clock	Output	–	–

...........continued				
Signal Name	**Function**	**Type**	**Comments**	**Active Level**
ISC_FIELD	Field Identification Signal	Input	–	–
Controller Area Network - CANx [5..0]				
CANRXx	CAN Receive	Input	–	–
CANTXx	CAN Transmit	Output	–	–
Pulse Density Modulation Interface Controller - PDMCx [1..0]				
PDMCx_DS[0..1]	PDM Data	Input	–	–
PDMCx_CLK	PDM Clock	Output	–	–
Sony Philips Digital Interface Receiver - SPDIFRX				
SPDIF_RX	Receive Data	Input	–	–
Sony Philips Digital Interface Transmitter - SPDIFTX				
SPDIF_TX	Transmit Data	Output	–	–
MIPI DPHY				
MIPI_DP[0..1]/ MIPI_DN[0..1]	MIPI DPHY Differential Input Data Lane 0..1	Input	–	–
MIPI_CLKP/MIPI_CLKN	MIPI DPHY Differential Input Clock Lane	Input	–	–
MIPI_REXT	Calibration Reference Resistor	Input	4.02 KΩ E96	–

4. Microchip Recommended Power Management Solutions

MCP16502 and MCP16501 are multi-channel Power Management Integrated Circuits (PMICs) designed for the SAMA7G5 series.

4.1 MCP16502 PMIC

MCP16502 is a 6-channel PMIC supporting high-performance applications requiring Digital Voltage Scaling.

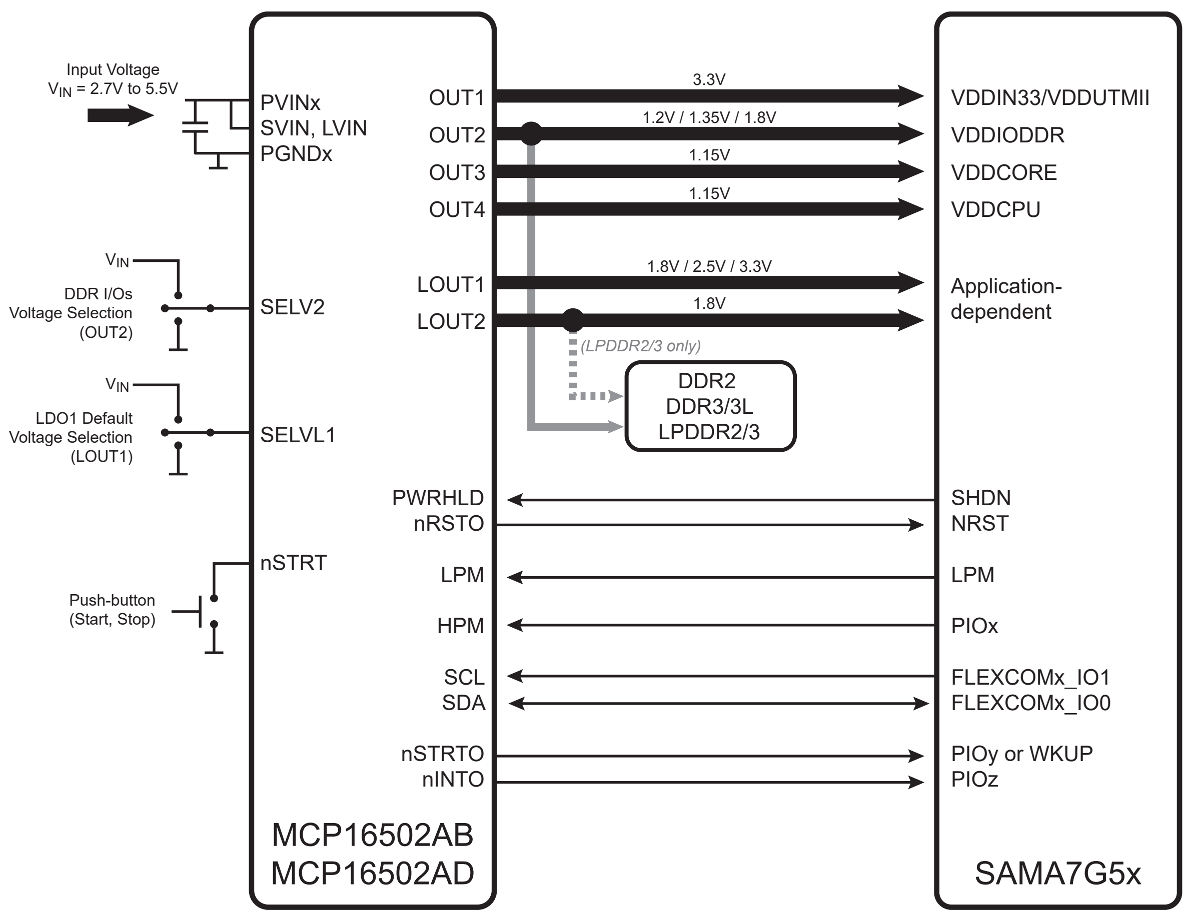
MCP16502 features four 1A DC-DC Buck regulators and two 0.3A auxiliary LDO regulators, and provides a comprehensive interface to the MPU, which includes an interrupt flag and a 1-MHz I²C interface.

The PMIC-processor interface is optimized so that it remains leakage-free in any power mode. MCP16502 supports all SAMA7G5x low-power modes. Although MCP16502 power states are fully programmable through its I²C interface, they are entered and/or exited on pin level change to ease software operations. See the following figure.

- MCP16502**AB** supports systems based on DDR2 (1.8V) or DDR3L (1.35V) SDRAM memories.
- MCP16502**AD** supports applications using LPDDR2-SDRAM or LPDDR3-SDRAM. In this version, LOUT2 is started at 1.8V.

For further details, refer to the MCP16502 documentation on www.microchip.com.

Figure 4-1. MCP16502 Simplified Application Block Diagram



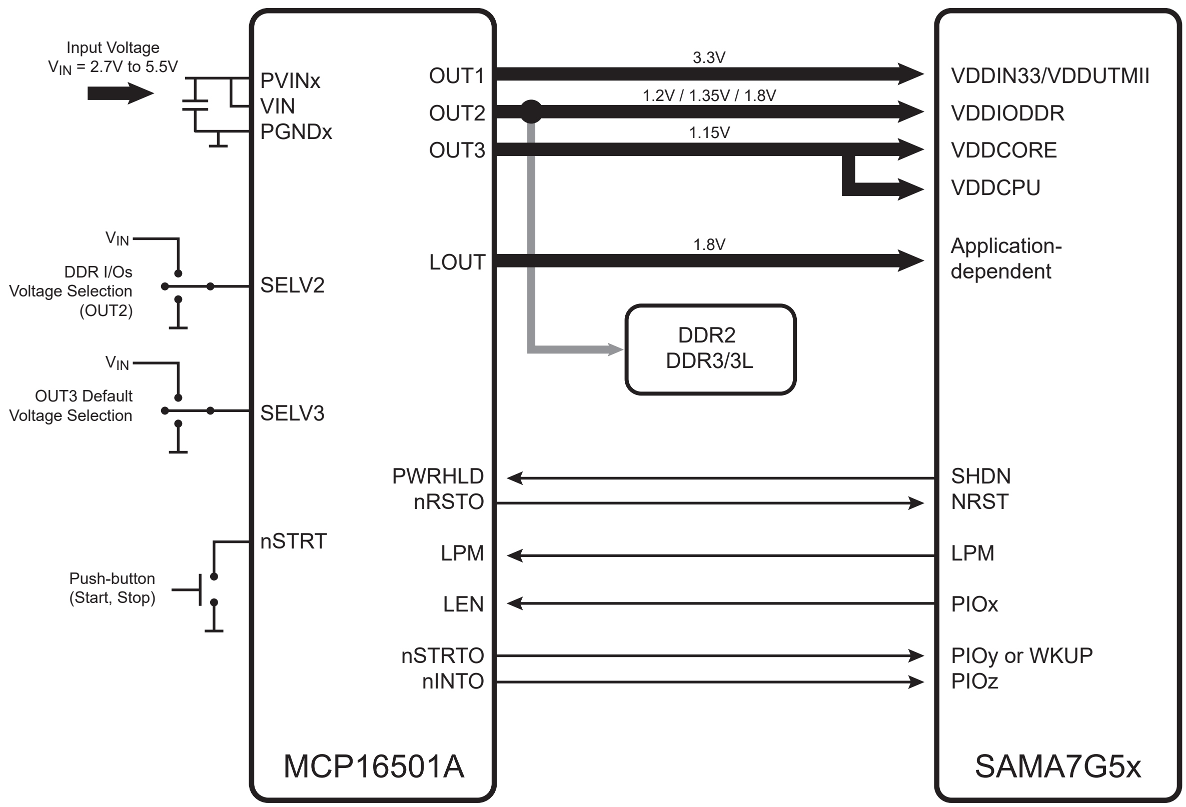
4.2 MCP16501 PMIC

MCP16501 is a 4-channel PMIC designed for PCB area constrained applications. It features three 1A DC-DC Buck regulators and one 0.3A auxiliary LDO regulator, and provides a simple, leakage-free interface with SAMA7G5. MCP16501 supports all SAMA7G5x low-power modes except ULP2, as VDDCPU is fed from the same power rail as VDDCORE. See the following figure.

- MCP16501**A** supports systems based on DDR2 (1.8V) or DDR3L (1.35V) SDRAM memories.
- MCP16501**D** supports applications using LPDDR2-SDRAM or LPDDR3-SDRAM. In this version, LOUT must be set at 1.8V and enabled by connecting LEN to OUT1.

For further details, refer to the MCP16501 documentation on www.microchip.com.

Figure 4-2. MCP16501 Simplified Application Block Diagram



5. Safety and Security Features

5.1 Design for Safety and IEC60730 Class B Certification

5.1.1 Background Information

The IEC 60730 standard encompasses all aspects of appliance design. Annex H of the standard covers the aspects most relevant to microcontrollers. It details the tests and diagnostics which are intended to ensure safe operation of embedded control hardware and software. IEC 60730 defines three classifications for electronic control functions:

- Class A - Control functions which are not intended to be relied upon for safety of the equipment
- Class B - Control functions intended to prevent unsafe operation of the controlled equipment
- Class C - Control functions intended to prevent special hazards such as explosions

Specific design techniques have been used in the SAMA7G5 to ease compliance with the IEC 60730 Class B Certification and to resolve general purpose safety concerns. This allows reduced software development and code size as well as savings on external hardware circuitry, since built-in self-tests are already embedded in the MPU. The table below gives the list of peripherals which incorporate these techniques, and details whether these features are applicable for the IEC 60730 Class B Certification or for general purpose safety considerations.

5.2 Design for Security

The SAMA7G5 embeds peripherals with security features to prevent counterfeiting, to secure external communication, and to authenticate the system.

The table below provides the list of peripherals and an overview of their security function. For more information, see the sections relevant to each peripheral.

5.3 Safety and IEC 60730 Features

Table 5-1. Safety and IEC 60730 Features List

Peripheral	Component	Fault/Error/Feature
PMC	Clock	CPU clock monitoring - Overclocking detection
		32.768 kHz crystal oscillator frequency monitoring - Abnormal frequency deviation
		Main crystal oscillator - Crystal failure detection
PIOC	I/O Periphery	Programmable configuration lock (active until next V_{DDCORE} reset) to protect against further software modifications (intentional or unintentional)
		Digital I/O - Plausibility check
ADCC		Analog I/O and ADC converter - Plausibility check
ICM (SHA)	Memory and Internal Data Path	All internal and external memories such as SMC, DDR, internal SRAM and QSPI
NAND Flash Controller ECC		Nonvolatile memory - Mutiple error detection (2 to 32)

...........continued

Peripheral	Component	Fault/Error/Feature
System Controller	Supply Monitor	Power supplies - VDDCPU, VDDCORE, VBAT abnormal levels
WDT, RSTC	Watchdog	Watchdog can be fed by an internal always on clock - Program counter stuck at faults.
		Watchdog configuration can be locked (write-protected until next reset) - Errant writes (Programming errors, errors introduced by system or hardware failures)
		Watchdog overflow generates a system reset
Cortex MMU	Memory Management Unit	Cortex-A7 Memory Management Unit
MATRIX, SYSC, ACC, PMC, PIO, SMC, SSC, I2SMCC, FLEXCOM, QSPI, TC, PDMC, ADC,ASRC, EIC, PWM, PIT64B, SPDIFRX, SPDIFTX, TZAESB, TZAESBASC, UHPHS	Peripherals	Configuration, Interrupt Enable/Disable, Control registers can be independently write-protected - Errant writes (Programming errors, errors introduced by system or hardware failures)
AES, TDES, SHA, PIT64B	Peripherals	Embedded integrity checker with reports in status registers.
AES, TDES	Peripherals	Immediate clear of keys in case of tamper detection. Immediate stop of processing in case of tamper detection
PWM, PIO	PWM	Fault inputs can be configured to put the PWM outputs in Safe mode - Programming errors, errors introduced by system or hardware failures
		PIO controller can lock the PWM I/O - Programming errors, errors introduced by system or hardware failures
		Fault inputs can be external (IO) or internal (ADC, TIMER, ACC, etc.) - Programming errors, errors introduced by system or hardware failures

5.4 Security Features

Table 5-2. Security Features

Peripheral	Function	Description	Comments
TrustZone	Security Enclave	Partition Secure/Non-secure world	Arm technology
Cortex MMU	Memory Management Unit	Cortex-A7 Memory Management Unit	–
PIO	I/O Control/ Peripheral Access	When a peripheral is not selected (PIO-controlled), IO lines have no access to the peripheral.	–
	Freeze	Capability to freeze either the functional part or the physical part of the configuration.	Once the freeze command is issued, no modifications to the current configuration are possible. Only a hardware reset allows a change to the configuration.

...........continued

Peripheral	Function	Description	Comments
Public Key Coprocessor (CPKCC) and associated Classical Public Key Cryptography Library (CPKCL)	Cryptography	ECC (Asymmetric key algorithm, elliptic curves)	–
		RSA (Asymmetric key algorithm)	
TDES, TRNG, AES, SHA		Hardware-accelerated Triple DES	FIPS-compliant[(1)]
		True Random Number Generator	
		Hardware-accelerated AES up to 256 bits	
		SHA up to 512 and HMAC-SHA	
AES, SHA, CPKCC, CPKLC	Secure Boot	Code encrypted/decrypted, Trusted Code Authentication	Hardware AES: Encrypt, Decrypt, CMAC Hardware SHA CPKCC, CPKCL: RSA or elliptic curves
AES, TDES, SHA, PIT64B, TC	Security and safety analysis and report	Monitoring on states or sequences, clocks and waveforms. Error detection can occur only in abnormal operating conditions.	–
	Register access protection	Checks for incorrect accesses.	–
AES, TDES	Key clearing on event	Immediate clearing of the key in case of external tamper event detection	–
TZAESB	On-the-fly AES	On-the-fly encryption/decryption for NFC_RAM, DDR, QSPI and SMC memories, with respect to TrustZone using TZAESBASC	AES128
TZAESBASC		Directs data transfer to either the TZAESB secure core or the unsecured TZAESB core	–
Private Key Bus	Transfers hidden keys to crypto-engines	Capability to transfer keys to or from AES, TZAESB, TDES, TRNG, OTPC in a manner totally invisible by the software.	–
Memories	Scrambling	On-the-fly scrambling/unscrambling for memories	SMC, SECURAM, GPBR and QSPI
ICM	Memory Integrity Check Monitoring	Uses a hardware Secure Hash Algorithm (up to SHA256)	SMC, DDR, internal SRAM and QSPI

...........continued

Peripheral	Function	Description	Comments
SECUMOD	JTAG	JTAG entry monitor	These tampers (JTAG, test, PIOBUs, monitors, etc.) can be configured to immediately erase Backup memories (BUSRAM4KB and BUREG256b) or generate an interrupt or a wakeup signal.
	Test	Test entry monitor	
	Voltage Monitoring	VBAT monitoring	
		VDDCPU monitoring	
		VDDCORE monitoring	
	Temperature Monitoring	Temperature monitoring	
	Frequency Monitoring	32.768 kHz crystal oscillator monitoring	
		CPU clock monitoring	
	IO Tamper Pin	4 tamper detection pins. Active and Dynamic modes supported.	
	Secure Backup SRAM (SECURAM)	5 Kbytes scrambled and non-imprinting avoiding data persistance	4 Kbytes erasable on tamper detection
	Secure Backup Registers	256-bit register bank, scrambled	Erasable on tamper detection
RTC	RTC	Timestamping of tamper events. Protection against bad configuration (invalid entry for date and time are impossible)	All events are logged in the RTC. Timestamping gives the source of the reset/ erase memory/interruption
		RTC robustness against glitch attack on 32 kHz crystal oscillator	–
Secure OTP	JTAG Access Control	Disable JTAG access by OTP bit	–
	Secure Debug Disable	JTAG debug allowed in Normal mode only, not in Secure mode	TrustZone
TZWDT	Watchdog	Protects against TrustZone starvation	TrustZone
GPBR	Peripheral Access and Protection	GPBR can be write protected, read protected and immediately cleared on external tamper event detection	–

Note:
1. Refer to each peripheral section for details on FIPS compliance.

6. Event System

A set of events generated by "source" peripherals are routed to "destination" peripherals without processor intervention.

6.1 Real-Time Event List

- Timers, PWM, and IO peripherals generate event triggers which are directly routed to event managers such as ADC, for example, to start measurement/conversion without processor intervention.
- ADC is connected to nine trigger inputs defined as two groups:
  – One group of eight elements for Timer Counter (TC0 to TC4), ADTRIG and PMW0 event0, PWM0 event1
  – One group of one element for low-rate trigger, RTC
- PWM safety events (faults) are in combinational form and directly routed from event generators (ADC, ACC, PMC, TIMER) to the PWM module.
- PWM output comparators generate events directly connected to TIMER.
- PMC safety event (clock failure detection) can be programmed to switch the MCK on a reliable main RC internal clock without processor intervention.

6.2 Real-Time Event Mapping

Table 6-1. Real-Time Event Mapping List

Function	Application	Description	Event Source	Event Destination
Safety	General-purpose	Automatic switch to reliable main RC oscillator in case of main crystal clock failure(1)	Power Management Controller (PMC)	PMC
	General-purpose, motor control, Power Factor Correction (PFC)	Puts the PWM outputs in Safe mode in case of main crystal clock failure(1)(2)	PMC	Pulse Width Modulation (PWM)
	Motor control, PFC	Puts the PWM outputs in Safe mode (overcurrent detection, etc.)(2)(3)	Analog-to-Digital Converter (ADC)	PWM
	Motor control	Puts the PWM outputs in Safe mode (overspeed detection through timer quadrature decoder)(2)(4)	TC0 PWM FAULT	PWM
	General-purpose, motor control, PFC	Puts the PWM outputs in Safe mode (general-purpose fault inputs)(2)	PWM_FIx	PWM

...........continued

Function	Application	Description	Event Source	Event Destination
Measurement trigger	Power factor correction (DC-DC, lighting, etc.)	Duty cycle output waveform correction Trigger source selection in PWM(5)(6)	ACC	PWM
			PWM_EXTRGx	PWM
	General-purpose	Trigger source selection in ADCC(7)	PIO ADTRG	ADCC
			TC0 TIOA0	ADCC
			TC0 TIOA1	ADCC
			TC0 TIOA2	ADCC
			TC1 TIOA3	ADCC
			ACC	ADCC
	Motor control	ADC-PWM synchronization(10)(11) Trigger source selection in ADCC(7)	PWM event lines 0 and 1	ADCC
	General-purpose	Temperature sensor Low-speed measurement(10)(11)	RTC RTCOUT0	ADCC
Delay measurement	Motor control	Propagation delay of external components (IOs, power transistor bridge driver, etc.)(12)(13)	PWM comparator output OC0	TC0, TIOA0 and TIOB0
			PWM comparator output OC1	TC0, TIOA1 and TIOB1
			PWM comparator output OC2	TC0, TIOA2 and TIOB2
Audio clock recovery from Ethernet	Audio	GMAC GTSUCOMP signal adaptation via TC (TC_EMR.TRIGSRCB) in order to drive the clock reference of the external PLL for the audio clock	GMAC0 GTSUCOMP	TC1 TIOB1
Direct Memory Access	General-purpose	Peripheral trigger event generation to transfer data to/from system memory(14)	Peripherals with DMA HW interface number	XDMA0
				XDMA1
Wake-up	Wake On LAN	GMAC uses WOL frame comparison and wake-up the core by enabling the crystal	GMAC0, GMAC1	PMC

Notes:

1. Refer to Main Crystal Oscillator Failure Detection in the section Power Management Controller (PMC).
2. Refer to Fault Inputs and Fault Protection in the section Pulse Width Modulation Controller (PWM).
3. Refer to Fault Mode in the section Analog Comparator Controller (ACC).
4. Refer to Fault Mode in the section Analog Comparator Controller (ACC).
5. Refer to PWM_ETRGx in the section Pulse Width Modulation Controller (PWM).
6. Refer to PWM External Trigger Mode in the section Pulse Width Modulation Controller (PWM).
7. Refer to Conversion Triggers in the section Analog-to-Digital Converter (ADC).
8. Refer to Temperature Sensor in the section Analog-to-Digital Converter (ADC).
9. Refer to Waveform Generation in the section Real-time Clock (RTC).
10. Refer to PWM_CMPVx in the section Pulse Width Modulation Controller (PWM).
11. Refer to PWM Comparison Units and PWM Event Lines in the section Pulse Width Modulation Controller (PWM).
12. Refer to Comparator in the section Pulse Width Modulation Controller (PWM).
13. Refer to Synchronization with PWM in the section Timer Counter (TC).
14. Refer to the section DMA Controller (XDMAC).

7. Package and Pinout

7.1 Package

The SAMA7G5 is available in the following package:

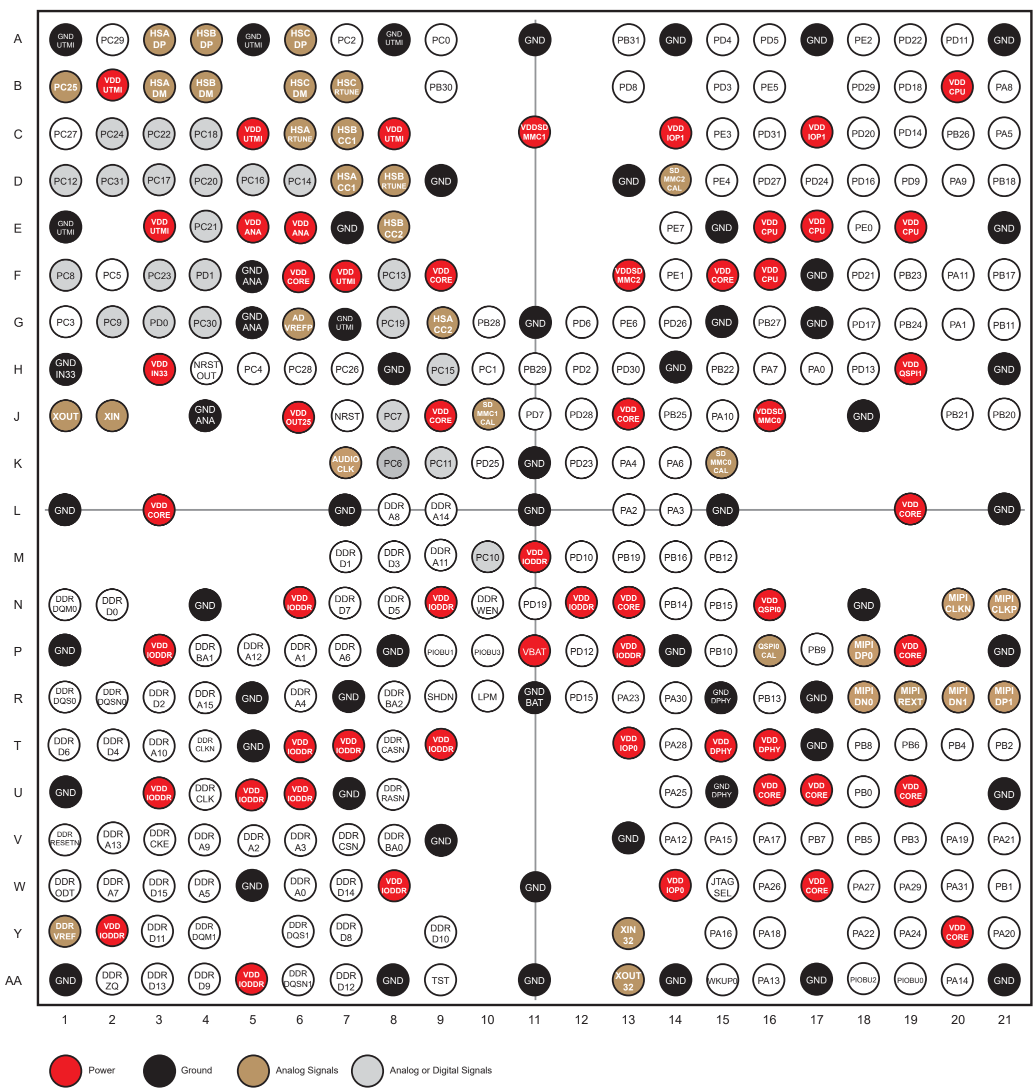
- 14x14 mm^2, 0.65-mm pitch 343-ball TFBGA optimized for 4-layer PCB

For further details, refer to Mechanical Characteristics.

7.2 Pinout

7.2.1 BGA343 Pinout

Figure 7-1. 343-ball TFBGA Pinout



The device features several PIO controllers that multiplex the I/O lines of the peripheral set. The following Pin Description table defines how the I/O lines are multiplexed on the different PIO controllers. The "Reset State" column shows whether the PIO line resets in I/O mode or in Peripheral mode. If I/O is shown, the PIO line resets with the characteristics (input, output, pull-up or pull-down) indicated in this same column, so that the device is configured in a known state as soon as the reset is released. As a result, PIO_CFGR.FUNC resets to ‘0’. If a signal name is shown in the “Reset State” column, the PIO line is assigned to this function and PIO_CFGR.FUNC is not set to ‘0’. That is the case for pins controlling memories, in particular address lines, which require the pin to be driven as soon as the reset is released.

Table 7-1. Pin Description[(1)(2)]

343-pin TFBGA	Power Rail	I/O Type	Primary		Alternate		PIO Peripheral				Reset State

Notes:

1. I/Os for each peripheral are grouped into I/O sets, listed in the column "I/O Set". For all peripherals, use I/Os that belong to the same I/O set. Timings can be unpredictable when I/Os from different I/O sets are mixed.
2. When using an I/O line with the Analog-to-Digital Converter (ADC) or with the Analog Comparator Controller (ACC), the PIO line configuration (pull-up, pull-down) programmed before assigning this line to the ADC or ACC peripheral is not modified by this peripheral.
3. This is the PIOBU state after VBAT power-up. If programmed to another value, this value is maintained as long as VBAT is not removed.

8. System Interconnect and Security (SIS)

8.1 System Bus and Interconnect

The device on-chip interconnect is architectured around the following components:

- 5x AXI matrixes based on the Arm NIC-400 module
- 1x AHB matrix
- 8x APB buses
- 1x Universal DDR Memory Controller (UDDRC)

The following features are supported by the interconnect backbone:

- Quality of Service (QoS) to ensure priorities and limits for all AXI and AHB transactions
- Performance monitoring to track AXI bus activity

8.1.2 AXI Subsystem

The AXI subsystem is comprised of:

- CSS — CPU System and Security matrix
- CHS — CPU High Speed matrix
- APS — APB Client matrix
- AXM — AXI Hosts matrix
- ISS — Image Subsystem

AXI matrixes are based on NIC-400 r1p1 (by Arm Ltd.) and no settings are controlled by software. The respective hardware configurations used are given in the following sections. The default software configuration has been intensively tested and leads to best results in any conditions.

For complete details on the NIC-400 design, see the Arm specification on http://infocenter.arm.com/help/topic/com.arm.doc.ddi0475h/index.html

The device embeds Quality of Service management provided by Arm QoS-400 supplement to NIC-400. QoS-400 r1p1 is controlled by software. The respective hardware configurations used are given in the following sections. The default software configuration has been intensively tested and leads to best results in any conditions.

For complete details on the QoS-400, see the Arm specification on http://infocenter.arm.com/help/index.jsp?topic=/com.arm.doc.dsu0026g/index.html

This AXI subsystem (NICGPV) is connected to peripherals and to an AHB matrix (MATRIX) described below.

The following tables summarize the AXI matrix hosts and clients.

Table 8-2. AXI Hosts

Notes:
1. Refer to the following sections for details on each configuration method.
2. “AS” stands for Always Secure; this configuration cannot be changed.

8.3 Quality of Service (QoS) Overview

Quality of Service is extremely important in distributing the available resources (bandwidth or latency) among devices to meet overall performance requirements.

In the circuit, multiple hosts communicate with clients through interconnect. However, bandwidth-sensitive hosts can starve for data and latency-sensitive host requirements can be unsatisfied. This impacts the overall performance of the subsystem. QoS and Outstanding Capability address these types of performance issues in the subsystem.

Configuration can be done in different locations: NIC-400 Global Programmer's View (NICGPV), MATRIX, peripheral, UDDR Controller or SFR register.

Some peripherals embed bandwidth regulation. This feature is located in the NICGPV.

8.3.1 Cortex-A7 CPU

The Cortex-A7 CPU does not generate its own QoS. The CPU QoS is programmable in the interconnect matrix through the NICGPV registers.

The ASIB block that generates the ARQOS and AWQOS signals is configured through register ASIB[0].

8.3.2 DMA

8.3.2.1 DMA Per Queue Outstanding Capabilities

- Each XDMA transfer stream is managed by 7 transfer queues (3 for write operations, 4 for read operations).

- The outstanding capability of each of those queues is configurable through the XDMAC_GCFG register fields.
- Each queue has a static priority versus the other queues.

Register fields:

- XDMAC_GCFG.WRHP : write outstanding for peripheral write of a memory-to-peripheral DMA channel (highest write priority)
- XDMAC_GCFG.WRMP: write outstanding for memory write of a peripheral-to-memory DMA channel (medium write priority)
- XDMAC_GCFG.WRLP: write outstanding for memory write of a memory-to-memory DMA channel (lowest write priority)
- XDMAC_GCFG.RDHP: read outstanding for peripheral read of a peripheral-to-memory DMA channel (high read priority)
- XDMAC_GCFG.RDMP: read outstanding for memory read of a memory-to-peripheral DMA channel (medium read priority)
- XDMAC_GCFG.RDSP: read outstanding for transfer descriptor read of all types of DMA channel (highest priority)

8.3.2.2 DMA Per Queue Outstanding Capabilities

- Each channel QoS is configured through a 2-bit wide register: XDMAC_CNDC[channel number].qos.
- The 2-bit XDMAC_CNDC[channel number].qos value is duplicated to form a 4-bit bus that connects XDMAs to the UDDRC through the interconnect, therefore not all 4-bit QoS values are available.
  Possible values = {0, 0x5, 0xA, 0xF}.
- The XDMAC_CNDC[channel number].qos is only used by the following DMA transactions:
  – Read New Descriptor
  – Write Last Burst of Data before Reading New Descriptor
- For all other DMA transfers, the 4-bit QOS is 0 (lowest priority).

Register fields:

- XDMAC_CNDC[channel_number].qos = 3 for channel_number in [31:0] for XDMA0
- XDMAC_CNDC[channel_number].qos = 3 for channel_number in [31:0] for XDMA1
- XDMAC_CNDC[channel_number].qos = 0 for channel_number in [7:0] for XDMA2

8.3.3 GMAC

8.3.3.1 GMAC Outstanding Capabilities

GMAC0-1 are implemented with maximum hardware outstanding capability of four AXI read transactions and four AXI write transactions.

Register field:

The GMAC_AMP (GMAC AXI Max Pipeline) register is used to set the real outstanding capability for each GMAC (lower than the maximum implemented capability).

8.3.3.2 GMAC QoS

GMAC does not generate its own QoS. GMAC QoS is programmable in the interconnect matrix through the NICGPV registers.

The ASIB block that generates the ARQOS and AWQOS signals is configured through register ASIB[5] for GMAC0 and ASIB[6] for GMAC1.

8.3.4 SDMMC

SDMMC provides a QoS programming for AHB accesses when fetching descriptors in SDMMC0_ACR register. For all other accesses, the QOS is set to 0.

8.3.5 ISC

ISC provides dynamic (host-generated) QoS information in ISC_DCFG register. If AWQOS is set to 0, the QoS value depends on the output FIFO level (dynamic configuration). Otherwise, the value is defined in the register. ARQOS[3:0] returns the QoS bus value when a descriptor is retrieved from the memory.

8.3.6 AHB

The AHB matrix (MATRIX) provides two mechanisms:

- One inside MATRIX for each port, with registers MATRIX_PRAS[port number], MATRIX_PRBS[port number]
- One for the AHB to AXI bridge, with register SFR_HSS_AXIQOS

8.3.7 UDDRC

The five ports are configured with PCFGQOS0_[port number], PCFGQOS1_[port number], PCFGWQOS0_[port number], PCFGWQOS1_[port number].

The following table summarizes how to program Outstanding Capability in each applicable section.

Table 8-7. Outstanding Capability Programming

Instance	AXI Outstanding Management
DMA0	XDMAC0_GCFG.WRHP, XDMAC0_GCFG.WRMP, XDMAC0_GCFG.WRLP, XDMAC0_GCFG.RDHP, XDMAC0_GCFG.RDMP, XDMAC0_GCFG.RDSP
DMA1	XDMAC1_GCFG.WRHP, XDMAC1_GCFG.WRMP, XDMAC1_GCFG.WRLP, XDMAC1_GCFG.RDHP, XDMAC1_GCFG.RDMP, XDMAC1_GCFG.RDSP
DMA2	XDMAC2_GCFG.WRHP, XDMAC2_GCFG.WRMP, XDMAC2_GCFG.WRLP, XDMAC2_GCFG.RDHP, XDMAC2_GCFG.RDMP, XDMAC2_GCFG.RDSP
GMAC0	GMAC0_AMP register
GMAC1	GMAC1_AMP register

The following table summarizes how to program QoS in each applicable section.

Table 8-8. Quality of Service Programming

Instance	QoS Management	Default Value	Transaction Outstanding Latency Regulation in NICGPV
CPU	ASIB[0] in NICGPV[(1)]	0	–
DMA0, per channel	QoS in XDMAC0_CNDC[channel number] registers	0	–
DMA1, per channel	QoS in XDMAC1_CNDC[channel number] registers	0	–
DMA2, per channel	QoS in XDMAC2_CNDC[channel number] registers	0	X
GMAC0	ASIB[5] in NICGPV	0	X
GMAC1	ASIB[6] in NICGPV	0	X
SDMMC0	Peripheral for descriptors, in SDMMC0_ACR register	0	X
SDMMC1	Peripheral for descriptors, in SDMMC1_ACR register	0	X
SDMMC2	Peripheral for descriptors, in SDMMC2_ACR register	0	X
ISC	Peripheral in ISC_DCFG register	0	–
AHB matrix port 3	SFR_HSS_AXIQOS Register	0	–
DDR port, per port	UDDRC in PCFGQOS0_[port number], PCFGQOS1_[port number], PCFGWQOS0_[port number], PCFGWQOS1_[port number] registers	0	–

...........continued			
Instance	QoS Management	Default Value	Transaction Outstanding Latency Regulation in NICGPV
AHB matrix hosts (including CPU)	MATRIX_PRAS[port number] MATRIX_PRBS[port number]	0 2	–

Note:
1. This QoS is not propagated to the AHB matrix through the M0 port.

For details, refer to the relevant peripheral sections and to 12. NIC-400 Global Programmer's View (NICGPV), 13. Bus Matrix (MATRIX) and 31. Special Function Registers (SFR).

8.4 TrustZone Security Management

The device architecture embeds several mechanisms for system TrustZone configuration:

- Core security extensions
- TrustZone Peripheral Manager (TZPM) for peripheral configuration
- TrustZone registers in the AHB matrix (MATRIX) for host configuration and memory configuration (except for DDR)
- TrustZone Address Space Controller (TZC) based on Arm TZC400 modules for DDR access configuration
- TrustZone AESB Address Space Controller (TZAESBASC) for on-the-fly encrypted memory zone access

Important: The above TrustZone management mechanisms use separate configuration interfaces. Some memories or IPs may be configured by many of those mechanisms. In such case, consistency must be ensured between configurations.

8.4.1 TrustZone System Overview

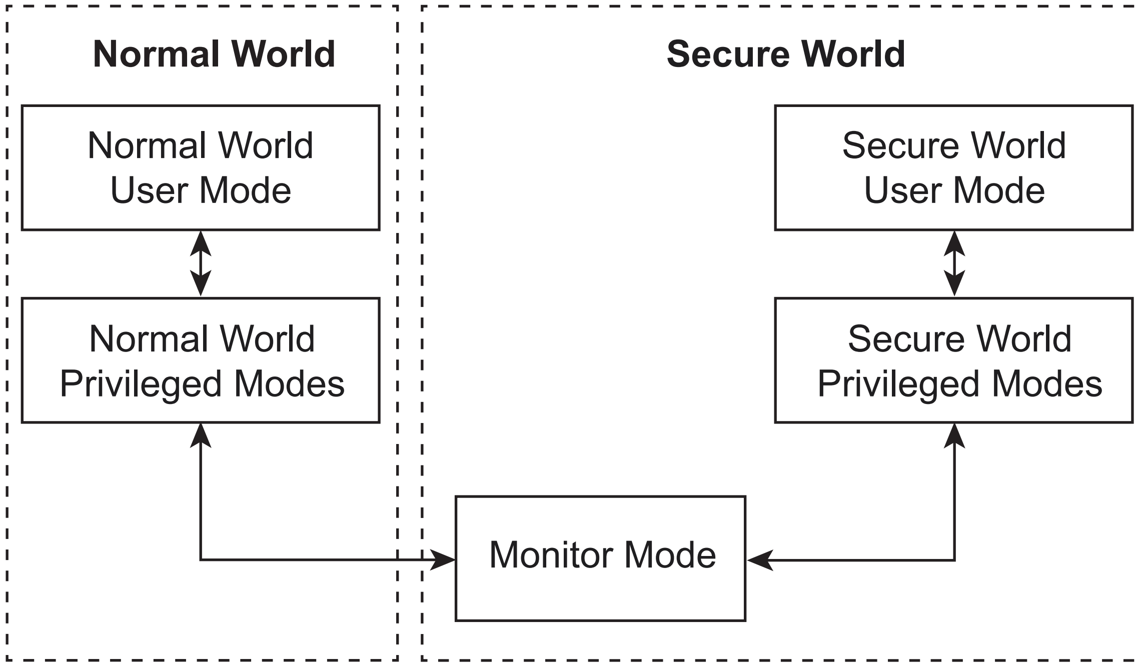
8.4.1.1 Hardware

TrustZone enables a single physical processor core to execute code safely and efficiently from both the Normal world and the Secure world. This removes the need for a dedicated security processor core, saving silicon area and power, and allowing high performance security software to run alongside the Normal world operating environment.

The two virtual processors switch contexts via Monitor mode when changing the currently running virtual processor.

See the following figure.

Figure 8-2. TrustZone Hardware Implementation



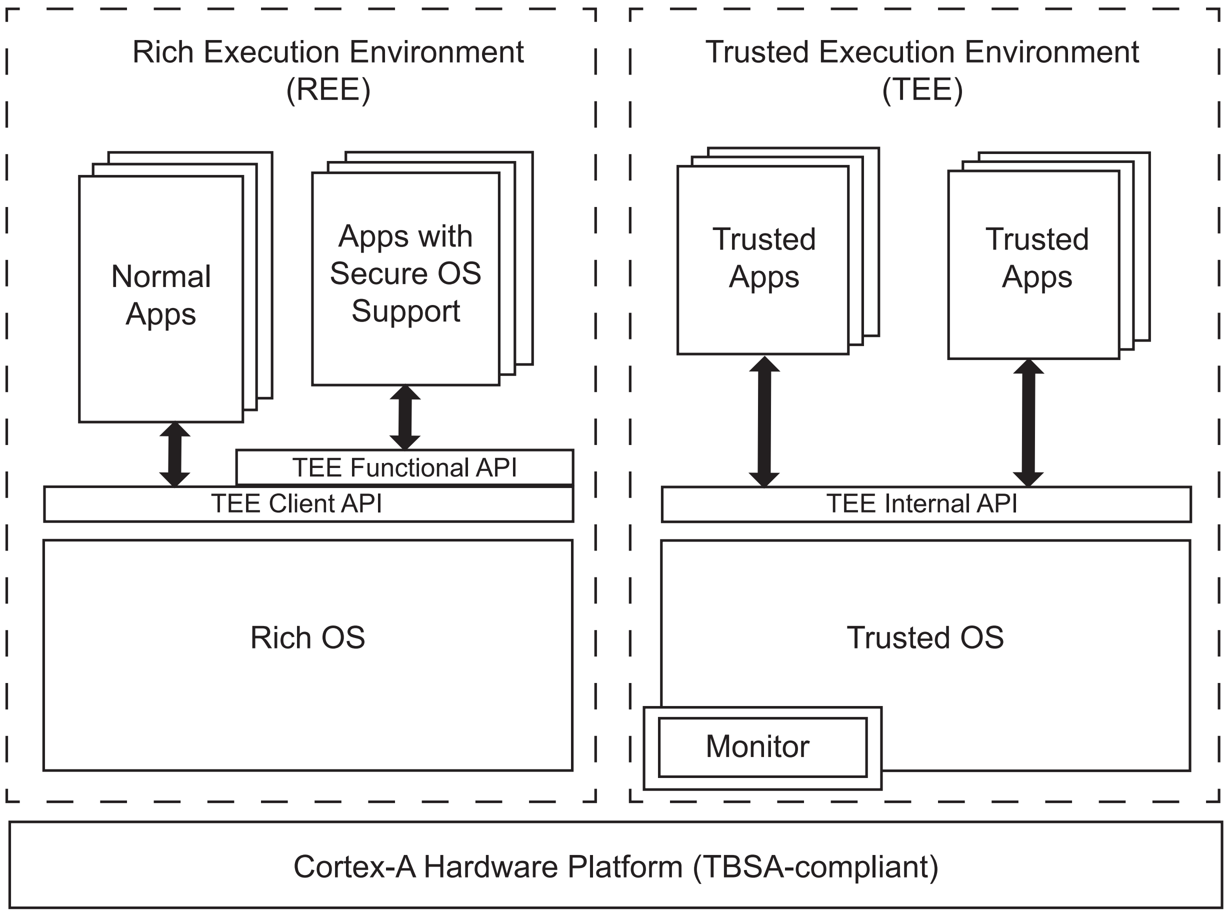
8.4.1.2 Software

The mechanisms by which the physical processor can enter Monitor mode from the Normal world are tightly controlled, and are all viewed as exceptions to the Monitor mode software. Software executing a dedicated instruction can trigger entry to monitor, the Secure Monitor Call (SMC) instruction, or by a subset of the hardware exception mechanisms. Configuration of the IRQ, external Data Abort, and external Prefetch Abort exceptions can cause the processor to switch to Monitor mode.

The software executed within Monitor mode is implementation-defined, but it generally saves the state of the current world and restores the state of the world at the location to which it switches. It then performs a return-from-exception to restart processing in the restored world.

See the following figure.

Figure 8-3. TrustZone Software Implementation in a Trusted Execution Environment (TEE)



8.4.1.3 Debug

The TrustZone hardware architecture is a security-aware debug infrastructure that can enable control over access to Secure world debug without impairing debug visibility of the Normal world. Arm CoreSight infrastructure uses four signals to control authentication:

- DBGEN – Non-secure invasive debug enable
- NIDEN – Non-secure non-invasive debug enable
- SPIDEN – Secure invasive debug enable
- SPNIDEN – Secure non-invasive debug enable

These signals allow several Debug modes and are managed in the Security Module. Refer to the section Security Module (SECUMOD) for more details.

8.4.2 Core Security Extensions Overview

The purpose of the security extensions is to enable the construction of a secure software environment.

When the Cortex-A7 processor is executing in Non-secure state, the processor performs translation table look-ups using the Non-secure versions of the translation table base registers. In this situation, any virtual address (VA) can only translate into a Non-secure physical address (PA). In Secure state, the Cortex-A7 processor performs translation table look-ups using the Secure versions of the translation table base registers. In this situation, the security state of any VA is determined by the NS bit of the translation table descriptors for that address.

Following is an example of the address manipulation that occurs when the Cortex-A7 processor requests an instruction:

1. The Cortex-A7 processor issues the instruction VA as a Secure or Non-secure VA.

2. The instruction cache is indexed by the VA bits. The MMU performs the translation table look-up in parallel with the cache access. If the processor is in the Secure state it uses the Secure translation tables, otherwise it uses the Non-secure translation tables.
3. If the protection check carried out by the MMU on the VA does not abort and the PA tag is in the instruction cache, the instruction data is returned to the processor.
4. If there is a cache miss, the MMU passes the PA to the AXI bus interface to perform an external access. The external access is always Non-secure when the core is in the Non-secure state. In the Secure state, the external access is Secure or Non-secure according to the NS attribute value in the selected translation table entry. In Secure state, both L1 and L2 translation table walk accesses are marked as Secure, even if the first level descriptor is marked as NS.

Refer to the *Arm Architecture Reference Manual, Arm v7-A and Arm v7-R edition* for details on security extensions.

8.4.3 TrustZone Peripheral Manager (TZPM)

8.4.3.1 Function

The TrustZone Peripheral Manager (TZPM) controls the access permissions to peripherals (in other words, whether or not the Non-secure world is allowed to access the peripherals). For peripherals with a bus host interface, the TZPM controls at the same time the security of host accesses transmitted by these peripherals.

The permission for each peripheral access is controlled by a dedicated security bit, the index of which is equal to the peripheral ID (unless Exceptions apply) with:

- 1: Peripheral is not secure
- 0: Peripheral is secure (cannot be accessed by Non-secure world)

128 security bits, controlling up to 128 peripherals, are organized in four registers (TZPM_PIDR0 to 3). Each register can be written if TZPM_KEY is written previously with the correct key.

- For Always Secure (AS) peripherals, the corresponding bit value is 0 and read-only.
- For Never Secure (NS) peripherals, the corresponding bit value is 1 and read-only.
- For Programmable Secure (PS) peripherals, the corresponding bit value is 0 (Secure) after reset and can be modified.

For details, see TZPM registers, Peripheral Clocks and Security and the table Peripheral Identifiers.

8.4.3.2 Example

For FLEXCOM2, the peripheral ID is ID_FLEXCOM2 = 40, requiring modification of bit TZPM_PIDR1[8].

- TZPM_KEY = 0x12AC4B5D
- TZPM_PIDR1 = 0x100

8.4.3.3 Exceptions

Not all bits are coded. In several cases, the peripheral security access is not controlled through the TZPM: Always Secure IDs, TZC400 protected IDs, specific IPs (secure DMA, OTP).

For some peripherals, the bit index controlling the access permission differs from the peripheral ID. This is the case when several peripherals share a common security bit:

- CSI, CSI2DC and ISC permissions are controlled by the bit index ID_ISC.
- DDRPUBL and DDRUMCTL permissions are controlled by the bit index ID_DDRPUBL.

Some peripheral IDs do not correspond to a peripheral user interface but only to an interrupt (ex: ID_AES_SINT). In this case, the security bit is read-only and generally equal to zero except when the associated interrupt targets only the Non-secure world. Note that the security bit value should be considered as don't-care for interrupt-only IDs.

Some peripheral IDs are not assigned to any functionality (“reserved”). The corresponding security bit is 0 (don't care), read-only.

ID_TZAESB_NS is the only programmable-secure peripheral with value 1 (not secure) after reset.

ID_UHPHS is the only programmable-secure peripheral with user interface security controlled by HMatrix programming. The corresponding TZPM bit only controls the security of USB host ports, due to the fact that the USB Host is a native AHB peripheral and is plugged directly on HMatrix (not plugged on an HBridge).

8.4.3.4 Bus Hosts

The security bits set in the TZPM control the security of bus accesses generated by the hosts. As an example, if the security bit of ID_GMAC0 is set to secure, GMAC0 will perform secure host accesses on the bus. It is not possible to have different permission levels on the user (client) interface and on the host interface. Peripherals are either only accessible by the Secure world and generate secure host accesses, or are accessible by all worlds and generate Non-secure host accesses.

Notes:

1. As any peripheral, TZPM has a dedicated peripheral ID with a corresponding security bit controlled in TZPM_PIDR registers. However, TZPM is Always Secure, so this bit is read 0, read-only.
2. Some “interrupt only” type peripheral IDs may be greater than 127 (which is the maximum ID TZPM can control). All peripherals with a user interface have an ID number below 127 in order to be controllable by TZPM.
3. The security bit value of peripheral IDs can conflict with the security level of interrupt IDs. In this case, the security level of the peripheral prevails. Remember that the security bit value information is not very important for interrupts since there is no hardware mechanism using the security bit to route the interrupts to Secure or Non-secure worlds. Interrupt security is entirely controlled by GIC programming.

Peripheral ID	Type	Security
ID_TZPM	User interface	Always Secure

8.4.3.5 Register Summary

Offset	Name	Bit Pos.	7	6	5	4	3	2	1	0

Value	Description
0	Secure accesses only.
1	Non-secure accesses are allowed.

8.4.4 AHB Matrix (MATRIX)

8.4.4.1 Function

The AHB matrix defines security regions in the memory space. It also retrieves information after access denial events through interrupts. MATRIX covers the memory space not covered by TZPM and targets internal or external memories, except for DDR.

Peripheral ID	Type	Security
ID_MATRIX	User interface	Always Secure

8.4.4.2 Programming

Depending on its configuration and current request, the MATRIX grants or denies access to the memory areas. The Static Memory Controller (SMC), connected on S7 port, contains several configurable memory areas. These are EBI_CS0, EBI_CS1, EBI_CS2, EBI_CS3 and NFC_CMD, with respective HSEL from HSEL0 to HSEL4. For internal memory NFC_CMD, the top address is known so only MATRIX Security Areas Split Client Register 7 (MATRIX_SASSR7) is to be programmed.

Refer to the section “Bus Matrix (MATRIX)”.

8.4.5 TrustZone Address Space Controller (TZC400)

The TrustZone Controller is based on TZC400 r0p1 (by Arm Ltd.) and is highly configurable at the hardware design stage. Several options are controlled by software. The respective hardware configurations used are given in table

TZC Controller and DDR Ports. The default software configuration has been intensively tested and leads to best results in any conditions.

For complete details on the TZC400 design, refer to www.arm.com/products/silicon-ip-security/tzc-400.

8.4.5.1 Function

The TZC400 is dedicated to DDR security settings. As the DDR controller features five client ports and the maximum number of ports on a TZC400 is four, two TZC400 controllers are integrated. A 1-port TZC400 is used between the processor and the DDR, while the other four ports are secured through a 4-port TZC400. See the following table for the association of TZC ports and DDR ports.

Table 8-9. TZC Controller and DDR Ports

TZC Controller	TZC Port	DDR Port
0	0	Port 1 (TZAESB, QSPI, USB, EBI, ICM)
0	1	Port 2 (DMA0, DMA1)
0	2	Port 3 (ISC)
0	3	Port 4 (GMAC0-1, SDMMC0-2, DMA2)
1	0	Port 0 (CPU)

8.4.5.2 Filters

On the TZC400, each port has its own dedicated filter. Each filter must be configured by software; up to nine regions can be associated to a filter. A region is a memory space with particular access permissions.

TZC0 and TZC1 regions must be programmed in a consistent way. For each region, program Region ID Access register as follows:

- Set bit 0 (NSAID_RD_EN field) to allow NS read accesses. The bit default value is 0 and only S read accesses are allowed.
- Set bit 16 (NSAID_WD_EN field) to allow NS write accesses. The bit default value is 0 and only S write accesses are allowed.

Region 0 is the background region and defines the two extremities of the accessible memory range and the default access permission. This region is not optional. Accessing an address out of region 0 is always denied.

Up to eight additional regions can be defined and superimposed on region 0 but must never overlap each other. Each region can describe different access permissions (read enabled, write enabled, secure access rights, not secure access rights).

Finally, different regions can be associated to different ports (or, simply, the same regions can be associated to all ports).

In case of access permission violation, an interrupt can be generated, and denied access information (address, port, type, etc.) can be retrieved in Status registers. An interrupt can also be issued in case of programming errors (overlapping regions, for example).

Note:
The two TZC400 controllers have been merged into a combined 5-port TZC400. There is only one interrupt line, comprised of ORed interrupts of the two controllers.

After reset, the TZC400 blocks all accesses to DDR. It must be configured before any DDR access. The DDRC clock must be enabled before configuring TZC400.

Speculative access is forbidden in order to prevent the TZC400 from propagating accesses even when they fail the security permissions (this would not result in any successful access, but would lead to some visible activity on DDR ports). This restriction implies that the 'fast path' feature cannot be used in TZC400 (this feature offers more bandwidth but requires setting Speculative Access mode).

Peripheral ID	Type	Security
ID_TZC	User interface	Always Secure

8.4.6 Programmable IO Controller (PIOC)

The PIO controller memory map is split in two parts: the lower 4 Kbytes are never secure, while the upper part is always secure. Each IO line can be configured as secure or non-secure. Once configured as secure in the secure part registers, only the Secure world can reprogram the corresponding IO. It is not possible to reconfigure a secure IO by modifying the non-secure part registers as long as this IO is set as secure.

Interrupts related to events on secure IOs are transmitted on secure lines (ID_PIO*_SINT). Non-secure IO events are transmitted on non-secure interrupt lines (ID_PIO*). The GIC must be configured in order to associate the secure interrupt lines to the secure interrupts group.

Table 8-10. PIO Controller Security Settings

Peripheral ID	Type	Security
ID_PIOA	User interface interrupt ID	Secure except the first 4 Kbytes (Non-secure). The interrupt targets Non-secure world [(1)].
ID_PIOB	Interrupt ID only	Non-secure
ID_PIOC	Interrupt ID only	Non-secure
ID_PIOD	Interrupt ID only	Non-secure
ID_PIOE	Interrupt ID only	Non-secure
ID_PIOA_SINT	Interrupt ID only	Secure
ID_PIOB_SINT	Interrupt ID only	Secure
ID_PIOC_SINT	Interrupt ID only	Secure
ID_PIOD_SINT	Interrupt ID only	Secure
ID_PIOE_SINT	Interrupt ID only	Secure

Note: The ID_PIOA security bit value is 'secure', whereas the corresponding interrupt ID_PIOA is dedicated to the Non-secure world. ID_PIOA must be secure so that the PIO memory map is secure above 4 Kbytes (a mechanism implemented in HBridge). The security bit value of peripheral IDs can conflict with the security level of interrupt IDs. In such case, the peripheral security level always prevails.

Refer to the section Parallel Input/Output Controller (PIO) for more details.

8.4.7 TrustZone AES Bridge Address Space Controller (TZAESBASC)

8.4.7.1 Function

The TrustZone AES Bridge (TZAESB) performs encrypted memory accesses. It also offers the possibility for Secure and Non-secure worlds to perform encrypted memory accesses with different encryption keys. The memory space that can be encrypted by TZAESB include the NFC_RAM, EBI, SRAM, QSPI and DDR spaces.

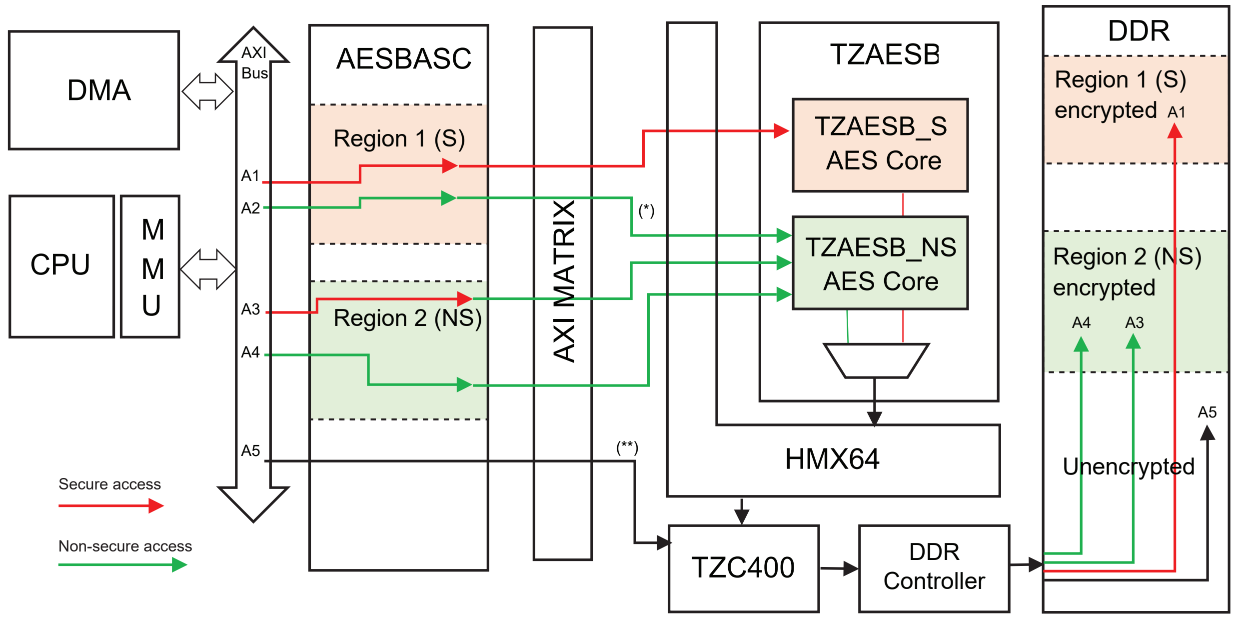
In order to use the TZAESB (for on-the-fly encrypted accesses), the TrustZone AES Bridge Address Space Controller (TZAESBASC) must be configured. This block defines the regions in the memory map where encryption is needed, and their security level. Whenever the address of a memory access matches a region defined in TZAESBASC, the access is routed through the TZAESB instead of taking the direct unencrypted path.

When access is performed to a region configured as non-secure in TZAESBASC, the protection bit is modified on-the-fly as non-secure even if the access was initially marked as secure. The access is then routed to the non-secure AES core in TZAESB (as illustrated with access A3 in the following figure).

TZAESBASC, MATRIX and TZC400 security settings must match.

The following schematic illustrates the behavior of the TZAESB when ID_TZAESB_S is secure and ID_TZAESB_NS is non-secure. This example shows five accesses (A1, A2, A3, A4, A5) coming either from the processor or the DMA with different securities, and targeting region 1 (secure), region 2 (non-secure) and a clear region (i.e., not defined in TZAESB) in the DDR space.

Figure 8-4. Example of Security Management with Different Access Types



Non-secure access A2 to region 1 (secure) is not immediately denied. The access is stopped when reaching TZC400, leading to a bus error with corresponding denied access information, due to TZC400 and TZAESBASC identical security settings.

Secure access A3 becomes non-secure when crossing TZAESBASC, leading TZAESB to select the non-secure AES core in order to use the correct encryption key. This access is not denied by TZC400 because the target address is a non-secure region.

When the application does not require two different encryption keys, the encrypted access bandwidth can be increased by running the two cores in parallel when two different hosts from different matrixes access TZAESB, for example DMAC0 and DMAC2. To do so, the user must program the same security bit values (ID_TZAESB_S or ID_TZAESB_NS) and use identical encryption keys for both cores.

8.4.7.2 Encryption Behavior

ID_TZAESB_S Security Bit Setting in TZPM	ID_TZAESB_NS Security Bit Setting in TZPM	Non-Secure Access to TZAESB_S User Interface	Non-Secure Access to TZAESB_NS User Interface	Non-Secure Memory Access through TZAESB	Secure Memory Access through TZAESB	Encryption Behavior
Secure	Non-secure	Denied	Accepted	Accepted; taking non-secure path; accesses to secure regions will be denied by TZC400	Accepted; only the accesses to secure regions take secure path	Secure regions encrypted with TZAESB_S key; non-secure regions encrypted with TZAESB_NS key Secure world can decrypt regions encrypted by Non-secure world even if keys differ.
Secure	Secure	Denied	Denied	Denied (response error)	Accepted only when targeting secure region[1]	Secure regions encrypted with improved bandwidth (TZAESB_S and TZAESB_NS keys must match)

...........continued

ID_TZAESB_S Security Bit Setting in TZPM	ID_TZAESB_NS Security Bit Setting in TZPM	Non-Secure Access to TZAESB_S User Interface	Non-Secure Access to TZAESB_NS User Interface	Non-Secure Memory Access through TZAESB	Secure Memory Access through TZAESB	Encryption Behavior
Non-secure	Non-secure	Accepted	Accepted	Accepted	Accepted	All regions encrypted with improved bandwidth (TZAESB_S and TZAESB_NS keys must match); Secure world can decrypt regions encrypted by Non-secure world as keys match.
Non-secure	Secure	NA	NA	NA	NA	Forbidden mode (not programmable)

Note:
1. Because the TZAESBASC converts secure accesses to non-secure accesses when the target address is in a non-secure region, the TZAESB denies the access if both security bits are secure.

8.4.7.3 Access Denials

ID_TZAESB_S Security Bit Setting in TZPM	ID_TZAESB_NS Security Bit Setting in TZPM	R/W Access to Secure Region from Non-Secure World	Bufferable Access (using MMU)	Data Abort	MATRIX Interrupt	TZC400 Interrupt
Secure	Non-secure	Read	–	Yes / No	Yes	Yes
		Write	No	Yes / No	Yes	Yes
			Yes	Yes / No	Yes(2) / No	Yes
Secure	Secure	Read	–	Yes	Yes	No(1)
		Write	No	Yes	Yes	No(1)
			Yes	Yes	Yes(2)	No(1)
Non-secure	Non-secure	Read	–	Yes / No	Yes	Yes
		Write	No	Yes / No	Yes	Yes
			Yes	Yes / No	Yes(2) / No	Yes

Notes:
1. Access denied by TZAESB, not propagated to TZC400.
2. In the case of write burst accesses, MATRIX_MEARx registers might not return the address corresponding to the offending access: due to the AXI protocol, the TZC400 response error indicates the last accessed address (not which of the consecutive accesses failed during the burst).

Peripheral ID	Type	Security
ID_AESBASC	User interface	Secure
ID_TZAESB_NS	User interface	Programmable Secure
ID_TZAESB_NS_INT	Interrupt ID only	Secure
ID_TZAESB_S	User interface	Programmable Secure
ID_TZAESB_S_INT	Interrupt ID only	Secure

Refer to the section TrustZone AESB Address Space Controller (TZAESBASC) for more details.

8.4.7.4 NAND Flash

NAND Flash pages can be accessed with TZAESB. ECC sections are not encrypted. With page sizes ≤ 4 Kbytes, use only bank 0 in NFC_RAM.

8.4.8 TrustZone Watchdog

8.4.8.1 Function

The lower 4 Kbytes of the user interface memory map are never secure and are dedicated to the Non-Secure Watchdog (NS_WDT). Above this offset, the user interface is dedicated to the Always Secure Watchdog (PS_WDT).

The TrustZone Watchdog offers a dedicated watchdog to both secure and non-secure worlds.

The TrustZone Watchdog offers a security escalation process based on transmitting interrupts before generating alarms or system reset.

Peripheral ID	Type	Security
ID_DWDT_S	User interface Interrupt ID	Secure (except the first 4 Kbytes)
ID_DWDT_NS	Interrupt ID only	Non-secure
ID_DWDT_ALARM	Interrupt ID only	Secure

Refer to the section Dual Watchdog Timer (DWDT) for more details.

8.4.8.2 Basic Programming Guidelines

The Configure Watchdog period is the time for a watchdog to generate an alarm or a system reset from the last counter reload. Note that watchdogs count on slow_clock/128, so the period step is about 4 ms.

The Configure Watchdog Interrupt level is the time for a watchdog to generate a “force” interrupt from the last counter reload. This time is necessarily shorter than the watchdog period. The interrupt level step is the same as the period step.

There are two PIT counters, one secure and one non-secure. These counters must be configured in a Continuous Interrupt mode, with a period shorter than the watchdog interrupt level. Note that PITs count on the system clock, so the step depends on the selected clock scheme.

PS_WDT must be configured to generate a reset or not when the counter underflows.

Security module TZWDT protection must be configured to erase or not the secure RAM in case of PS_WDT counter underflow.

PS_WDT and NS_WDT level interrupts (“force” interrupts) must be configured.

After a watchdog system reset, RSTC_SR can be read to get the watchdog reset flag. This register must be read before the watchdog reset event, since it only reports the reset event following the last read.

8.4.9 Security Module (SECUMOD)

SECUMOD_GPSBR is dedicated to control SECUMOD-related analog objects used for alarms or backup supply safety:

- Enable/disable backup power switch (PWSBU) switching to VBAT on a SECUMOD autobackup event
- Selection of VDDCPU supply monitor (SMCPU) range (depending on the processor frequency mode)
- Selection of temperature monitor (TEMPMON) high alarm threshold (105°C/120°C typ)
- Selection of external interrupts EXT_IRQ0/EXT_IRQ1 for Automatic Backup mode protocol

Two independent peripheral IDs are available for either SECUMOD or SECURAM.

Peripheral ID	Type	Security
ID_SECUMOD	User interface interrupt	Always Secure
ID_SECURAM	Interrupt only	Always Secure

Refer to the section Security Module (SECUMOD) for more details.

8.4.10 Extended DMA Controller (XDMAC)

Security of DMA channels is configurable channel-by-channel using bit PROT in the XDMAC_CC register. This bit can be configured in the Secure world only. A channel is non-secure by default.

Interrupts related to secure DMA channels are routed on a secure interrupt line.

Peripheral ID	Type	Security
ID_XDMAC0	User interface interrupt	Programmable Secure
ID_XDMAC0_SINT	Interrupt only (Secure channel)	Secure
ID_XDMAC1	User interface interrupt	Programmable Secure
ID_XDMAC1_SINT	Interrupt only (Secure channel)	Secure
ID_XDMAC2	User interface interrupt	Programmable Secure
ID_XDMAC2_SINT	Interrupt only (Secure channel)	Secure

Refer to the section DMA Controller (XDMAC) for more details.

8.5 Peripheral Clocks and Security

Table 8-11. Peripheral Identifiers

Instance ID	Instance Name	Security	TZ Security Management	GIC SPI Interrupt	External Interrupt	PMC Clock Control	Main System Bus Clock	Max Generic Clock Freq. (MHz)	SYSPLLCK	DDRPLLCK	IMGPLLCK	BAUDPLLCK	AUDIOPLLCK	ETHPLLCK	Instance Description

⚠WARNING

1. GCLK must be started before accessing registers.

Note:

1. Select GCLK input as MD_SLCK or TD_SLCK.

9. Cortex-A7 Processor (Arm)

9.1 Description

The high-performance, low-power Arm Cortex-A7 processor features an L1 cache subsystem that provides full virtual memory capabilities. The Cortex-A7 processor implements the Arm v7-A architecture and runs 32-bit Arm instructions, and 16-bit and 32-bit Thumb instructions.

The Cortex-A7 NEON Media Processing Engine (MPE) extends the Cortex-A7 functionality to provide support for the Arm v7 Advanced SIMD v2 and Vector Floating-Point v4 (VFPv4) instruction sets. The Cortex-A7 NEON MPE provides flexible and powerful acceleration for signal processing algorithms including multimedia such as image processing, video decode/encode, 2D/3D graphics, and audio. For details, refer to the Cortex-A7 NEON Media Processing Engine Technical Reference Manual.

The Cortex-A7 processor includes TrustZone technology to enhance security by partitioning the SoC's hardware and software resources in a Secure world for the security subsystem and a Normal world for the rest, enabling a strong security perimeter to be built between the two. For details, refer to Security Extensions Overview in the Cortex-A7 Technical Reference Manual. Refer to the Arm Architecture Reference Manual, Arm v7-A and Arm v7-R edition for details on how TrustZone works in the architecture.

The Cortex-A7 core, the Floating Point Unit (FPU) and NEON Media Processing Engine (MPE) are based on Arm Ltd. r0p5 and are highly configurable at the hardware design stage. These configurations are described in the sections that follow. The default software configuration has been intensively tested and leads to best results in any conditions.

9.1.1 Reference Documents

Document Title	Available
Cortex-A7 Core Technical Reference Manual	developer.arm.com/
Cortex-A7 Floating-Point Unit Technical Reference Manual	
Cortex-A7 NEON Media Processing Engine Technical Reference Manual	
Arm Architecture Reference Manual Arm v7-A and Arm v7-R edition	
Coresight 400 Technical Reference Manual	

9.2 Embedded Characteristics

The Cortex-A7 processor (r0p5) implements the Arm v7-A architecture. This includes:

- 32-bit Arm Instruction Set
- Thumb Instruction Set featuring 16-bit and 32-bit Instructions
- ThumbEE Instruction Set
- Implementation of the Jazelle Extension
- Arm v7 Debug Architecture
- TrustZone Security Extensions
- Harvard Level 1 Memory System with a Memory Management Unit (MMU)
- 32 Kbytes L1 Data Cache
- 32 Kbytes L1 Instruction Cache
- 256 Kbytes L2 Cache
- Generic Interrupt Controller (GIC)
- Media Processing Engine (MPE) with NEON Technology
- Trace Support through an Embedded Trace Macrocell (ETM) Interface

- Performance Monitoring Unit (PMU)

9.3 Clocks

CPUPLLCK, comprising the L2 cache controller and L2 cache memory, feeds the Cortex-A7 processor, the L1 cache, the NEON MPE, the ETM and the GIC.

CPUPLLCK is divided (MCK0) to feed the rest of the core subsystem and the CSS AXI matrix.

The L2 cache controller runs at CPU frequency. The L2 cache memories run at one half of the CPU clock frequency.

The CPU frequency can be adapted to the application requirements with frequency and voltage scaling, including power saving, in case high performance is not required. Refer to VDDCPU characteristics in the section Electrical Characteristics for more details.

To optimize performance, a path dedicated to high frequency exists between the CPU and UDDRC. It is clocked by MCK4. Refer to the section System Interconnect and Security (SIS) for more details.

9.4 Power Supplies

The Cortex-A7 processor, including L1 and L2 caches, is powered with dedicated VDDCPU power rails, while the rest of the core system is powered with VDDCORE.

By separating the power supplies, power consumption can be reduced when the core is not active by powering off the VDDCPU section. Refer to ULP2 Low Power Mode in the section Electrical Characteristics for more details.

The CPU power supply can be adapted to the requirements with power scaling in case high performance is required. Refer to VDDCPU characteristics in the section Electrical Characteristics for more details.

9.5 Generic Interrupt Controller (GIC)

The integrated Generic Interrupt Controller (GIC) collates and arbitrates from a large number of interrupt sources. It provides:

- Masking of interrupts
- Prioritization of interrupts
- Distribution of the interrupts to the target processors
- Tracking the status of interrupts
- Generation of interrupts by software
- Support for security extensions
- Support for virtualization extensions

Refer to the Cortex-A7 Core Technical Reference Manual for more information about the GIC.

9.6 Media Processing Engine (MPE) with NEON Technology

The Cortex-A7 NEON Media Processing Engine (MPE) extends the Cortex-A7 functionality to provide support for the Arm v7 Advanced SIMDv2 and Vector Floating-Pointv4 (VFPv4) instruction sets. The Cortex-A7 NEON MPE supports all addressing modes and data-processing operations described in the Arm Architecture Reference Manual, Arm v7-A and Arm v7-R edition.

The Cortex-A7 NEON MPE includes the following features:

- SIMD and scalar single-precision floating-point computation
- Scalar double-precision floating-point computation
- SIMD and scalar half-precision floating-point conversion
- SIMD 8, 16, 32, and 64-bit signed and unsigned integer computation
- 8 or 16-bit polynomial computation for single-bit coefficients

- Structured data load capabilities
- Large, shared register file, addressable as:
  - Thirty-two 32-bit S (single) registers
  - Thirty-two 64-bit D (double) registers
  - Sixteen 128-bit Q (quad) registers

See the Arm Architecture Reference Manual, Arm v7-A and Arm v7-R edition for more information about the extension register set.

The operations include:

- Addition and subtraction
- Multiplication with optional accumulation
- Maximum or minimum value driven lane selection operations
- Inverse square-root approximation
- Comprehensive data-structure load instructions, including register-bank-resident tablelookup

See the Cortex-A7 NEON Media Processing Engine Technical Reference Manual for details of the NEON extensions.

9.7 Debug

Refer to the section Debug and Test for full details.

9.8 Performance Monitoring Unit (PMU)

The processor features a Performance Monitoring Unit (PMU), made up of logic to gather various statistics on the operation of the processor and memory system during runtime, based on the PMUv2 architecture. These events provide useful information about the behavior of the processor that can be used when debugging or profiling code.

The PMU provides four counters. Each counter can count any of the events available in the processor.

Refer to the Cortex-A7 Core Technical Reference Manual for details on the PMU extensions.

9.9 Timestamp Generator

The Arm ID (GCLK29) is the source clock for the timestamp generator. It is running and is configured to use MAINCK with no divider at reset.

The Coresight 400 IP is memory-mapped into APB_DEBUG_S (0xE8800000) and the timestamp registers are at an offset of 0x43000.

To generate timestamps:

1. , access the memory map interface of the coresight timestamp module[(1)] and:
   a. Set the timestamp generator frequency value to 24 MHz by writing 24000000 to the CNTFID0 register (same as the MAINCK frequency).
   b. Enable the timestamp generator by writing 1 to the CNTCR register.
2. Enable PPI interrupt ID 29 in GIC (secure physical timer interrupt)[(2)].
3. Access the generic timer coprocessor interface (CP15)[(3)] to:
   a. Set the counter frequency value to 24 MHz in the CNTFRQ register.
   b. Set the timer count value in the CNTP_TVAL register.
   c. Enable the Timer event by writing into the CNTP_CTL register.

When the timer expires, a PPI interrupt is generated with interrupt ID 29.

Notes:

1. Refer to Arm V7A, ARCH Manual (DDI0406C), Appendix D5.2, Coresight 400 TRM (DDI0480G), Section 3.19.
2. Refer to Cortex-A7 TRM (DDI0464F), Section 8.2.2.
3. Refer to Arm V7A, ARCH Manual (DDI0406C), B8.2.

10. External Interrupt Controller (EIC)

10.1 Description

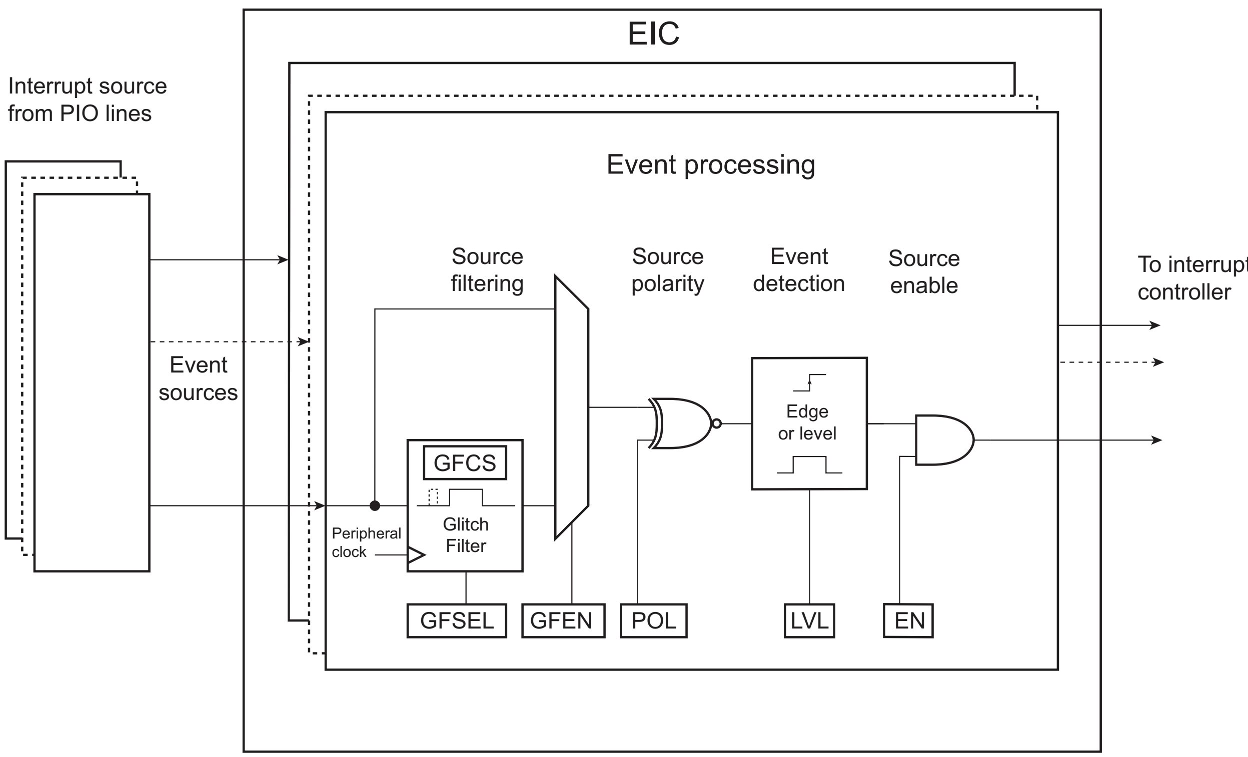
The External Interrupt Controller (EIC) forwards external interrupt sources from two PIO lines to the interrupt controller by providing some pre-processing capabilities (filtering, polarity inversion, edge detection, enable).

10.2 Embedded Characteristics

- Glitch Filter
- Programmable Source Polarity
- Edge or Level Detection
- Freeze Capability for Each Interrupt Line Configuration
- Global Configuration Write Protection Register with Key

10.3 Block Diagram

Figure 10-1. EIC Block Diagram



10.4 I/O Lines Description

Pin Name	Pin Description	Type
EIC_EIS0–EIC_EIS1	External Interrupt Source 0–External Interrupt Source 1	Input

10.5 Product Dependencies

10.5.1 I/O Lines

The external interrupt signals EIC_EIS0..EIC_EIS1 are multiplexed through the PIO controller(s).

Depending on the features of the PIO controller used in the product, the pins must be programmed in accordance with their assigned interrupt function.

10.5.2 Power Management

The EIC is continuously clocked. The Power Management Controller has no effect on the EIC behavior.

10.5.3 External Interrupt Sources

The following table describes the external interrupt sources available in the product.

Source Number	Source Name	Source Description
0	EIC_EIS0	External Interrupt Source
1	EIC_EIS1	External Interrupt Source

10.6 Functional Description

10.6.1 Interrupt Line Characteristics

For each event source, the EIC features a dedicated interrupt line as shown in the Block Diagram.

If Glitch Filter Enable (GFEN) is cleared in the Source Configuration register (EIC_SCFGxR), pulses of any width can be forwarded and detected as valid source events on the interrupt line x regardless of the respective frequencies of the source clock, the EIC peripheral clock and the Interrupt Controller clock.

If EIC_SCFGxR.GFEN is set, the source events are filtered to remove unwanted glitches. The glitch filter forwards its input level when it is maintained for more than 2^{GFSEL} peripheral clock cycles and rejects pulses narrower than 2^{GFSEL}-1 peripheral clock cycles.

The source event polarity can be changed by EIC_SCFGxR.POL.

Either edge or level event detection can be performed by EIC_SCFGxR.LVL.

When set, EIC_SCFGxR.FRZ freezes all interrupt line settings until hardware reset. This includes the settings in EIC_SCFGxR. This feature can be used to prevent any corruption of the critical interrupt lines configuration.

If the glitch filter is enabled in EIC_SCFGxR.GFEN, the maximum propagation delay through the EIC (see the following figure) is calculated as:

$$\mathrm{EIC\_delay\_max} = (2 + 2\mathrm{GFSEL}) * \mathrm{periph\_clk\_period} + 2.5 * \mathrm{clock\_period}$$

and the minimum propagation delay through the EIC is:

$$\mathrm{EIC\_delay\_min} = (1 + 2\mathrm{GFSEL}) * \mathrm{periph\_clk\_period} + 1 * \mathrm{clock\_period}$$

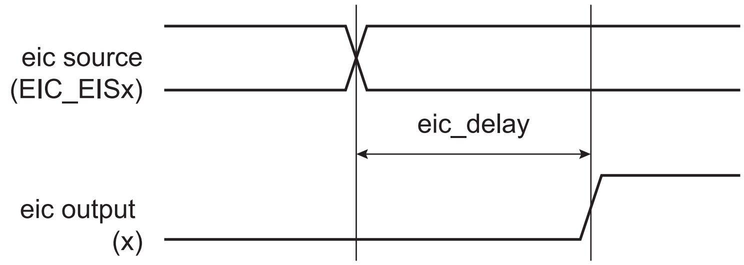
If the glitch filter is disabled, the maximum propagation delay through the EIC is calculated as:

$$\mathrm{EIC\_delay\_max} = 2.5 * \mathrm{clock\_period}$$

and the minimum propagation delay through the EIC is:

$$\mathrm{EIC\_delay\_min} = 1 * \mathrm{clock\_period}$$

Figure 10-2. EIC Propagation Delay



clock_period is the peripheral clock period of the EIC as programmed in the Power Management Controller.

10.6.2 External Interrupt Line Programming

The steps to set up or change the external interrupt line x configuration are the following:

1. Clear SCFGxR.EN to disable the EIC interrupt source.
2. Perform any external setup that might be required at the source peripheral and wait until the peripheral source output is stabilized.
3. If the glitch filter is enabled on the interrupt line, wait until the Ready flag RDYx is set in the Glitch Filter Configuration Status register (EIC_GFCS).
4. Write the required interrupt line configuration fields among GFSEL, GFEN, POL, LVL into EIC_SCFGxR.
5. If the glitch filter is enabled on the interrupt line, wait until EIC_GFCS.RDYx is set.
6. Set EIC_SCFGxR.EN if the source is not yet enabled and, if required for safety, freeze the interrupt line x configuration by setting EIC_SCFGxR.FRZ.

Example:

If the user desires to stop or minimize the circuit activity after a voltage or frequency failure detection on a rising edge of an EIC interrupt source, the polarity can be changed with a single write to EIC_SCFGxR.POL to detect a falling edge of the same source. Detection of the falling edge source indicates the recovery of a normal condition. In this case, the steps described previously can be ignored.

10.6.3 Register Write Protection

To prevent any single software error from corrupting EIC behavior, certain registers in the address space can be write-protected.

The following register can be write-protected by setting WPCFEN in the Write Protection Mode register (EIC_WPMR):

- External Interrupt Controller Source Configuration register x (EIC_SCFGxR)

If a write access to a write-protected register is detected, the WPVS flag in the Write Protection Status register (EIC_WPSR) is set and WVSRC indicates the register in which the write access was attempted.

WPVS is automatically cleared after reading EIC_WPSR.

If a write attempts to modify the settings of an interrupt line x that was previously frozen by setting EIC_SCFGxR.FRZ, the FZWVS flag in EIC_WPSR is set and WVSRC indicates the register in which the write access was attempted.

FZWVS is automatically cleared after reading EIC_WPSR.

If a write attempts to modify the settings of the glitch filter of interrupt line x but the Source Configuration register x (EIC_SCFGxR) access is discarded due to an already ongoing glitch filter configuration, the FZWVS flag in EIC_WPSR is set and WVSRC indicates the register in which the write access was attempted.

FZWVS is automatically cleared after reading EIC_WPSR.

10.7 Register Summary

Offset	Name	Bit Pos.	7	6	5	4	3	2	1	0
0x00	EIC_GFCS	31:24

10.7.1 EIC Glitch Filter Configuration Status Register

Name: EIC_GFCS
Offset: 0x00
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
							RDY1	RDY0
Access							R	R
Reset							0	0

Bits 0, 1 – RDYx Filter x Configuration Ready

Value	Description
0	The interrupt line x glitch filter is not yet ready for use due to a previous write to EIC_SCFGxR, or the glitch filter is not implemented for this interrupt line. The glitch filter must not be reprogrammed in EIC_SCFGxR.
1	The interrupt line x glitch filter configuration is done and the glitch filter is active. The glitch filter can be programmed in EIC_SCFGxR.

10.7.2 EIC Source Configuration Register x

Name: EIC_SCFGxR
Offset: 0x04 + x*0x04 [x=0..1]
Reset: 0x00000000
Property: Read/Write

This register can only be written if WPCFEN is cleared in the EIC Write Protection Mode register.

Bit	31	30	29	28	27	26	25	24
	FRZ							
Access	R/W							
Reset	0							

Bit	23	22	21	20	19	18	17	16
								EN
Access								R/W
Reset								0

Bit	15	14	13	12	11	10	9	8
							LVL	POL
Access							R/W	R/W
Reset							0	0

Bit	7	6	5	4	3	2	1	0
				GFEN			GFSEL[1:0]	
Access				R/W			R/W	R/W
Reset				0			0	0

Bit 31 – FRZ Interrupt Line Freeze

Value	Description
0	No effect.
1	EIC_SCFGxR is frozen until hardware reset.

Bit 16 – EN Source Enable

Value	Description
0	The EIC source x is disabled. Any source edge or level detection is discarded.
1	The EIC source x is enabled.

Bit 9 – LVL Level Detection

Value	Description
0	The EIC source x interrupt status is set on a valid source edge.
1	The EIC source x interrupt status is set on a valid source level.

Bit 8 – POL Polarity

Value	Description
0	The EIC source x is active low if LVL is set, or active on falling edge if LVL is cleared.
1	The EIC source x is active high if LVL is set, or active on rising edge if LVL is cleared.

Bit 4 – GFEN Glitch Filter Enable

Value	Description
0	The glitch filter is disabled or not implemented for EIC source x. Any source x change is forwarded as is to the source detection logic.
1	The glitch filter is enabled for EIC source x. The EIC source x glitches are filtered according to Interrupt Line Characteristics.

Bits 1:0 – GFSEL[1:0] Glitch Filter Selector
If GFEN is set, EIC source x glitches are filtered according to Interrupt Line Characteristics.

10.7.3 EIC Write Protection Mode Register

Name: EIC_WPMR
Offset: 0xE4
Reset: 0x00000000
Property: Read/Write

See Register Write Protection for the list of registers that can be write-protected.

Bit	31	30	29	28	27	26	25	24
	WPKEY[23:16]							
Access	W	W	W	W	W	W	W	W

Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**
	WPKEY[7:0]							
Access	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0
Bit	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
								WPCFEN
Access								R/W
Reset								0

Bits 31:8 – WPKEY[23:0] Write Protection Key

Value	Name	Description
0x454943	PASSWD	Writing any other value in this field aborts the write operation of the WPCFEN bit. Always reads as 0.

Bit 0 – WPCFEN Write Protection Configuration Enable

Value	Description
0	Disables the write protection on the Configuration registers if WPKEY corresponds to 0x454943 (“EIC” in ASCII).
1	Enables the write protection on the Configuration registers if WPKEY corresponds to 0x454943 (“EIC” in ASCII).

10.7.4 EIC Write Protection Status Register

Name: EIC_WPSR
Offset: 0xE8
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
	WVSRC[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
						BSWVS	FZWVS	WPVS
Access						R	R	R
Reset						0	0	0

Bits 15:8 – WVSRC[7:0] Write Violation Source
When either WPVS, FZWVS or BSWVS is set to 1, WVSRC indicates the register address offset at which a write access has been attempted.

Bit 2 – BSWVS Busy Register Write Violation Status

Value	Description
0	No write access violation of a busy register has occurred since the last read of EIC_WPSR.
1	A write access violation of a busy register has occurred since the last read of EIC_WPSR. The associated violation is reported into WVSRC.

Bit 1 – FZWVS Frozen Register Write Violation Status

Value	Description
0	No write access violation of a frozen register has occurred since the last read of EIC_WPSR.
1	A write access violation of a frozen register has occurred since the last read of EIC_WPSR. The associated violation is reported into WVSRC.

Bit 0 – WPVS Write Protection Register Violation Status

Value	Description
0	No write protection violation has occurred since the last read of EIC_WPSR.
1	A write protection violation has occurred since the last read of EIC_WPSR. The associated violation is reported into WVSRC.

11. Debug and Test

11.1 Description

The product features a number of complementary debug and test capabilities.

A common JTAG/ICE (In-Circuit Emulator) port is used for standard debugging functions, such as downloading code and single-stepping through programs.

A 2-pin debug port Serial Wire Debug (SWD) is provided in addition to the 5-pin JTAG port. The SWD provides an easy and risk-free alternative to JTAG as the two signals, SWDIO and SWCLK, are overlaid on the TMS and TCK pins, allowing for bi-modal devices that provide the other JTAG signals. These extra JTAG pins can be switched to other uses when in SWD mode.

A set of debug and test input/output pins gives direct access to these capabilities from a PC-based test environment.

11.1.1 Reference Documents

The Cortex-A7 core is based on Arm Ltd. r0p5 and is highly configurable at the hardware design stage. These configurations are described in the sections that follow.

Document Title	Available
Cortex-A7 Core Technical Reference Manual	developer.arm.com/
Arm Architecture Reference Manual Arm v7-A and Arm v7-R edition	

11.2 Embedded Characteristics

- Cortex-A7 Processor In the Loop (PIL)
  - Cortex-A7 uniprocessor
  - ETM-A7 (Trace Macrocell)
  - CTI (Cross-Triggering Interface) module
  - CTM (Cross-Triggering Matrix) module
  - APB subsystem
  - ROM table (processor ROM table)
- CSSYS Block (Debug and Trace Subsystem from SoC-400)
  - DAP with an asynchronous bridge to allow DAP/CPU asynchronous clock
  - CXAPBIC APB interconnect containing the top-level ROM table
  - ETB (Embedded Trace Buffer + 16-Kbyte ETB RAM)
  - Timestamp generation component
  - ECT (Embedded Cross-Triggering) component
- Chip ID Register
- IEEE 1149.1 JTAG Boundary-scan on All Digital Pins

11.3 Block Diagram

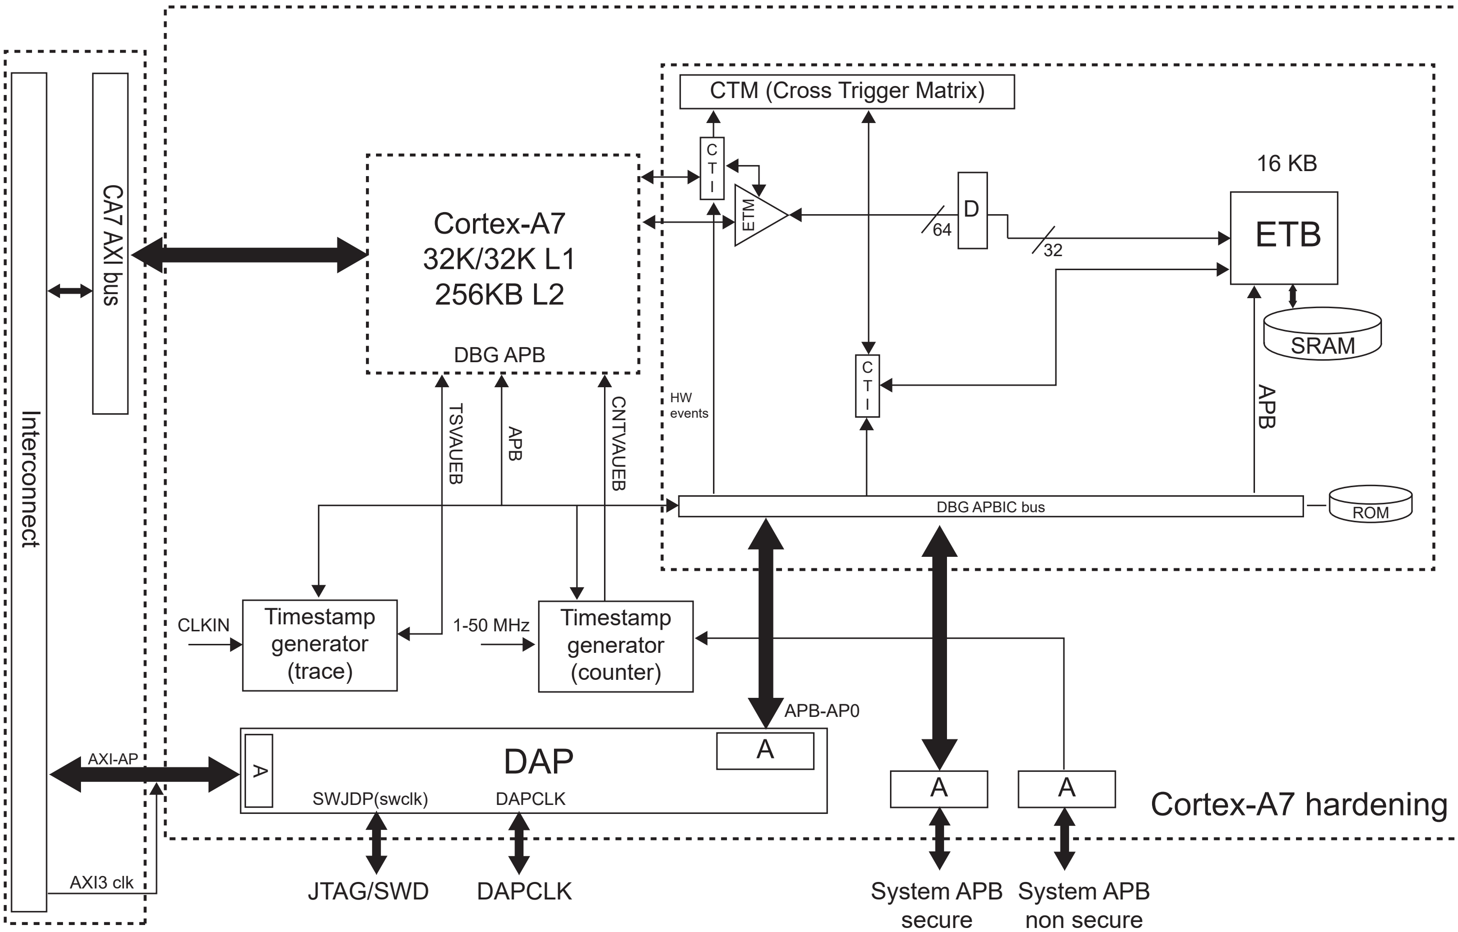

Figure 11-2. Debug and Test Interface Block Diagram

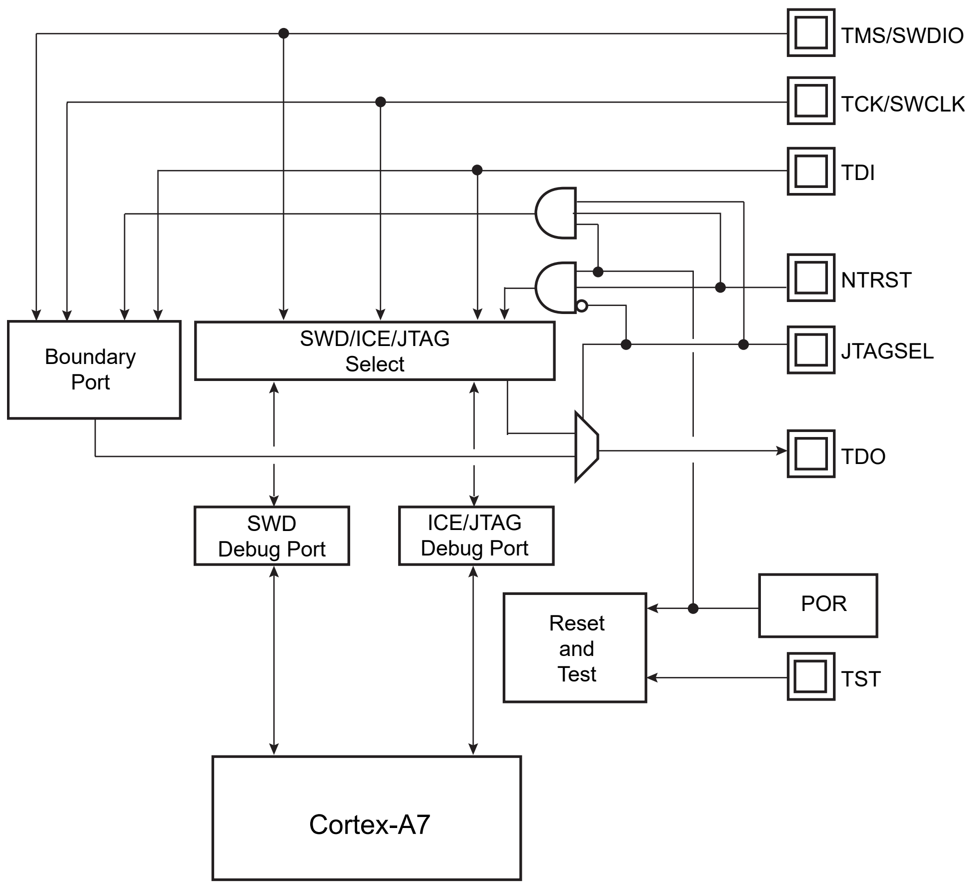

11.4 Pin Description

Table 11-1. Debug and Test Pin List

Pin Name	Function	Type	Active Level
Reset/Test			
TST	Test Mode Select	Input	–
NTRST	Test Reset Signal	Input	–
ICE and JTAG			
TCK/SWCLK	Test Clock/Serial Wire Clock	Input	–
TDI	Test Data In	Input	–
TDO	Test Data Out	Output	–
TMS/SWDIO	Test Mode Select/Serial Wire Input/Output	Input/Output	–
JTAGSEL	JTAG Selection	Input	–

11.5 Functional Description

11.5.1 Test Pin

One dedicated pin, TST, is used to define the device operating mode. The user must make sure that this pin is tied at low level to ensure normal operating conditions. Other values associated with this pin are reserved for manufacturing test.

11.5.2 EmbeddedICE™

The Cortex-A7 EmbeddedICE-RT™ is supported via the ICE/JTAG port. It is connected to a host computer via an ICE interface.The internal state of the Cortex-A7 is examined through an ICE/JTAG port which allows instructions to be serially inserted into the pipeline of the core without using the external data bus. Therefore, when in debug state, a store-multiple (STM) can be inserted into the instruction pipeline. This exports the contents of the Cortex-A7 registers. This data can be serially shifted out without affecting the rest of the system.

There are two scan chains inside the Cortex-A7 processor which support testing, debugging, and programming of the EmbeddedICE-RT. The scan chains are controlled by the ICE/JTAG port.

EmbeddedICE mode is selected when JTAGSEL is low. It is not possible to switch directly between ICE and JTAG operations. A chip reset must be performed after JTAGSEL is changed.

For further details on the EmbeddedICE, refer to the Arm document Cortex-A7 Technical Reference Manual (DDI 0464).

11.5.3 JTAG Signal Description

TMS is the Test Mode Select input which controls the transitions of the test interface state machine.

TDI is the Test Data Input line which supplies the data to the JTAG registers (Boundary Scan Register, Instruction Register, or other data registers).

TDO is the Test Data Output line which is used to serially output the data from the JTAG registers to the equipment controlling the test. It carries the sampled values from the boundary scan chain (or other JTAG registers) and propagates them to the next chip in the serial test circuit.

NTRST (optional in IEEE Standard 1149.1) is a Test-ReSeT input which is mandatory in Arm cores and used to reset the debug logic. On Cortex-A7-based cores, NTRST is a Power-on Reset output. It is asserted on power-on. If necessary, the user can also reset the debug logic with the NTRST pin assertion during 2.5 MCK periods.

TCK is the Test ClocK input which enables the test interface. TCK is pulsed by the equipment controlling the test and not by the tested device. It can be pulsed at any frequency.

11.5.4 Chip Access Using JTAG Connection

The JTAG connection is not enabled by default on this chip at delivery due to the secure ROM code implementation.

By default, the device boots in Standard mode and not in Secure mode. When the secure ROM code starts, it disables the JTAG access for the entire boot sequence.

If the secure ROM code does not find any program in the external memory, it enables the USB connection and the serial port and waits for a dedicated command to switch the chip into Secure mode.

If any other character is received, the secure ROM code starts the standard SAM-BA® monitor, locks access to the ROM memory, and enables the JTAG.

The chip can then be accessed using the JTAG connection.

If the secure ROM code finds a bootable program, it automatically disables ROM access and enables the JTAG connection just before launching the program.

The procedure to enable JTAG access is as follows:

- Connect your computer to the board with JTAG and USB (J20 USB-A).
- Power on the chip.
- Open a terminal console (TeraTerm, HyperTerminal, etc.) on your computer and connect to the USB CDC serial COM port.

- Send the '#' character. You will see then the prompt '>' character sent by the device (indicating that the standard SAM-BA Monitor is running).
- Use the Standard SAM-BA Monitor to connect to the chip with JTAG.

Note that it is not necessary to follow this sequence to connect the standard SAM-BA monitor with USB.

11.5.5 IEEE 1149.1 JTAG Boundary Scan

IEEE 1149.1 JTAG Boundary Scan allows pin-level access independent of the device packaging technology.

IEEE 1149.1 JTAG Boundary Scan is enabled when JTAGSEL is high. The SAMPLE, EXTEST and BYPASS functions are implemented. In ICE debug mode, the Arm processor responds with a non-JTAG chip ID that identifies the processor to the ICE system. This is not IEEE 1149.1 JTAG-compliant.

It is not possible to switch directly between JTAG and ICE operations. A chip reset must be performed after JTAGSEL is changed.

A Boundary-scan Descriptor Language (BSDL) file is provided to set up the test.

11.5.6 JTAG ID Code Register

Name: JTAG ID Code Register
Property: Read-only

JTAG ID Code value is 0x05B4203F.

Bit	31	30	29	28	27	26	25	24
	VERSION[3:0]				PART NUMBER[15:12]			
Access	R	R	R	R	R	R	R	R
Reset								

Bit	23	22	21	20	19	18	17	16
	PART NUMBER[11:4]							
Access	R	R	R	R	R	R	R	R
Reset								

Bit	15	14	13	12	11	10	9	8

Access	R	R	R	R	R	R	R	R
Reset								

Bit	7	6	5	4	3	2	1	0
	MANUFACTURER IDENTITY[6:0]							1
Access	R	R	R	R	R	R	R	R
Reset								

Bits 31:28 – VERSION[3:0] Product Version Number
Set to 0x0.

Bits 27:12 – PART NUMBER[15:0] Product Part Number
Product part number is 0x5B42.

Bits 11:1 – MANUFACTURER IDENTITY[10:0]
Set to 0x01f.

Bit 0 – 1
Required by IEEE standard 1149.1. Set to 1.

11.5.7 Cortex-A7 DP Identification Code Register IDCODE

The Identification Code register is always present on all DP implementations. It provides identification information about the Arm Debug Interface.

11.5.7.1 JTAG Debug Port (JTAG-DP)

Name: JTAG Debug Port (JTAG-DP)
Property: Read-only

Debug Port JTAG IDCODE value is 0x6BA00477.
Accessed using its own scan chain, the JTAG-DP Device ID Code Register.

Bit	31	30	29	28	27	26	25	24
	VERSION[3:0]				PART NUMBER[15:12]			
Access	R	R	R	R	R	R	R	R

Reset								

Bits 31:28 – VERSION[3:0] Product Version Number
Set to 0x0.

Bits 27:12 – PART NUMBER[15:0] Product Part Number
Product part number is 0xBA00.

Bits 11:1 – DESIGNER[10:0]
Set to 0x26B.

Bit 0 – 1
Required by IEEE Standard 1149.1. Set to 1.

11.5.7.2 Serial Wire Debug Port (SW-DP)

Name: Serial Wire Debug Port (SW-DP)
Property: Read-only

Debug Port Serial Wire IDCODE is 0x6BA02477.

At address 0x0 on read operations when the APnDP bit = 0. Access to the Identification Code Register is not affected by the value of the CTRLSEL bit in the Select register.

Bit	31	30	29	28	27	26	25	24
	VERSION[3:0]				PART NUMBER[15:12]

Bits 31:28 – VERSION[3:0] Product Version Number
Set to 0x0.

Bits 27:12 – PART NUMBER[15:0] Product Part Number
Product part number is 0xBA02.

Bits 11:1 – DESIGNER[10:0]
Set to 0x26B.

Bit 0 – 1
Required by IEEE standard 1149.1. Set to 1.

11.5.8 Debug ROM

Table 11-2. Debug ROM

Component	Address (Debugger)	Address (APB System)
Top-level ROM Table (CSSYS)	0x80000000	Base_Ad + 0x00000
ROM Table (PIL)	0x80020000	Base_Ad + 0x20000
Cortex-A7 DBG (PIL)	0x80030000	Base_Ad + 0x30000
Cortex-A7 PMU (PIL)	0x80031000	Base_Ad + 0x31000
CSCTI (PIL)	0x80038000	Base_Ad + 0x38000
ETM-A7 (PIL)	0x8003C000	Base_Ad + 0x3C000
CXETB (CSSYS)	0x80040000	Base_Ad + 0x40000

...........continued

Component	Address (Debugger)	Address (APB System)
CXCTI (CSSYS)	0x80041000	Base_Ad + 0x41000
CXTSGEN Trace (CSSYS)	0x80042000	Base_Ad + 0x42000
CXTSGEN Generic CA-7 Timer (CSSYS)	0x80043000	Base_Ad + 0x43000

12. NIC-400 Global Programmer’s View (NICGPV)

12.1 Description

The system embeds several AXI bus matrixes.

This section describes how to perform priority, arbitration, Quality of Service (QoS) and outstanding configuration settings for AXI peripherals. Refer to the section System Interconnect and Security (SIS) for the description of hosts, clients and interconnections.

12.2 Register Summary

12.2.1 AMIB Bus Matrix Issuing Functionality Modification Register

Name: NICGPV_AMIB_FN_MOD_BM_ISSx
Offset: 0x2008 + x*0x1000 [x=0..14]
Reset: 0x00000000
Property: Read/Write

This register is only present if the block is connected directly to a switch. This register sets the issuing capability of the preceding switch arbitration scheme to 1.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
							WRITE_ISS_OVERRIDE	READ_ISS_OVERRIDE
Access							R/W	R/W
Reset							0	0

Bit 1 – WRITE_ISS_OVERRIDE Write Issuing Override

Value	Description
0	No effect.
1	Write issuing capability is limited to one outstanding transaction.

Bit 0 – READ_ISS_OVERRIDE Read Issuing Override

Value	Description
0	No effect.
1	Read issuing capability is limited to one outstanding transaction.

12.2.2 ASIB Read Channel QoS Register

Name: NICGPV_ASIB_READ_QOSx
Offset: 0x042100 + x*0x1000 [x=0..10]
Reset: 0x00000000
Property: Read/Write

This register is only present when the QoS settings for an ASIB (host) are set to Programmable.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
					RD_QOS[3:0]			
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bits 3:0 – RD_QOS[3:0] Read QoS
Read channel QoS value.

12.2.3 ASIB Write Channel QoS Register

Name: NICGPV_ASIB_WRITE_QOSx
Offset: 0x042104 + x*0x1000 [x=0..10]
Reset: 0x00000000
Property: Read/Write

This register is only present when the QoS settings for an ASIB (host) are set to Programmable.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
					WR_QOS[3:0]			
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bits 3:0 – WR_QOS[3:0] Write QoS
Write channel QoS value.

12.2.4 ASIB QoS Control Register

Name: NICGPV_ASIB_QOS_CNTLx
Offset: 0x04210C + x*0x1000 [x=0..10]
Reset: 0x00000000
Property: Read/Write

This register contains the enable bits for all regulators. By default, all bits are set to 0 and no regulation is enabled.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
				MODE_AR_FC				MODE_AW_FC
Access				R/W				R/W
Reset				0				0

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
	EN_AWAR_OT	EN_AR_OT	EN_AW_OT	EN_AR_FC	EN_AW_FC	EN_AWAR_RATE	EN_AR_RATE	EN_AW_RATE
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit 20 – MODE_AR_FC AR Feedback Control Mode
Select feedback control regulation for AR of either transaction or address latency.
0 (TRANS_LAT): Transaction latency
1 (ADDR_LAT): Address latency

Bit 16 – MODE_AW_FC AW Feedback Control Mode
Select feedback control regulation for AW of either transaction or address latency.
0 (TRANS_LAT): Transaction latency
1 (ADDR_LAT): Address latency

Bit 7 – EN_AWAR_OT AWAR Outstanding Transactions Enable
0 (DISABLED): Disable combined regulation of outstanding transactions.
1 (ENABLED): Enable combined regulation of outstanding transactions.

Bit 6 – EN_AR_OT AR Outstanding Transactions Enable
0 (DISABLED): Disable regulation of outstanding read transactions.
1 (ENABLED): Enable regulation of outstanding read transactions.

Bit 5 – EN_AW_OT AW Outstanding Transactions Enable
0 (DISABLED): Disable regulation of outstanding write transactions.
1 (ENABLED): Enable regulation of outstanding write transactions.

Bit 4 – EN_AR_FC AR Feedback Control Enable
0 (DISABLED): Disable regulation of AR transaction or address latency.
1 (ENABLED): Enable regulation of AR transaction or address latency using feedback control, depending on the MODE_AR_FC setting.

Bit 3 – EN_AW_FC AW Feedback Control Enable
0 (DISABLED): Disable regulation of AW transaction or address latency.
1 (ENABLED): Enable regulation of AW transaction or address latency using feedback control, depending on the MODE_AW_FC setting.

Bit 2 – EN_AWAR_RATE AW and AR Rates Enable
0 (DISABLED): Disable combined AW and AR rate regulation.
1 (ENABLED): Enable combined AW and AR rate regulation.

Bit 1 – EN_AR_RATE AR Rate Enable
0 (DISABLED): Disable AR rate regulation.
1 (ENABLED): Enable AR rate regulation.

Bit 0 – EN_AW_RATE AW Rate Enable
0 (DISABLED): Disable AW rate regulation.
1 (ENABLED): Enable AW rate regulation.

12.2.5 ASIB Maximum Number of Outstanding Transactions Register

Name: NICGPV_ASIB_MAX_OTx
Offset: 0x042110 + x*0x1000 [x=0..10]
Reset: 0x00000000
Property: Read/Write

This register is used to program the maximum number of address requests for the AR and AW channels.

Bit	31	30	29	28	27	26	25	24
			AR_MAX_OTI[5:0]					
Access			R/W	R/W	R/W	R/W	R/W	R/W
Reset			0	0	0	0	0	0
Bit	**23**	**22**	**21**	**20**	**19**	**18**	**17**	**16**
	AR_MAX_OTF[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**
			AW_MAX_OTI[5:0]					
Access			R/W	R/W	R/W	R/W	R/W	R/W
Reset			0	0	0	0	0	0
Bit	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	AW_MAX_OTF[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 29:24 – AR_MAX_OTI[5:0] AR Maximum Outstanding Transaction Integer
Corresponds to the integer part of the maximum outstanding AR addresses.

Bits 23:16 – AR_MAX_OTF[7:0] AR Maximum Outstanding Transaction Fraction
Corresponds to the fractional part of the maximum outstanding AR addresses.

Bits 13:8 – AW_MAX_OTI[5:0] AW Maximum Outstanding Transaction Integer
Corresponds to the integer part of the maximum outstanding AW addresses.

Bits 7:0 – AW_MAX_OTF[7:0] AW Maximum Outstanding Transaction Fraction
Corresponds to the fractional part of the maximum outstanding AW addresses.

12.2.6 ASIB Maximum Combined Outstanding Transactions Register

Name: NICGPV_ASIB_MAX_COMB_OTx
Offset: 0x042114 + x*0x1000 [x=0..10]
Reset: 0x00000000
Property: Read/Write

This register is used to program the maximum number of address requests for the AR and AW channels.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
		AWAR_MAX_OTI[6:0]						
Access		R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset		0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	AWAR_MAX_OTF[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 14:8 – AWAR_MAX_OTI[6:0] AW and AR Combined Maximum Outstanding Transactions Integer
Integer part of maximum combined outstanding AW and AR addresses

Bits 7:0 – AWAR_MAX_OTF[7:0] AW and AR Combined Maximum Outstanding Transactions Fraction
Fractional part of maximum combined outstanding AW and AR addresses

12.2.7 ASIB Write Address Channel Peak Rate Register

Name: NICGPV_ASIB_AW_Px
Offset: 0x042118 + x*0x1000 [x=0..10]
Reset: 0x00000000
Property: Read/Write

This register is used to program a binary fraction of the peak number of transfers per cycle.

Bit	31	30	29	28	27	26	25	24
	AW_P[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

The register bits are active high.

Value	Name	Description
0	READ_ISS_OVERRIDE	Read issuing.
1	WRITE_ISS_OVERRIDE	Write issuing.

13. Bus Matrix (MATRIX)

13.1 Description

The system embeds one AHB bus matrix.

This section describes how to perform priority, arbitration and security settings for peripherals indicated as “MATRIX” in the table “System Interconnections”. These include memories (USB_RAM, SRAM_P0, SRAM_P1, SMC, QSPI0, QSPI1, NFC_RAM) and ISC Host.

Refer to the section System Interconnect and Security (SIS) for the description of hosts, clients and interconnections.

13.2 Embedded Characteristics

- Support for Long Bursts (32, 64, 128 and 256-bit long)
- Enhanced Programmable Mixed Arbitration for Each Client
  - Round-robin
  - Fixed priority
  - Latency Quality of Service
- Programmable Default Host for Each Client
  - No default host
  - Last accessed default host
  - Fixed default host
- Deterministic Maximum Access Latency for Hosts
- Zero or One Cycle Arbitration Latency for the First Access of a Burst
- Bus Lock Forwarding to Clients
- Host Number Forwarding to Clients
- One Special Function Register for Each Client (Not dedicated)
- Register Write Protection of User Interface Registers
- Arm TrustZone Technology

13.3 Memory Mapping

The MATRIX provides one decoder for every host interface. The decoder offers each host several memory mappings. Each memory area can be assigned to several clients. Booting at the same address while using different clients (i.e., external RAM, internal ROM or internal Flash, etc.) becomes possible.

13.4 Special Bus Granting Techniques

The MATRIX provides some speculative bus granting techniques in order to anticipate access requests from hosts. Hence, latency is reduced at first access of a burst or, for a single transfer, as long as the client is free from any other host access. It does not provide any benefit if the client is continuously accessed by more than one host, since arbitration is pipelined and has no negative effect on the client bandwidth or access latency.

This bus granting technique sets a different default host for every client.

At the end of the current access, if no other request is pending, the client remains connected to its associated default host. A client can be associated with three kinds of default hosts:

- no default host
- last access host
- fixed default host

To change from one type of default host to another, the user interface provides Client Configuration registers (MATRIX_SCFGx), one for every client, which set a default host for each client. MATRIX_SCFGx contain two fields to manage host selection: DEFMSTR_TYPE and FIXED_DEFMSTR. The 2-bit DEFMSTR_TYPE field selects the default host type (no default, last access host, fixed default host), whereas the 4-bit FIXED_DEFMSTR field selects a fixed default host provided that DEFMSTR_TYPE is set to fixed default host. Refer to section 13.11.2. MATRIX_SCFGx.

13.5 No Default Host

After the end of the current access, if no other request is pending, the client is disconnected from all hosts.

This configuration incurs one latency clock cycle for the first access of a burst after bus Idle. Arbitration without default host may be used for hosts that perform significant bursts or several transfers with no Idle cycle in-between, or if the client bus bandwidth is widely used by one or more hosts.

This configuration provides no benefit on access latency or bandwidth when reaching maximum client bus throughput whatever the number of requesting hosts.

13.6 Last Access Host

After the end of the current access, if no other request is pending, the client remains connected to the last host that performed an access request.

This enables the MATRIX to remove the one latency cycle for the last host that accessed the client. Other non-privileged hosts still get one latency clock cycle if they need to access the same client. This technique is useful for hosts that mainly perform single accesses or short bursts with some Idle cycles in-between.

This configuration provides no benefit on access latency or bandwidth when reaching maximum client bus throughput whatever is the number of requesting hosts.

13.7 Fixed Default Host

After the end of the current access, if no other request is pending, the client connects to its fixed default host. Unlike the last access host, the fixed default host does not change unless the user modifies it by software (FIXED_DEFMSTR field of the related MATRIX_SCFG).

This allows the MATRIX arbiters to remove the one latency clock cycle for the fixed default host of the client. All requests attempted by the fixed default host do not cause any arbitration latency, whereas other non-privileged hosts get one latency cycle. This technique is useful for a host that mainly performs single accesses or short bursts with Idle cycles in-between.

This configuration provides no benefit on access latency or bandwidth when reaching maximum client bus throughput, regardless of the number of requesting hosts.

13.8 Arbitration

The MATRIX provides an arbitration technique that reduces latency when conflicts occur, i.e., when two or more hosts try to access the same client at the same time. One arbiter per client is provided, thus arbitrating each client specifically.

The user can either choose one of the following arbitration types, or mix them for each client:

1. Round-robin Arbitration (default)
2. Fixed Priority Arbitration

The resulting algorithm may be complemented by selecting a default host configuration for each client.

When re-arbitration must be done, specific conditions apply. See section 13.8.1. Arbitration Scheduling .

13.8.1 Arbitration Scheduling

Each arbiter has the ability to arbitrate between two or more different host requests. In order to avoid burst breaking as well as to provide the maximum throughput for client interfaces, arbitration may only take place during the following cycles:

- Idle Cycles: When a client is not connected to any host or is connected to a host which is not currently accessing it.
- Single Cycles: When a client is currently doing a single access.
- End of Burst Cycles: When the current cycle is the last cycle of a burst transfer. For defined length burst, predicted end of burst matches the size of the transfer but is managed differently for undefined length burst. See section 13.8.1.1. Undefined Length Burst Arbitration.
- Slot Cycle Limit: When the slot cycle counter has reached the limit value indicating that the current host access is too long and must be broken. See section 13.8.1.2. Slot Cycle Limit Arbitration.

13.8.1.1 Undefined Length Burst Arbitration

In order to prevent long burst lengths that can lock the access to the client for an excessive period of time, the user can trigger the re-arbitration before the end of the incremental bursts. The re-arbitration period can be selected from the following Undefined Length Burst Type (ULBT) possibilities:

- Unlimited: no predetermined end of burst is generated. This value enables 1 Kbyte burst lengths.
- 1-beat bursts: predetermined end of burst is generated at each single transfer during the INCR transfer.
- 4-beat bursts: predetermined end of burst is generated at the end of each 4-beat boundary during INCR transfer.
- 8-beat bursts: predetermined end of burst is generated at the end of each 8-beat boundary during INCR transfer.
- 16-beat bursts: predetermined end of burst is generated at the end of each 16-beat boundary during INCR transfer.
- 32-beat bursts: predetermined end of burst is generated at the end of each 32-beat boundary during INCR transfer.
- 64-beat bursts: predetermined end of burst is generated at the end of each 64-beat boundary during INCR transfer.
- 128-beat bursts: predetermined end of burst is generated at the end of each 128-beat boundary during INCR transfer.

Undefined-length bursts lower than 8 beats should not be used since this may decrease the overall bus bandwidth due to arbitration and client latencies at each first access of a burst.

However, if the length of undefined-length bursts is known for a host, it is recommended to configure MATRIX_MCFG.ULBT accordingly.

13.8.1.2 Slot Cycle Limit Arbitration

The MATRIX contains specific logic to break long accesses, such as very long bursts on a very slow client (e.g., an external low speed memory). At each arbitration time, a counter is loaded with the value previously written in MATRIX_SCFGx.SLOT_CYCLE and decreased at each clock cycle. When the counter elapses, the arbiter has the ability to re-arbitrate at the end of the current system bus access cycle.

Unless a host has a very tight access latency constraint, which could lead to data overflow or underflow due to a badly undersized internal FIFO with respect to its throughput, the Slot Cycle Limit should be disabled (SLOT_CYCLE = 0) or set to its default maximum value in order not to inefficiently break long bursts performed by some hosts.

In most cases, this feature is not needed and should be disabled for power saving.

⚠WARNING This feature cannot prevent any client from locking its access indefinitely.

13.8.2 Arbitration Priority Scheme

The MATRIX arbitration scheme is organized in priority pools, each corresponding to an access criticality class as shown in the “Latency Quality of Service” column in the table below. When the Latency Quality of Service is enabled for a host-client pair through the MATRIX, the priority pool number to use for arbitration at the client port is determined from the host. When the Latency Quality of Service is disabled, it is determined through the MATRIX user interface. See 13.11.3. MATRIX_PRASx.

After reset, the Latency Quality of Service is enabled by default on all of the host ports that are connected to a host driving the Latency Quality of Service signals, as shown in the bit LQOSEN of 13.11.3. MATRIX_PRASx and 13.11.4. MATRIX_PRBSx.

Table 13-1. Arbitration Priority Pools

Priority Pool	Latency Quality of Service
3	Latency Critical
2	Latency Sensitive
1	Bandwidth Sensitive
0	Background Transfers

Round-robin priority is used in the highest and lowest priority pools 3 and 0, whereas fixed level priority is used between priority pools and in the intermediate priority pools 2 and 1.

For each client, each host is assigned to one of the client priority pools based on the Latency Quality of Service inputs or to the priority registers for clients (MxPR fields of MATRIX_PRAS and MATRIX_PRBS). When evaluating host requests, this priority pool level always takes precedence.

After reset, most of the hosts belong to the lowest priority pool (MxPR = 0, Background Transfer) and are therefore granted bus access in a true round-robin order.

The highest priority pool must be specifically reserved for hosts requiring very low access latency. If more than one host belongs to this pool, those hosts are granted bus access in a biased round-robin manner which enables tight and deterministic maximum access latency from system bus requests. In the worst case, any currently occurring high-priority host request is granted after the current bus host access has ended and any other high priority pool host requests have been granted once each.

The lowest priority pool shares the remaining bus bandwidth between hosts.

Intermediate priority pools enable fine priority tuning. Typically, a latency-sensitive host or a bandwidth-sensitive host use such a priority level. The higher the priority level (MxPR value), the higher the host priority.

For good CPU performance, it is recommended to let the CPU priority configured with the default reset value 2 (Latency Sensitive).

All combinations of MxPR values are allowed for all hosts and clients. For example, some hosts might be assigned the highest priority pool (round-robin), and remaining hosts the lowest priority pool (round-robin), with no host for intermediate fixed priority levels.

13.8.2.1 Fixed Priority Arbitration

The fixed priority arbitration algorithm is the first and only arbitration algorithm applied between hosts from distinct priority pools. It is also used in priority pools other than the highest and lowest priority pools (intermediate priority pools).

Fixed priority arbitration enables the MATRIX arbiters to dispatch the requests from different hosts to the same client by using the fixed priority defined by the user in the MxPR field for each host in the registers, MATRIX_PRAS and MATRIX_PRBS. If two or more host requests are active at the same time, the host with the highest priority MxPR number is serviced first.

In intermediate priority pools, if two or more host requests with the same priority are active at the same time, the host with the highest number is serviced first.

13.8.2.2 Round-Robin Arbitration

This algorithm is only used in the highest and lowest priority pools. It allows the MATRIX arbiters to properly dispatch requests from different hosts to the same client. If two or more host requests are active at the same time in the priority pool, they are serviced in a round-robin increasing host number order.

13.9 Register Write Protection

To prevent any single software error from corrupting MATRIX behavior, certain registers in the address space can be write-protected by setting the WPEN bit in the Write Protection Mode register (MATRIX_WPMR).

If a write access to a write-protected register is detected, the WPVS flag in the Write Protection Status register (MATRIX_WPSR) is set and the field WPVSRC indicates the register in which the write access has been attempted.

The WPVS flag is reset by writing the MATRIX_WPMR with the appropriate access key WPKEY.

The registers listed below can be write-protected.

13.10 TrustZone Extension

TrustZone secure software is supported through the filtering of each client access with host security bit extension signals.

TrustZone technology adds the ability to manage the access rights for Secure and Non-Secure accesses. The access rights are defined through the hardware and software configuration of the device. The operating mode is the following:

- Hosts transmit requests with the secure or non-secure Security option.
- The MATRIX, according to its configuration and the request, grants or denies the access.

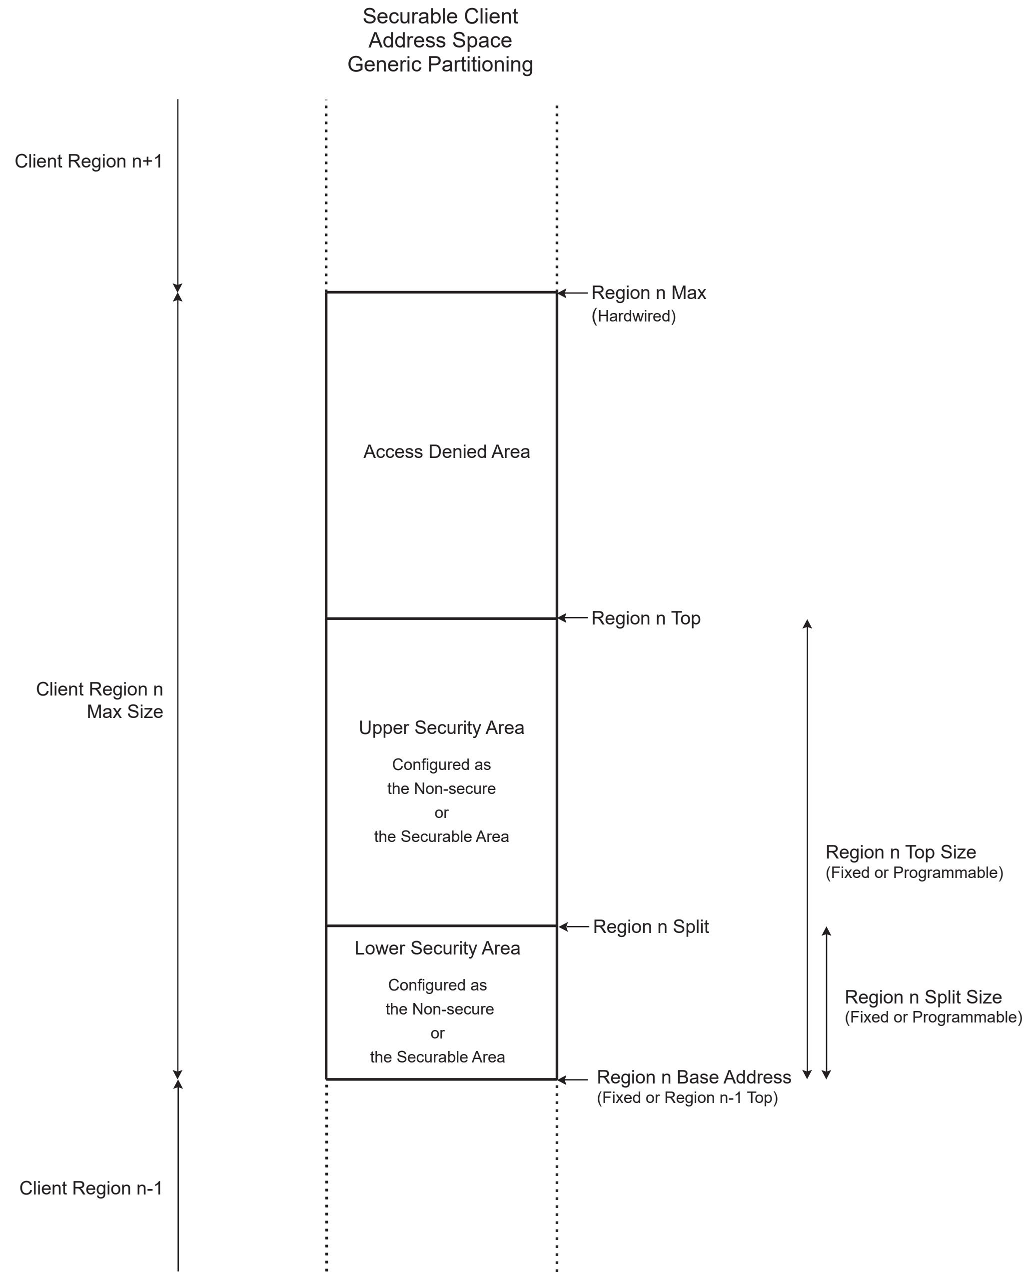
The client address space is divided into one or more client regions. The client regions are generally contiguous parts of the client address space. The client region is potentially split into an access denied area (upper part) and a security region which can be split (lower part), unless the client security region occupies the whole client region. The security region itself can be split into one secure area and one non-secure area. The secure area may be independently secured for read access and for write access.

For one client region, the following characteristics are configured by hardware or software:

- Base Address of the client region
- Max Size of the client region—a maximum size for the region's physical content
- Top Size of the client security region— the actually programmed or fixed size for the region's physical content
- Split Size of the client security region— the size of one of the two security areas of the region

The following figure shows how the terms defined here are implemented in a client address space.

Figure 13-1. Generic Partitioning of the Client Address Space



A set of security registers specifies, for each client, the client security region or client security area, the security mode required to access this client, client security region or client security area. See section 13.11.13. MATRIX_SSRx, 13.11.14. MATRIX_SASSRx and 13.11.15. MATRIX_SRTSRx.

These registers can only be accessed in Secure mode.

The MATRIX propagates the security bit down to the clients to let them perform additional security checks, and the MATRIX itself allows or denies the access to the clients by means of its TrustZone embedded controller.

Access violations may be reported either by a client through the bus error response, or by the embedded TrustZone controller. In both cases, a bus error response is sent to the offending host and the error is flagged in the Host Error Status Register. An interrupt can be sent to the Secure world, if it has been enabled for that host by writing into the

Host Error Interrupt Enable Register. Thus, the offending host is identified. The offending address is registered in the Host Error Address Registers, so that the client and the targeted security region are also known.

Depending on the hardware parameters and software configuration, the address space of each client security region may or may not be split into two parts, one belonging to the Secure world and the other one to the Normal world.

Five different security types of clients are supported. The number of security regions is set by design for each client, independently, from 1 to 8, totaling from 1 up to 16 security areas for each security-configurable client.

13.10.1 Security Types of System Bus Clients

13.10.1.1 Principles

The MATRIX supports five different security types of clients: two fixed types and three configurable types. The security type of a client is set at hardware design among the following:

- Never Secure
- Always Secure
- Internal Securable
- External Securable
- Scalable Securable

The security type is set at hardware design on a per-host and a per-client basis. Never Secure and Always Secure security types are not software configurable.

The different security types have the following characteristics:

- **Never Secure** clients have no security mode access restriction. Their address space is precisely set by design. Any out-of-address range access is denied and reported.
- **Always Secure** clients can only be accessed by a secure host request. Their address space is precisely set by design. Any non-secure or out-of-address range access is denied and reported.
- **Internal Securable** is intended for internal RAM. The Internal Securable client has one client region which has a hardware fixed base address and Security Region Top. This client region may be split through software configuration into one Non-secure area plus one Secure area. Inside the client security region, the split boundary is programmable in powers of 2 from 4 Kbytes up to the full client security region address space. The security area located below the split boundary may be configured as the Non-secure or the Secure one. The Securable area may be independently configured as Read Secured and/or Write Secured. Any access with security or address range violation is denied and reported.
- **External Securable** is intended for external memories on the EBI, such as DDR, SDRAM, external ROM or NAND Flash. The External Securable client has identical features as the Internal Securable client, plus the ability to configure each of its client security region address space sizes according to the external memory parts used. This avoids mirroring Secure areas into Non-secure areas, and further restricts the overall accessible address range. Any access with security or configured address range violation is denied and reported.
- **Scalable Securable** is intended for external memories with a dedicated client, such as DDR. The Scalable Securable client is divided into a fixed number of scalable, equally sized, and contiguous security regions. Each of them can be split in the same way as for Internal or External Securable clients. The security region size must be configured by software, so that the equally-sized regions fill the actual available memory. This avoids mirroring Secure areas into Non-secure areas, and further restricts the overall accessible address range. Any access with security or configured address range violation is denied and reported.

As the security type is set at hardware design on a per-host and per-client basis, it is possible to set some client access security as configurable from one or some particular hosts, and to set the access as Always Secure from all the other hosts.

As the security type is set by design at the client region level, different security region types can be mixed inside a single client.

Likewise, the mapping base address and the accessible address range of each client or client region may have been hardware-restricted on a per-host basis from no access to full client address space.

13.10.1.2 Examples

The table below shows an example of Security Type settings.

Table 13-2. Security Type Setting Example

Client	Host0	Host1	Host2
Client0 Internal Memory	Always Not Secured	Internal Securable 1 Region	Internal Securable 1 Region
Client1 EBI	External Securable 2 Regions	Always Secured	External Securable 2 Regions

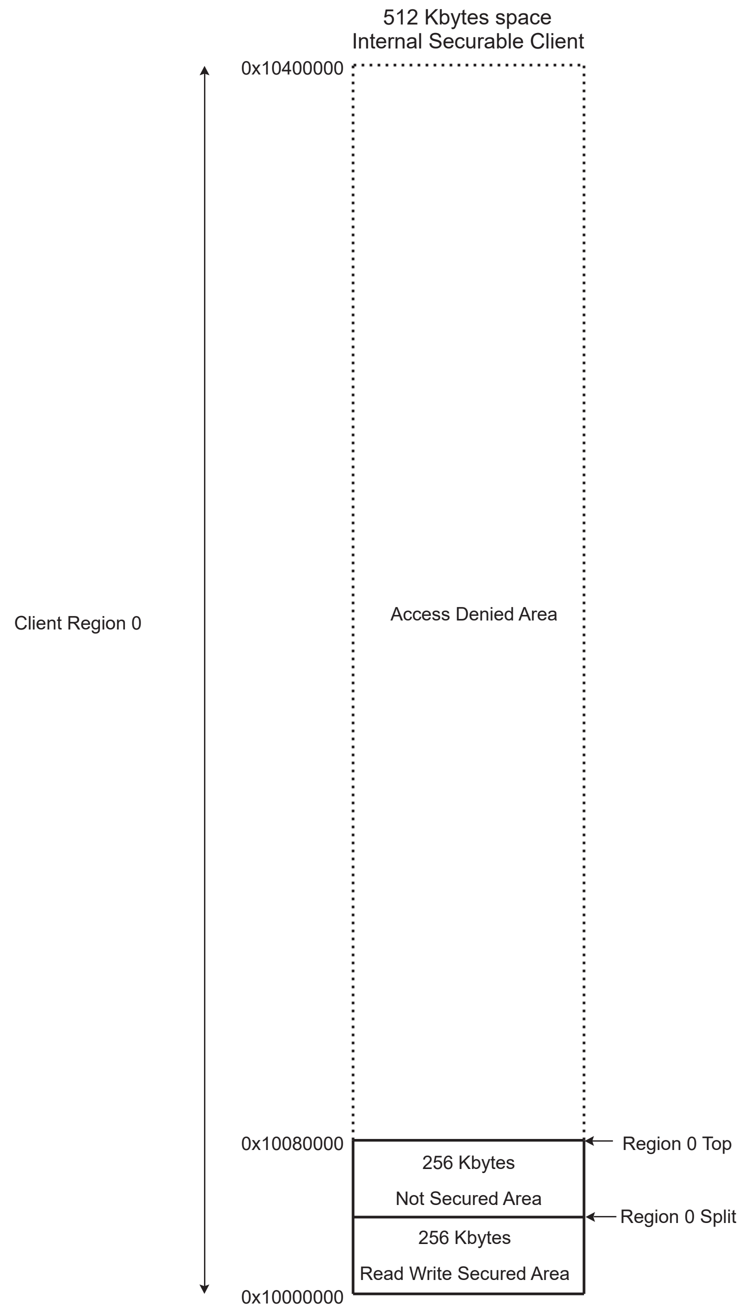
This example is constructed with the following characteristics:

- Client0 is an Internal Memory containing one region:
  - The Access from Host0 to Client0 is Never Secure
  - The access from Host1 and Host2 to Client0 is Internal Securable with one region and with the same software configuration (Choice of SASPLIT0 and the security configuration bits LANSECH, RDNSECH, WRNSECH).
- Client1 is an EBI containing two regions:
  - The access from Host1 to Client1 is Always Secure
  - The access from Host0 and Host2 to Client1 is External Securable with two regions and with the same software configuration (Choice of SRTOP0, SRTOP1, SASPLIT0, SASPLIT1 and the security configuration bits LANSECH, RDNSECH, WRNSECH).

The following figure shows an Internal Securable client example. This example is constructed with the following hypothesis:

- The client is an Internal Memory containing one region. The Client region Max Size is 4 Mbytes.
- The client region 0 base address equals 0x10000000. Its Top Size is 512 Kbytes (hardware configuration).
- The client software configuration is:
  - SASPLIT0 is set to 256 Kbytes.
  - LANSECH0 is set to 0, the low area of region 0 is the Securable one.
  - RDNSECH0 is set to 0, region 0 Securable area is secured for reads.
  - WRNSECH0 is set to 0, region 0 Securable area is secured for writes.

Figure 13-2. Partitioning Example of an Internal Securable Client Featuring 1 Security Region of 512 Kbytes Split into 1 or 2 Security Areas of 4 Kbytes to 512 Kbytes



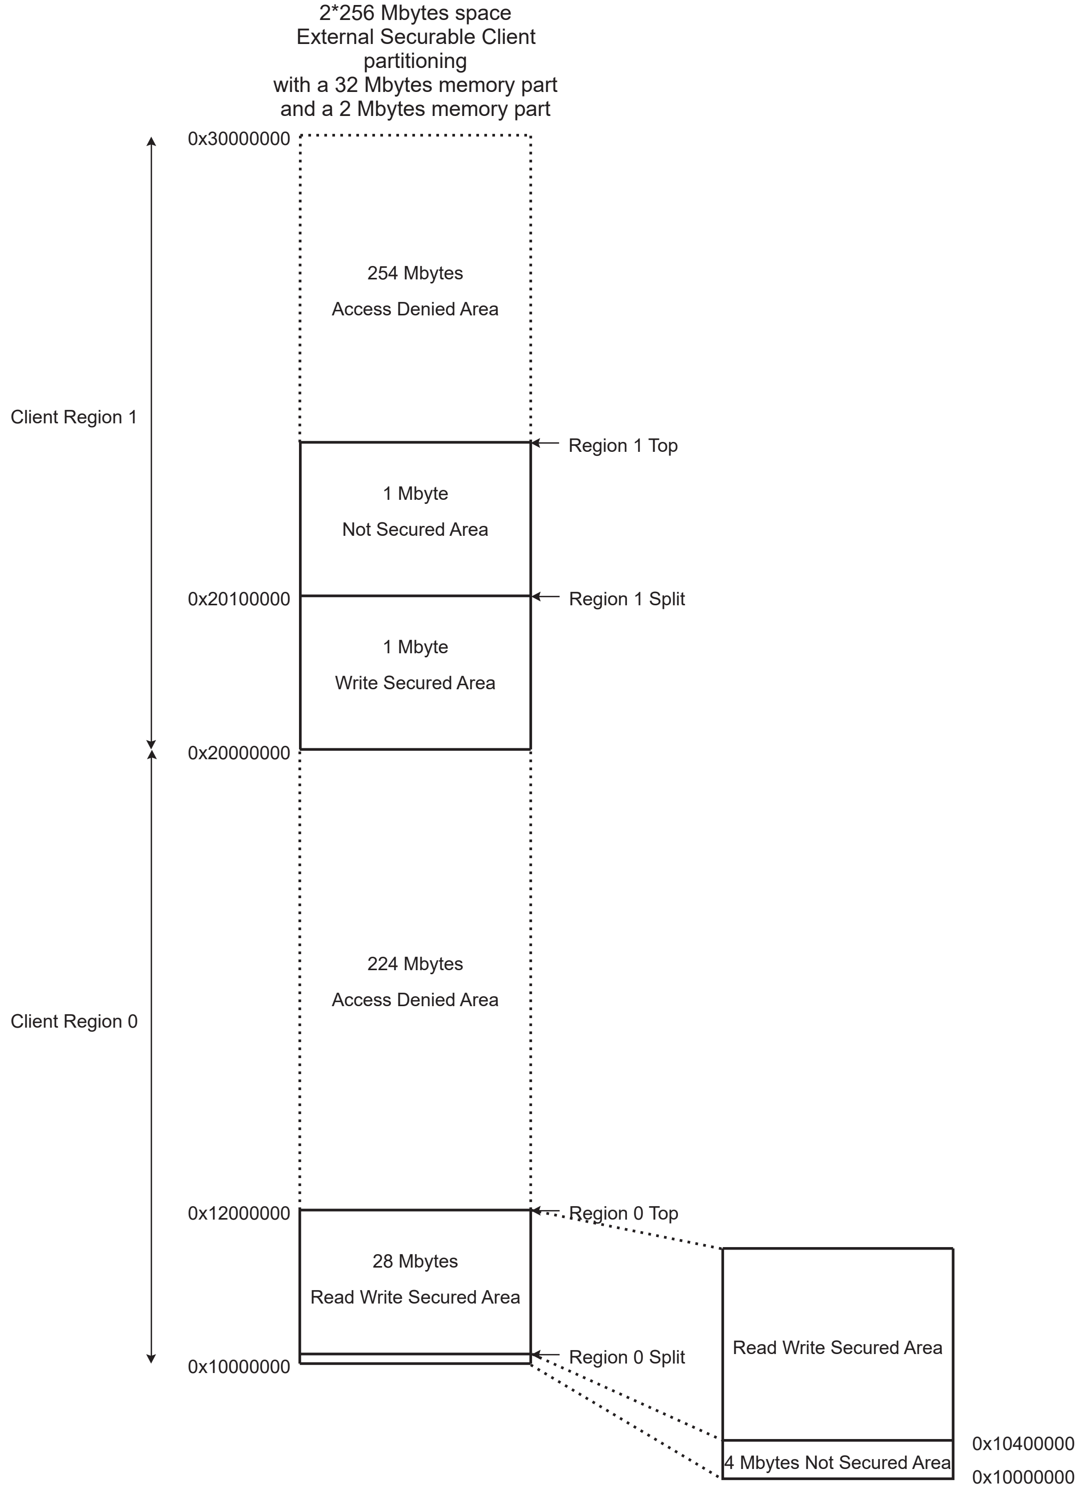
Note: The client security areas split inside the security region are configured by writing into the Security Areas Split Client Registers.

The following figure shows an External Securable client example. This example is constructed with the following hypothesis:

- The client is an interface with the external bus (EBI) containing two regions. The client size is 2 ´ 256 Mbytes. Each client region max size is 256 Mbytes.
- The client region 0 base address equals 0x10000000. It is connected to a 32 Mbyte memory, for example an external DDR. The client region 0 top size must be set to 32 Mbytes.
- The client region 1 base address equals 0x20000000. It is connected to a 2 Mbyte memory, for example an external NAND Flash. The client region 1 top size must be set to 2 Mbytes.

- The client software configuration is:
  - SRTOP0 is set to 32 Mbytes
  - SRTOP1 is set to 2 Mbytes
  - SASPLIT0 is set to 4 Mbytes
  - SASPLIT1 is set to 1 Mbyte
  - LANSECH0 is set to 1, the low area of region 0 is the non-Securable one
  - RDNSECH0 is set to 0, region 0 Securable area is secured for reads
  - WRNSECH0 is set to 0, region 0 Securable area is secured for writes
  - LANSECH1 is set to 0, the low area of region 1 is the Securable one
  - RDNSECH1 is set to 1, region 1 Securable area is non-secured for reads
  - WRNSECH1 is set to 0, region 1 Securable area is secured for writes

Figure 13-3. Partitioning Example: External Securable Client Featuring 2 Security Regions of 4 Kbytes to 128 Mbytes Each and Up to 4 Security Areas of 4 Kbytes to 128 Mbytes

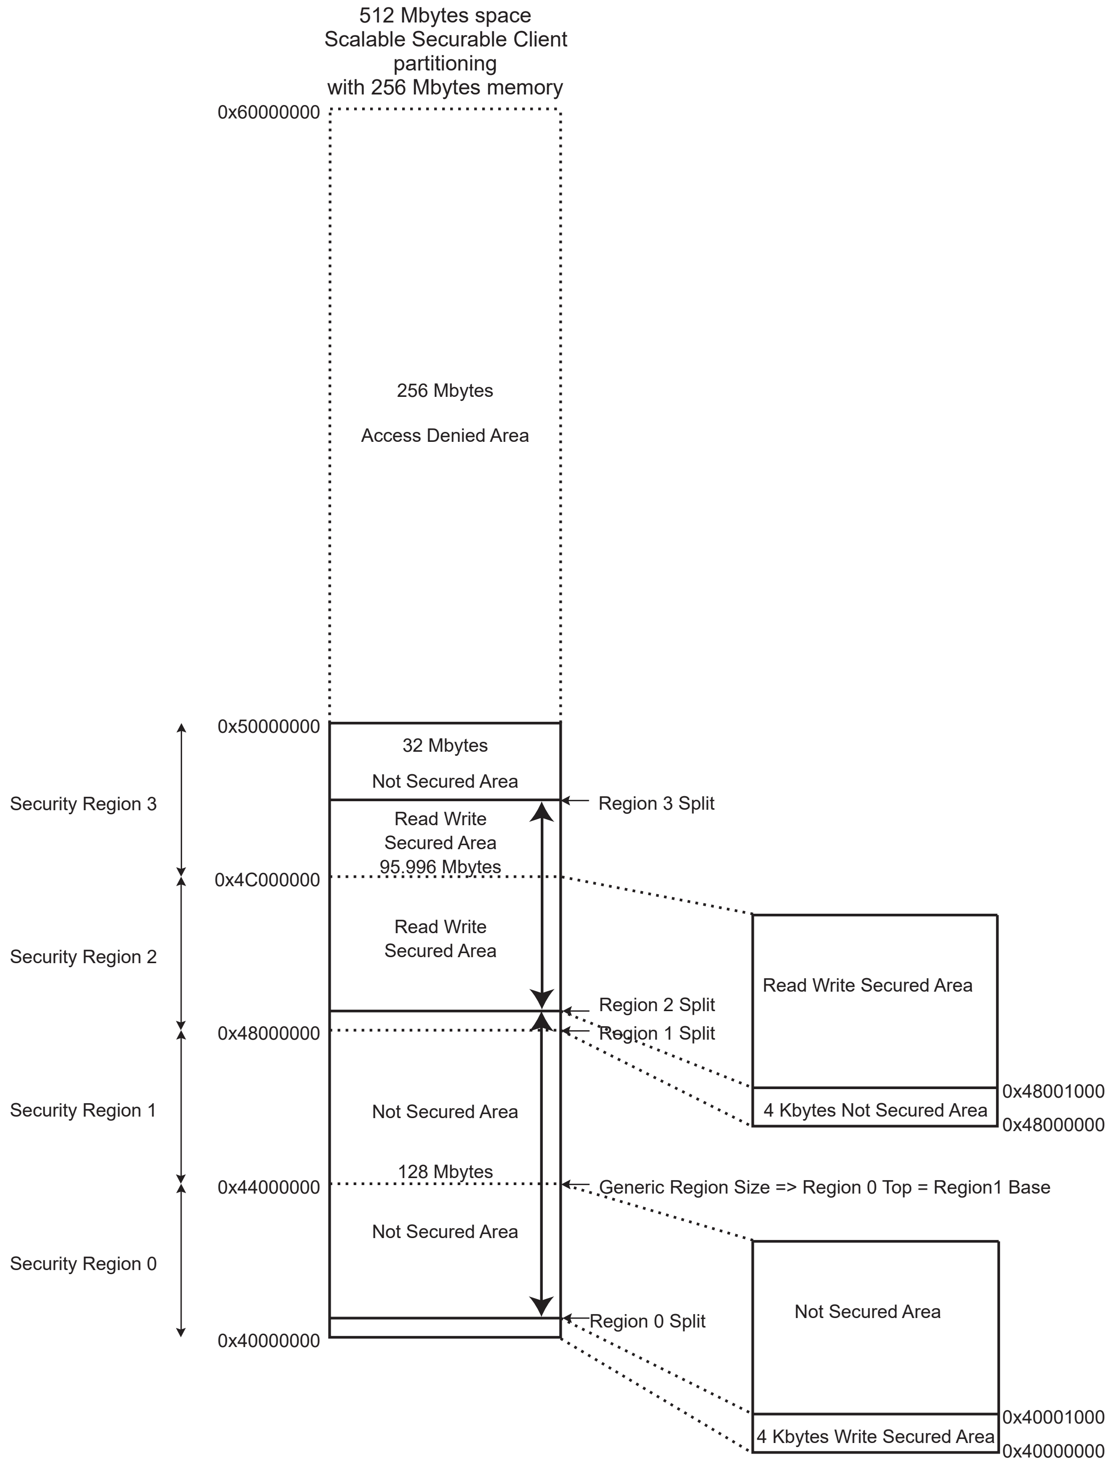


Note: The client region sizes are configured by writing into the Security Region Top Client Registers. The client security area split inside each region is configured by writing into the Security Areas Split Client Registers.

The following figure shows a Scalable Securable client example. This example is constructed with the following hypothesis:

- The client is an external memory with dedicated client containing four regions, for example an external DDR.
- The client size is 512 Mbytes.
- The client base address equals 0x40000000. It is connected to a 256-Mbyte external memory.
- As the connected memory size is 256 Mbytes and there are four regions, the size of each region is 64 Mbytes. This gives the value of the client region max size and top size. The client region 0 Top Size must be configured to 64 Mbytes.
- The client software configuration is as follows:
  – SRTOP0 is set to 64 Mbytes
  – SASPLIT0 is set to 4 Kbytes
  – SASPLIT1 is set to 64 Mbytes, so its low area occupies the whole region 1
  – SASPLIT2 is set to 4 Kbytes
  – SASPLIT3 is set to 32 Mbytes
  – LANSECH0 is set to 0, the low area of region 0 is the Securable one
  – RDNSECH0 is set to 1, region 0 Securable area is not secured for reads.
  – WRNSECH0 is set to 0, region 0 Securable area is secured for writes.
  – LANSECH1 is set to 1, the low area of region 1 is the non-securable one.
  – RDNSECH1 is ‘don’t care’ since the low area occupies the whole region 1.
  – WRNSECH1 is ‘don’t care’ since the low area occupies the whole region 1.
  – LANSECH2 is set to 1, the low area of region 2 is the non-Securable one.
  – RDNSECH2 is set to 0, region 2 Securable area is secured for reads
  – WRNSECH2 is set to 0, region 2 Securable area is secured for writes
  – LANSECH3 is set to 0, the low area of region 3 is the Securable one.
  – RDNSECH3 is set to 0, region 3 Securable area is secured for reads.
  – WRNSECH3 is set to 0, region 3 Securable area is secured for writes.

Figure 13-4. Partitioning Example: Scalable Securable Client Featuring 4 Equally-sized Security Regions of 1 Mbytes to 128 Mbytes Each and Up to 8 Security Areas of 4 Kbytes to 128 Mbytes



Note: The clients' generic security regions sizes are configured by writing into field SRTOP0 of the Security Region Top Client Registers. The custom client security areas split inside each region are configured by writing into the Security Areas Split Client Registers.

13.10.2 Security Types of System Bus Hosts

Hosts send requests to the MATRIX with a security attribute that depends on the host security type, which is identical to the security type of the client user interface.

For DMA, the TrustZone security attribute can be selected for each channel. Refer to the section “Extensible DMA Controller (XDMAC)”.

13.10.3 Security of Peripheral Bus Clients

To configure the security mode required for accessing a peripheral bus client connected behind the system-to-peripheral bus (AHB/APB Bridge), the MATRIX features three 32-bit Security Peripheral Select x Registers. Some of these bits may have been set by design to an Always Secure or a Never Secure value, when others are programmed by software (see 13.11.16. MATRIX_SPSELRx).

The system-to-peripheral bus bridge compares the incoming host request security bit with the required security mode for the selected peripheral, and accepts or denies access. In the last case, its bus error response is internally flagged in the Host Error Status Register; the offending address is registered in the Host Error Address Registers.

13.11 Register Summary

13.11.1 MATRIX Host Configuration Register x

Name: MATRIX_MCFGx
Offset: 0x00 + x*0x04 [x=0..14]
Reset: 0x00000004
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
							ULBT[2:0]	
Access						R/W	R/W	R/W
Reset						1	0	0

Bits 2:0 – ULBT[2:0] Undefined Length Burst Type

Value	Name	Description
0	UNLIMITED	Unlimited Length Burst—No predicted end of burst is generated, therefore INCR bursts coming from this host can only be broken if the Client Slot Cycle Limit is reached. If the Slot Cycle Limit is not reached, the burst is normally completed by the host, at the latest, on the next system bus 1 Kbyte address boundary, allowing up to 256-beat word bursts or 128-beat double-word bursts. This value should not be used in the very particular case of a host capable of performing back-to-back undefined length bursts on a single client, since this could indefinitely freeze the client arbitration and thus prevent another host from accessing this client.
1	SINGLE	Single Access—The undefined length burst is treated as a succession of single accesses, allowing re-arbitration at each beat of the INCR burst or bursts sequence.
2	4_BEAT	4-beat Burst—The undefined length burst or bursts sequence is split into 4-beat bursts or less, allowing re-arbitration every 4 beats.
3	8_BEAT	8-beat Burst—The undefined length burst or bursts sequence is split into 8-beat bursts or less, allowing re-arbitration every 8 beats.
4	16_BEAT	16-beat Burst—The undefined length burst or bursts sequence is split into 16-beat bursts or less, allowing re-arbitration every 16 beats.
5	32_BEAT	32-beat Burst—The undefined length burst or bursts sequence is split into 32-beat bursts or less, allowing re-arbitration every 32 beats.
6	64_BEAT	64-beat Burst—The undefined length burst or bursts sequence is split into 64-beat bursts or less, allowing re-arbitration every 64 beats.
7	128_BEAT	128-beat Burst—The undefined length burst or bursts sequence is split into 128-beat bursts or less, allowing re-arbitration every 128 beats. Unless duly needed, the ULBT should be left at its default 0 value for power saving.

13.11.2 MATRIX Client Configuration Register x

Name: MATRIX_SCFGx
Offset: 0x40 + x*0x04 [x=0..9]
Reset: 0x000001FF
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the Write Protection Mode Register.

–

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
			FIXED_DEFMSTR[3:0]				DEFMSTR_TYPE[1:0]	
Access			R/W	R/W	R/W	R/W	R/W	R/W
Reset			0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8

Access								R/W
Reset								1

Bit	7	6	5	4	3	2	1	0
	SLOT_CYCLE[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	1	1	1	1	1	1	1	1

Bits 21:18 – FIXED_DEFMSTR[3:0] Fixed Default Host
This is the number of the Default Host for this client. Only used if DEFMSTR_TYPE is 2. Specifying the number of a host which is not connected to the selected client is equivalent to setting DEFMSTR_TYPE to 0.

Bits 17:16 – DEFMSTR_TYPE[1:0] Default Host Type

Value	Name	Description
0	NONE	No Default Host—At the end of the current client access, if no other host request is pending, the client is disconnected from all hosts. This results in a one clock cycle latency for the first access of a burst transfer or for a single access.
1	LAST	Last Default Host—At the end of the current client access, if no other host request is pending, the client stays connected to the last host having accessed it. This results in not having one clock cycle latency when the last host tries to access the client again.
2	FIXED	Fixed Default Host—At the end of the current client access, if no other host request is pending, the client connects to the fixed host the number that has been written in the FIXED_DEFMSTR field. This results in not having one clock cycle latency when the fixed host tries to access the client again.

Bits 8:0 – SLOT_CYCLE[8:0] Maximum Bus Grant Duration for Hosts
When SLOT_CYCLE system bus clock cycles have elapsed since the last arbitration, a new arbitration takes place to let another host access this client. If another host is requesting the client bus, then the current host burst is broken.

If SLOT_CYCLE = 0, the Slot Cycle Limit feature is disabled and bursts always complete unless broken according to the ULBT.
This limit has been placed in order to enforce arbitration so as to meet potential latency constraints of hosts waiting for client access.
This limit must not be too small. Unreasonably small values break every burst and the MATRIX arbitrates without performing any data transfer. The default maximum value is usually an optimal conservative choice.
In most cases, this feature is not needed and should be disabled for power saving.
See section Slot Cycle Limit Arbitration for details.

13.11.3 MATRIX Priority Register A For Clients x

Name: MATRIX_PRASx
Offset: 0x80 + x*0x08 [x=0..9]
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
		LQOSEN7	M7PR[1:0]			LQOSEN6	M6PR[1:0]	
Access		R/W	R/W	R/W		R/W	R/W	R/W

		LQOSEN1	M1PR[1:0]			LQOSEN0	M0PR[1:0]	
Access		R/W	R/W	R/W		R/W	R/W	R/W
Reset		0	0	0		0	0	0

Bits 2, 6, 10, 14, 18, 22, 26, 30 – LQOSENx Latency Quality of Service Enable for Host x

Value	Description
0	Disables propagation of Latency Quality of Service from the Host x to the Client and apply MxPR priority for all access from Host x to the Client.
1	Enables the propagation of Latency Quality of Service from the Host x to the Client if supported by the Host x.

Bits 0:1, 4:5, 8:9, 12:13, 16:17, 20:21, 24:25, 28:29 – MxPR Host x Priority
Fixed priority of Host x for accessing the selected client. The higher the number, the higher the priority.
All the hosts programmed with the same MxPR value for the client make up a priority pool.
Round-robin arbitration is used in the lowest (MxPR = 0) and highest (MxPR = 3) priority pools.
Fixed priority is used in intermediate priority pools (MxPR = 1) and (MxPR = 2).
See section Arbitration Priority Scheme for details.
If LQOSENx bit is cleared, then this priority value is used as it for arbitration and downward propagation to the client.
If LQOSENx bit is set, then this priority acts as the upper limit for the Latency Quality of Service from Host x.
For hosts other than the CPU, the usual value of this field should be 0x0 if LQOSENx bit is cleared, and 0x1 if LQOSENx bit is set. For the CPU host, the usual value of this field should be 0x2.

13.11.4 MATRIX Priority Register B For Clients x

Name: MATRIX_PRBSx
Offset: 0x84 + x*0x08 [x=0..9]
Reset: 0x00000000

	CFGFRZ							WPEN
Access	R/W							R/W
Reset	0							0

Bits 31:8 – WPKEY[23:0] Write Protection Key

Value	Name	Description
0x4D4154	PASSWD	Writing any other value in this field aborts the write operation of the WPEN and CFGFRZ bits. Always reads as 0.

Bit 7 – CFGFRZ Configuration Freeze

Value	Description
0	The MATRIX configuration is not frozen.
1	Freezes the MATRIX configuration until hardware reset. The registers that can be protected by the WPEN bit and the Write Protection Mode Register are no longer modifiable.

Bit 0 – WPEN Write Protection Enable
See section Register Write Protection for the list of registers that can be write-protected.

Value	Description
0	Disables the write protection if WPKEY corresponds to 0x4D4154 (“MAT” in ASCII).
1	Enables the write protection if WPKEY corresponds to 0x4D4154 (“MAT” in ASCII).

13.11.12 MATRIX Write Protection Status Register

Name: MATRIX_WPSR
Offset: 0x01E8

Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
								WPVS
Access								R
Reset								0

Bits 23:8 – WPVSRC[15:0] Write Protection Violation Source
When WPVS = 1, WPVSRC indicates the register address offset at which a write access has been attempted.

Bit 0 – WPVS Write Protection Violation Status

Value	Description
0	No write protection violation has occurred since the last write of the MATRIX_WPMR.
1	A write protection violation has occurred since the last write of the MATRIX_WPMR. If this violation is an unauthorized attempt to write a protected register, the associated violation is reported into field WPVSRC.

13.11.13 MATRIX Security Client Register x

Name: MATRIX_SSRx
Offset: 0x0200 + x*0x04 [x=0..9]
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24

Bits 24, 25, 26, 27, 28, 29, 30, 31 – DSSOAx Downward Security Split Offset Address for HSELx Security Region

Value	Description
0	For the HSELx client security region, the security area split MATRIX_SASSR / SASPLITx defines the size of the client security area starting from the base address of the client security region and up.
1	For the HSELx client security region, the security area split MATRIX_SASSR / SASPLITx defines the size of the client security area starting from the end address of the client security region and down.

Bits 16, 17, 18, 19, 20, 21, 22, 23 – WRNSECHx Write Not Secured for HSELx Security Region
Securable Area access rights:

WRNSECHx / RDNSECHx	Non-Secure Access	Secure Access
00	Denied	Write - Read
01	Read	Write - Read
10	Write	Write - Read
11	Write - Read	Write - Read

Value	Description
0	The HSELx client security region is split into one Write Secured and one Write Not Secured area, according to LANSECHx and MATRIX_SASSR / SASPLITx. That is, the so defined securable high or low area is Secured for Write access.
1	The HSELx client security region is Not Secured for Write access.

Bits 8, 9, 10, 11, 12, 13, 14, 15 – RDNSECHx Read Not Secured for HSELx Security Region

Value	Description
0	The HSELx client security region is split into one Read Secured and one Read Not Secured area, according to LANSECHx and MATRIX_SASSR / SASPLITx. That is, the so defined securable high or low area is Secured for Read access.
1	The HSELx client security region is Not Secured for Read access.

Bits 0, 1, 2, 3, 4, 5, 6, 7 – LANSECHx Low Area Not Secured in HSELx Security Region

Value	Description
0	The security of the HSELx client area laying below the corresponding MATRIX_SASSR / SASPLITx boundary is configured according to RDNSECHx and WRNSECHx. The whole remaining HSELx upper address space is configured as Not Secured access.
1	The HSELx client address area laying below the corresponding MATRIX_SASSR / SASPLITx boundary is configured as Not Secured access, and the whole remaining upper address space according to RDNSECHx and WRNSECHx.

13.11.14 MATRIX Security Areas Split Client Register x

Name: MATRIX_SASSRx
Offset: 0x0240 + x*0x04 [x=0..9]
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
	SASPLIT7[3:0]				SASPLIT6[3:0]			
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 0:3, 4:7, 8:11, 12:15, 16:19, 20:23, 24:27, 28:31 – SRTOPx HSELx Security Region Top
This field defines the size of the HSELx security region address space. Invalid sizes for the client region must never be programmed. Valid sizes and number of security regions are product, client and client configuration dependent.
Note: The clients featuring multiple scalable contiguous security regions have a single SRTOP0 field for all the security regions.

If this HSELx security region size is set at or below the MATRIX_SASSR / SASPLITx Security Areas Split size, then the MATRIX_SSR settings apply to the unique security area then covering the whole HSELx security region

SRTOPx	Top Offset	Security Region Size

13.11.16 MATRIX Security Peripheral Select x Register [x=1..3]

Name: MATRIX_SPSELRx
Offset: 0x02C0 + (x-1)*0x04 [x=1..3]
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the Write Protection Mode Register.

Each MATRIX_SPSELR can configure the access security type for up to 32 peripherals:

- MATRIX_SPSELR1 configures the access security type for peripheral identifiers 0–31 (bits NSECP0–NSECP31).
- MATRIX_SPSELR2 configures the access security type for peripheral identifiers 32–63 (bits NSECP0–NSECP31).
- MATRIX_SPSELR3 configures the access security type for peripheral identifiers 64–95 (bits NSECP0–NSECP31).

Values in the MATRIX Security registers are product-dependent.

The actual number of peripherals implemented is device-specific; refer to section “Peripheral Identifiers” for details.

Value	Description
0	The selected peripheral address space is configured as “Secured” access (value of ‘0’ has no effect if the peripheral security type is “Not Secured”).
1	The selected peripheral address space is configured as “Not Secured” access (value of ‘1’ has no effect if the peripheral security type is “Always Secured”).

14. DMA Controller (XDMAC)

14.1 Description

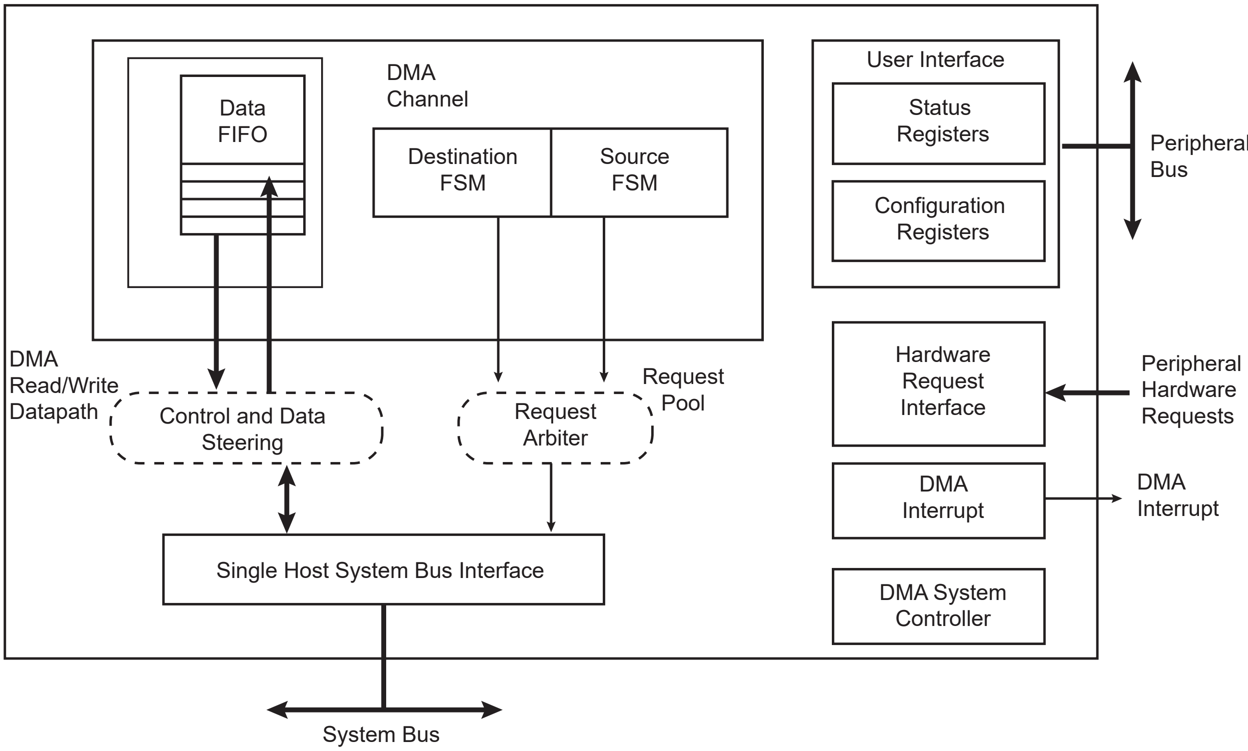
The DMA Controller (XDMAC) is a AXI-protocol central direct memory access controller. It performs peripheral data transfer and memory move operations over one or two bus ports through the unidirectional communication channel. Each channel is fully programmable and provides both peripheral or memory-to-memory transfers. The channel features are configurable at implementation.

14.2 Embedded Characteristics

- 1 System Bus Host Interface
- 32, 32 and 8 DMA Channels, Respectively, for XDMA0, XDMA1 and XDMA2
- 61 Hardware Requests
- 8448, 8448 and 2112 Kbytes Embedded FIFO, Respectively, for XDMA0, XDMA1 and XDMA2
- Supports Peripheral-to-Memory, Memory-to-Peripheral, or Memory-to-Memory Transfer Operations
- Peripheral DMA Operation Runs on Bytes (8-bit), Half-Word (16-bit) and Word (32-bit)
- Memory DMA Operation Runs on Bytes (8 bit), Half-Word (16-bit), Word (32-bit) and Double-Word (64-bit)
- Supports Hardware and Software Initiated Transfers
- Supports Linked List Operations
- Supports Incrementing or Fixed Addressing Mode
- Supports Programmable Independent Data Striding for Source and Destination
- Supports Programmable Independent Microblock Striding for Source and Destination
- Configurable Priority Group and Arbitration Policy
- Programmable AXI Burst Length
- Configuration Interface on Peripheral Bus
- XDMAC Architecture Includes Multiport FIFO
- Supports Multiple View Channel Descriptor
- Automatic Flush of Channel Trailing Bytes
- Automatic Coarse-Grain and Fine-Grain Clock Gating
- Hardware Acceleration of Memset Pattern
- Supports Configurable Quality of Service per Channel

14.3 Block Diagram

Figure 14-1. XDMAC Block Diagram



14.4 DMA Controller Peripheral Connections

DMA hardware requests are the same for XDMAC0 and XDMAC1. XDMAC2 is memory-to-memory dedicated, there is no hardware interface.

14.5 Functional Description

14.5.1 Basic Definitions

Source Peripheral: Client device, memory mapped on the interconnection network, from where the XDMAC reads data. The source peripheral teams up with a destination peripheral to form a channel. A data read operation is scheduled when the peripheral transfer request is asserted.

Destination Peripheral: Client device, memory mapped on the interconnection network, to which the XDMAC writes. A write data operation is scheduled when the peripheral transfer request is asserted.

Channel: The data movement between source and destination creates a logical channel.

Stride: Number of address locations between successive elements/data measured in bytes.

Transfer Type: The transfer is hardware-synchronized when it is paced by the peripheral hardware request, otherwise the transfer is self-triggered (memory to memory transfer).

XDMAC Host Transfer: The host transfer is composed of a linked list of blocks. The channel address, control and configuration registers can be modified at the inter block boundary. The descriptor structure modifies the channel registers conditionally. Interrupts can be generated on a per block basis or when the end of linked list event occurs.

XDMAC Block: An XDMAC block is composed of a programmable number of microblocks. The channel configuration registers remain unchanged at the inter microblock boundary. The source and destination addresses are conditionally updated with a programmable signed number.

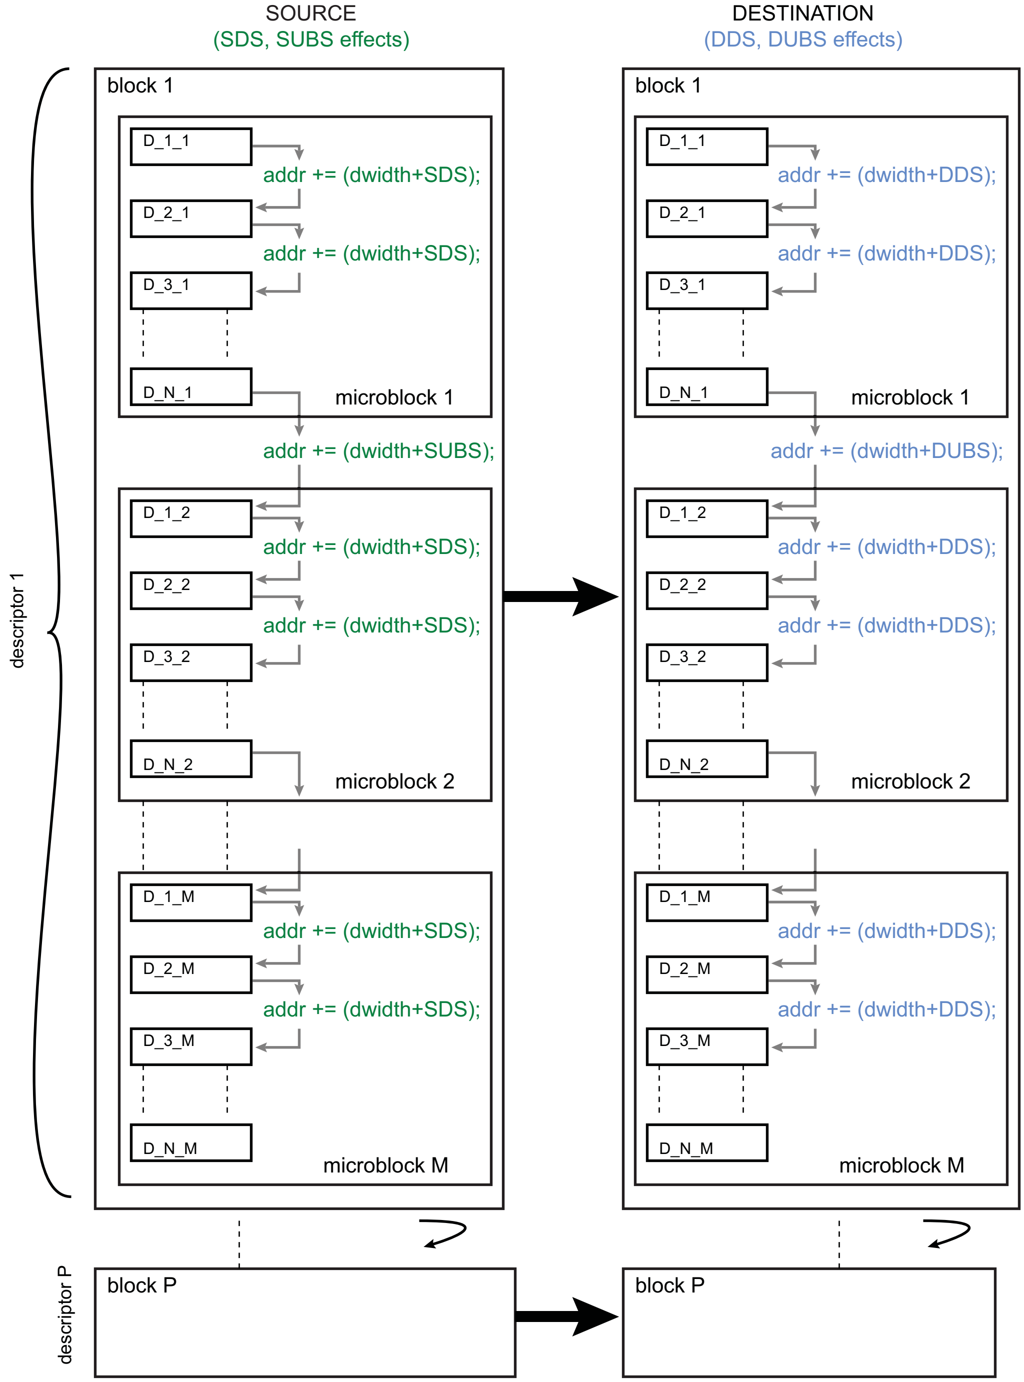
XDMAC Microblock: The microblock is composed of a programmable number of data. The channel configuration registers remain unchanged at the data boundary. The data address may be fixed (a FIFO location, a peripheral transmit or receive register), incrementing (a memory-mapped area) by a programmable signed number.

XDMAC Burst and Incomplete Burst: In order to improve the overall performance when accessing dynamic external memory, burst access is mandatory. Each data of the microblock is considered as a part of a memory burst. The programmable burst value indicates the largest memory burst allowed on a per channel basis. When the microblock length is not an integral multiple of the burst size, an incomplete burst is performed to read or write the last trailing bytes.

XDMAC Chunk and Incomplete Chunk: When a peripheral synchronized transfer is activated, the microblock splits into a number of data chunks. The chunk size is programmable. The larger the chunk is, the better the performance is. When the transfer size is not a multiple of the chunk size, the last chunk may be incomplete.

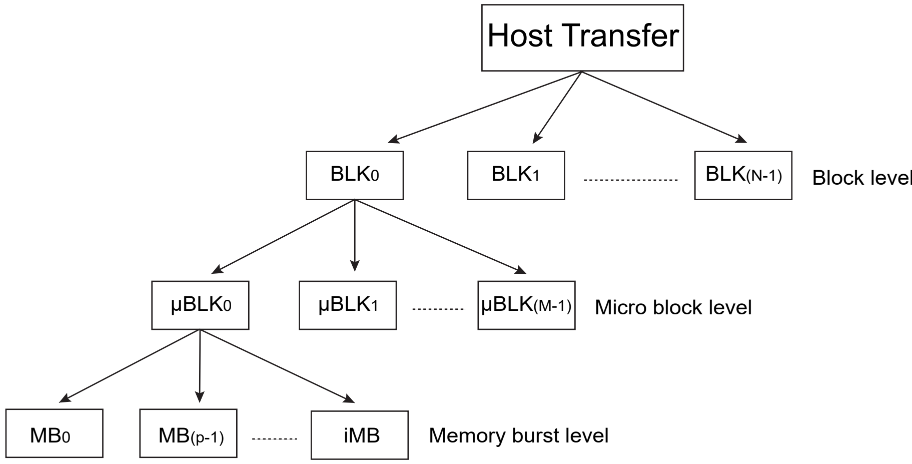
14.5.2 Data Striding Diagram

Figure 14-2. Data Striding Diagram



14.5.3 Transfer Hierarchy Diagrams

Figure 14-3. XDMAC Memory Transfer Hierarchy



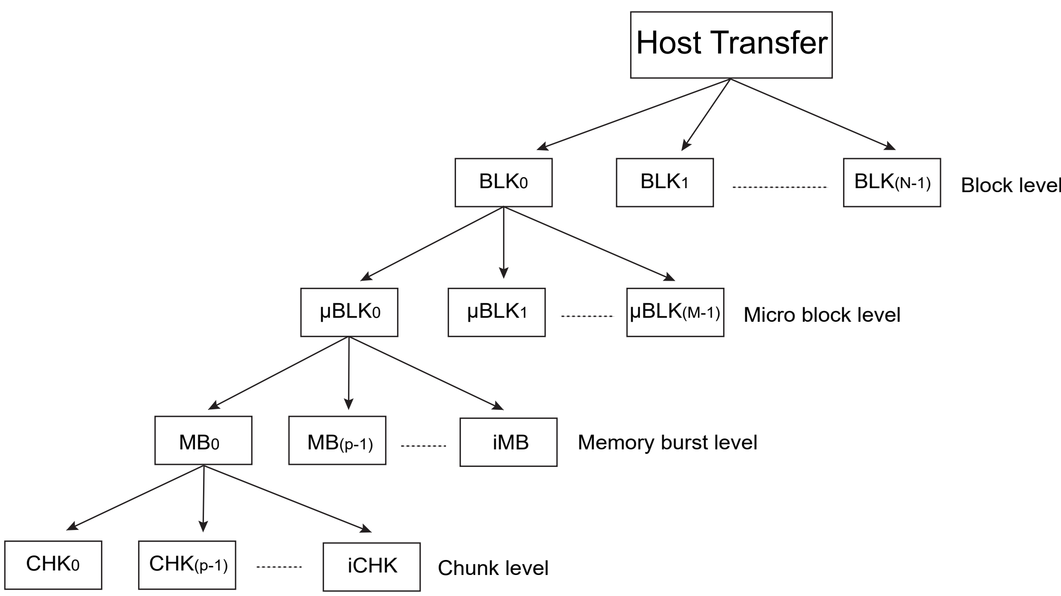
14.5.4 Peripheral Synchronized Transfer

A peripheral hardware request interface is used to control the pace of the chunk transfer. When a peripheral is ready to transmit or receive a chunk of data, it asserts its request line and the DMA Controller transfers a data to or from the memory to the peripheral.

14.5.4.1 Peripheral to Memory Transfer

XDMAC reads data from the source peripheral and writes to the destination memory location.

Figure 14-4. Peripheral to Memory Transfer Hierarchy



It is a peripheral synchronized transfer, which means the memory transaction is synchronized with the hardware trigger that comes from the corresponding peripheral. It is also possible to use software trigger to initiate data transfer. Peripheral to memory transfer has totally five levels of data transactions. They are Host, Block, Microblock, Burst, and Chunk level transactions. Host, Block, Microblock, and Burst level transactions work exactly the same way as explained earlier in the memory to memory data transfer section. In peripheral to memory data transfer, the burst level transaction is further split into chunk level data transaction to have higher granularity.

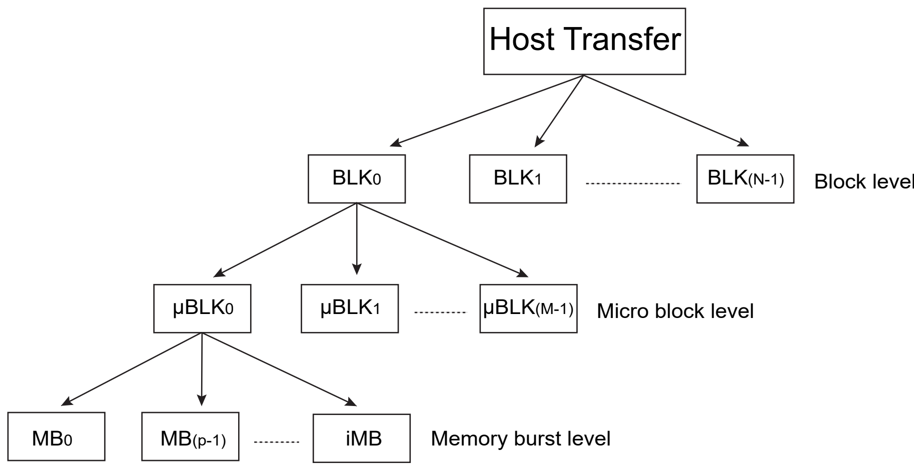
XDMAC Chunk and Incomplete Chunk: When a peripheral to memory transfer is activated, the burst level transaction is further split into a number of data chunks. The chunk size is configured in CSIZE field of XDMAC Channel Configuration Register (XDMAC_CCx). The chunk size denotes the number of 'data' to be transferred from the corresponding peripheral receive register to memory. In general, the chunk size is set as ‘1 data’ in most of the peripherals (example: - UART, SPI, TWI, etc.), as the maximum size of their receive register is ‘1 data’. In specific scenarios, the chunk size is chosen more than 1 data. For example, the data receive/input registers of AES and HSMCI modules can hold more than ‘1 data’. So, the chunk size can be chosen as '2/4/8/16 data' accordingly. In this case, the larger the chunk size is, the better the performance is. When the amount of data chunks read becomes equal to the memory burst size, the actual data transaction starts (as a memory burst). During ‘peripheral to memory’ transfer, the data chunks are first read and stored into XDMAC's internal FIFO buffer. If their size becomes equal to the memory burst size, the FIFO buffer gets flushed out automatically, which makes ‘memory burst transfer’. When the microblock size is not a multiple of the chunk size, the last chunk being transferred contains the last trailing data.

Note: If the chunk size is chosen as more than '1 data' for peripherals like UART, SPI, TWI, etc., XDMAC reads the same data register (receive/input register) multiple times. As a result, multiple copies of the same data are stored in the memory.

14.5.4.2 Memory to Peripheral Transfer

XDMAC reads data from source memory location and writes to the destination peripheral.

Figure 14-5. Memory to Peripheral Transfer Hierarchy



Memory to Peripheral transfer is also a peripheral synchronized transfer. It has totally four levels of data transactions. They are Host, Block, Microblock, and Chunk level transactions. Host, Block, and Microblock level transactions work exactly the same way as explained earlier in the memory to memory data transfer section. In memory to peripheral data transfer, the burst level transaction is not present. The microblock is directly split into chunk level data transaction.

XDMAC Chunk and Incomplete Chunk: When a memory to peripheral transfer is activated, the microblock level transaction is directly split into a number of data chunks. The chunk size is configured in CSIZE field of XDMAC Channel Configuration Register (XDMAC_CCx). The chunk size denotes the number of ‘data’ to be transferred from memory to the corresponding peripheral transmit register. In general, the chunk size is set as ‘1 data’ in most of the peripherals (example: - UART, SPI, TWI, etc.), as the maximum size of their transmit register is ‘1 data’. In specific scenarios, the chunk size is chosen more than 1 data. For example, the data transmit/output registers of AES and HSMCI modules can hold more than ‘1 data’. So, the chunk size can be chosen as '2/4/8/16 data' accordingly. In this case, the larger the chunk size is, the better the performance is. During ‘memory to peripheral’ transfer, the data chunks are immediately transferred when there is a hardware/software trigger. Memory burst size doesn't play any role here. When the microblock size is not a multiple of the chunk size, the last chunk being transferred contains the last trailing data.

Note: In case if the chunk size is chosen as more than '1 data' for peripherals like UART, SPI, TWI, etc., then XDMAC will overwrite the same data register (transmit/output register) with multiple data. As a result, only the last data gets transmitted.

14.5.4.3 Software Triggered Synchronized Transfer

The Peripheral hardware request can be software controlled using the SWREQ field of the XDMAC Global Channel Software Request Register (XDMAC_GSWR). The peripheral synchronized transfer is paced using a processor write access in the XDMAC_GSWR. Each bit of that register triggers a transfer request. The XDMAC Global Channel

Software Request Status Register (XDMAC_GSWS) indicates the status of the request; when set, the request is still pending.

14.5.5 XDMAC Transfer Software Operation

Note: When performing a memory-to-memory transfer, configure the field XDMAC_CCx.PERID (where 'x' is the index of the channel used for the transfer) to 0x7F.

14.5.5.1 Single Block Transfer With Single Microblock

1. Read the XDMAC Global Channel Status Register (XDMAC_GS) to select a free channel.
2. Clear the pending Interrupt Status bit(s) by reading the selected XDMAC Channel x Interrupt Status Register (XDMAC_CISx).
3. Write the XDMAC Channel x Source Address Register (XDMAC_CSAx) for channel x.
4. Write the XDMAC Channel x Destination Address Register (XDMAC_CDAx) for channel x.
5. Program field UBLEN in the XDMAC Channel x Microblock Control Register (XDMAC_CUBCx) with the number of data.
6. Program the XDMAC Channel x Configuration Register (XDMAC_CCx):
   a. Clear XDMAC_CCx.TYPE for a memory-to-memory transfer, otherwise set this bit.
   b. Configure XDMAC_CCx.MBSIZE to the memory burst size used.
   c. Configure XDMAC_CCx.SAM and DAM to Memory Addressing mode.
   d. Configure XDMAC_CCx.DSYNC to select the peripheral transfer direction.
   e. Set XDMAC_CCx.PROT to activate a secure channel.
   f. Configure XDMAC_CCx.CSIZE to configure the channel chunk size (only relevant for peripheral synchronized transfer).
   g. Configure XDMAC_CCx.DWIDTH to configure the transfer data width.
   h. Configure XDMAC_CCx.PERID to select the active hardware request line (only relevant for a peripheral synchronized transfer).
   i. Set XDMAC_CCx.SWREQ to use a software request (only relevant for a peripheral synchronized transfer).
7. Clear the following five registers:
   – XDMAC Channel x Next Descriptor Control Register (XDMAC_CNDCx)
   – XDMAC Channel x Block Control Register (XDMAC_CBCx)
   – XDMAC Channel x Data Stride Memory Set Pattern Register (XDMAC_CDS_MSPx)
   – XDMAC Channel x Source Microblock Stride Register (XDMAC_CSUSx)
   – XDMAC Channel x Destination Microblock Stride Register (XDMAC_CDUSx)
   This indicates that the linked list is disabled, there is only one block and striding is disabled.
8. Enable the Microblock interrupt by writing a '1' to bit BIE in the XDMAC Channel x Interrupt Enable Register (XDMAC_CIEx). Enable the Channel x Interrupt Enable bit by writing a '1' to bit IEx in the XDMAC Global Interrupt Enable Register (XDMAC_GIE).
9. Enable channel x by writing a '1' to bit ENx in the XDMAC Global Channel Enable Register (XDMAC_GE). XDMAC_GS.STx (XDMAC Channel x Status bit) is set by hardware.
10. Once completed, the DMA channel sets XDMAC_CISx.BIS (End of Block Interrupt Status bit) and generates an interrupt. XDMAC_GS.STx is cleared by hardware. The software can either wait for an interrupt or poll the channel status bit.

14.5.5.2 Single Block Transfer With Multiple Microblock

1. Read the XDMAC_GS register to choose a free channel.
2. Clear the pending Interrupt Status bit by reading the chosen XDMAC_CISx register.
3. Write the XDMAC_CSAx register for channel x.
4. Write the XDMAC_CDAx register for channel x.
5. Program XDMAC_CUBCx.UBLEN with the number of data.
6. Program XDMAC_CCx register (see "Single Block Transfer With Single Microblock").
7. Program XDMAC_CBCx.BLEN with the number of microblocks of data.
8. Clear the following registers:

   – XDMAC_CNDCx
   – XDMAC_CDS_MSPx
   – XDMAC_CSUSx XDMAC_CDUSx
     This indicates that the linked list is disabled and striding is disabled.
9. Enable the Block interrupt by writing a ‘1’ to XDMAC_CIEx.BIE, enable the Channel x Interrupt Enable bit by writing a ‘1’ to XDMAC_GIEx.IEx.
10. Enable channel x by writing a ‘1’ to the XDMAC_GE.ENx. XDMAC_GS.STx is set by hardware.
11. Once completed, the DMA channel sets XDMAC_CISx.BIS (End of Block Interrupt Status bit) and generates an interrupt. XDMAC_GS.STx is cleared by hardware. The software can either wait for an interrupt or poll the channel status bit.

14.5.5.3 Host Transfer

1. Read the XDMAC_GS register to choose a free channel.
2. Clear the pending Interrupt Status bit by reading the chosen XDMAC_CISx register.
3. Build a linked list of transfer descriptors in memory. The descriptor view is programmable on a per descriptor basis. The linked list items structure must be word aligned. MBR_UBC.NDE must be configured to 0 in the last descriptor to terminate the list.
4. Configure field NDA in the XDMAC Channel x Next Descriptor Address Register (XDMAC_CNDAx) with the first descriptor address .
5. Configure the XDMAC_CNDCx register:
   a. Set XDMAC_CNDCx.NDE to enable the descriptor fetch.
   b. Set XDMAC_CNDCx.NDSUP to update the source address at the descriptor fetch time, otherwise clear this bit.
   c. Set XDMAC_CNDCx.NDDUP to update the destination address at the descriptor fetch time, otherwise clear this bit.
   d. Configure XDMAC_CNDCx.NDVIEW to define the length of the first descriptor.
6. Enable the End of Linked List interrupt by writing a ‘1’ to XDMAC_CIEx.LIE.
7. Enable channel x by writing a ‘1’ to XDMAC_GE.ENx. XDMAC_GS.STx is set by hardware.
8. Once completed, the DMA channel sets XDMAC_CISx.BIS (End of Block Interrupt Status bit) and generates an interrupt. XDMAC_GS.STx is cleared by hardware. The software can either wait for an interrupt or poll the channel status bit.

14.5.5.4 Disabling A Channel Before Transfer Completion

Under normal operation, the software enables a channel by writing a ‘1’ to XDMAC_GE.ENx, then the hardware disables a channel on transfer completion by clearing bit XDMAC_GS.STx. To disable a channel, write a ‘1’ to bit XDMAC_GD.DIx and poll the XDMAC_GS register.

14.6 Linked List Descriptor Operation

Bit	7	6	5	4	3	2	1	0
	UBLEN[7:0]							
Access	R	R	R	R	R	R	R	R
Reset								

Bits 30:29 – QOS[1:0] Channel Quality of Service Level
This field indicates the current quality of service level for the channel. Refer to the section “MATRIX”.

Bits 28:27 – NVIEW[1:0] Next Descriptor View

Value	Name	Description
0	NDV0	Next Descriptor View 0
1	NDV1	Next Descriptor View 1
2	NDV2	Next Descriptor View 2
3	NDV3	Next Descriptor View 3

Bit 26 – NDEN Next Descriptor Destination Update

Value	Description
0	Destination parameters remain unchanged.
1	Destination parameters are updated when the descriptor is retrieved.

Bit 25 – NSEN Next Descriptor Source Update

Value	Description
0	Source parameters remain unchanged.
1	Source parameters are updated when the descriptor is retrieved.

Bit 24 – NDE Next Descriptor Enable

Value	Description
0	Descriptor fetch is disabled.
1	Descriptor fetch is enabled.

Bits 23:0 – UBLEN[23:0] Microblock Length
This field indicates the number of data in the microblock. The microblock contains UBLEN data.

14.7 XDMAC Maintenance Software Operations

14.7.1 Disabling a Channel

A disable channel request occurs when a write operation is performed in the XDMAC_GD register. If the channel is source peripheral synchronized (bit XDMAC_CCx.TYPE is set and bit XDMAC_CCx.DSYNC is cleared), then pending bytes (bytes located in the FIFO) are written to memory and bit XDMAC_CISx.DIS is set. If the channel is not source peripheral synchronized, the current channel transaction (read or write) is terminated and XDMAC_CISx.DIS is set. XDMAC_GS.STx is cleared by hardware when the current transfer is completed. The channel is no longer active and can be reused.

14.7.2 Suspending a Channel

A disable channel request occurs when a write operation is performed in the XDMAC_GD register. If the channel is source peripheral synchronized (bit XDMAC_CCx.TYPE is set and bit XDMAC_CCx.DSYNC is cleared), then pending bytes (bytes located in the FIFO) are written to memory and bit XDMAC_CISx.DIS is set. If the channel is not source peripheral synchronized, the current channel transaction (read or write) is terminated and XDMAC_CISx.DIS is set. XDMAC_GS.STx is cleared by hardware when the current transfer is completed. The channel is no longer active and can be reused.

14.7.3 Flushing a Channel

A FIFO flush command is issued by writing to the XDMAC_SWF register. The content of the FIFO is written to memory. XDMAC_CISx.FIS (End of Flush Interrupt Status bit) is set when the last byte is successfully transferred to memory. The channel is not disabled. The flush operation is not blocking, meaning that read operation can be scheduled during the flush write operation. The flush operation is only relevant for peripheral to memory transfer where pending peripheral bytes are buffered into the channel FIFO.

14.7.4 Maintenance Operation Priority

14.7.4.1 Disable Operation Priority

- When a disable request occurs on a suspended channel, the XDMAC_GWS.WSx (Channel x Write Suspend bit) is cleared. If the transfer is source peripheral synchronized, the pending bytes are drained to memory. The bit XDMAC_CISx.DIS is set.
- When a disable request follows a flush request, if the flush last transaction is not yet scheduled, the flush request is discarded and the disable procedure is applied. Bit XDMAC_CISx.FIS is not set. Bit XDMAC_CISx.DIS is set when the disable request is completed. If the flush request transaction is already scheduled, the XDMAC_CISx.FIS is set. XDMAC_CISx.DIS is also set when the disable request is completed.

14.7.4.2 Flush Operation Priority

- When a flush request occurs on a suspended channel, if there are pending bytes in the FIFO, they are written out to memory, XDMAC_CISx.FIS is set. If the FIFO is empty, XDMAC_CISx.FIS is also set.
- If the flush operation is performed after a disable request, the flush command is ignored. XDMAC_CISx.FIS is not set.

14.7.4.3 Suspend Operation Priority

If the suspend operation is performed after a disable request, the write suspend operation is ignored.

14.8 XDMAC Software Requirements

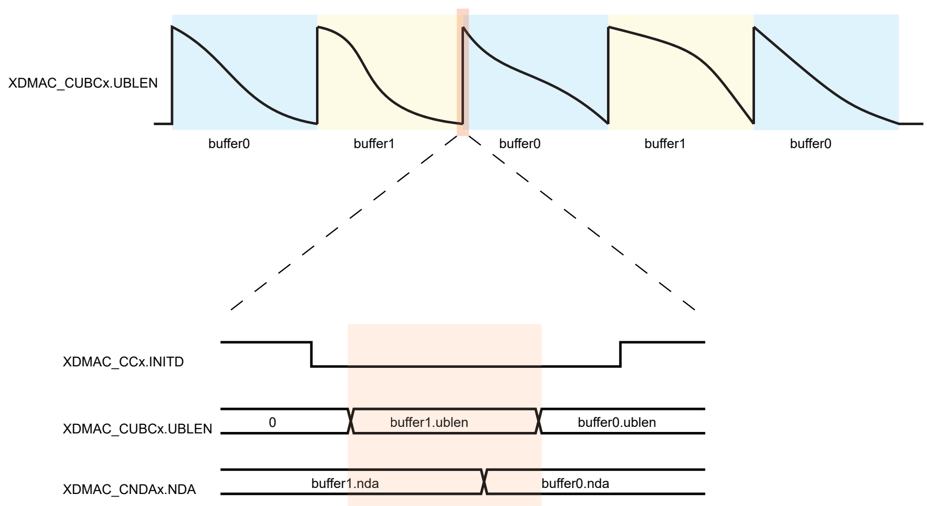
- Write operations to channel registers are not be performed in an active channel after the channel is enabled. If any channel parameters must be reprogrammed, this can only be done after disabling the XDMAC channel.
- XDMAC_CSAx and XDMAC_CDAx channel registers must be programmed with a byte, half-word, word or double-word aligned address depending on the Channel x Data Width field (DWIDTH) of the XDMAC Channel x Configuration Register. When a memory-to-peripheral transfer is performed, the XDMAC_CSAx address register has no alignment requirement.
- When a memory-to-memory transfer is performed, configure the field XDMAC_CCx.PERID (where ‘x’ is the index of the channel used for the transfer) to peripheral ID 127 (refer to the table “Peripheral Identifiers”).

- When XDMAC_CC.INITD is set to 0, XDMAC_CUBC.UBLEN and XDMAC_CNDA.NDA field values are unreliable when the descriptor is being updated. The following procedure applies to get the buffer descriptor identifier and the residual bytes:

```
Read XDMAC_CNDAx.NDA(nda0)
Read XDMAC_CCx.INITD(initd0)
Read XDMAC_CCx.INITD(initd0)
Read XDMAC_CUBCx.UBLEN(ublen)
Read XDMAC_CCx.INITD(initd1)
Read XDMA_CNDAx.NDA(nda1)
If (nda0 == nda1 && initd0 == 1 && initd1 == 1).
Then the ublen is correct, the buffer id is nda.
Else retry
```

  See the figure below.
- Each DMA channel can be configured in either Secure or Non-secure mode independently. When a DMA channel is secure, its related global register fields and its channel registers cannot be modified nor read by non-secure software. Such non-secure reads return zero.

Figure 14-6. INITD Timing Diagram



14.9 Register Summary

Offset	Name	Bit Pos.	7	6	5	4	3	2	1	0
0x00	XDMAC_GTYPE	31:24								
		23:16		NB_REQ[6:0]

14.9.1 XDMAC Global Type Register

Name: XDMAC_GTYPE
Offset: 0x00
Property: Read-only

Reset: The register reset values depend on the instance of the XDMAC:

Instance	Reset Value
XDMAC0, XDMAC1	0x004A201F
XDMAC2	0x00020007

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
		NB_REQ[6:0]						
Access		R	R	R	R	R	R	R
Reset								

Bit	15	14	13	12	11	10	9	8
	FIFO_SZ[10:3]							
Access	R	R	R	R	R	R	R	R
Reset								

Bit	7	6	5	4	3	2	1	0
	FIFO_SZ[2:0]			NB_CH[4:0]				
Access	R	R	R	R	R	R	R	R
Reset								

Bits 22:16 – NB_REQ[6:0] Number of Peripheral Requests Minus One

Bits 15:5 – FIFO_SZ[10:0] Number of Bytes
The FIFO size is given by the formula: Number of bytes + 8.

Bits 4:0 – NB_CH[4:0] Number of Channels Minus One

14.9.2 XDMAC Global Configuration Register

Name: XDMAC_GCFG
Offset: 0x04
Reset: 0x00000000
Property: Read/Write

Notes:
1. WRxP fields: to maximize system performance and avoid system head of line blocking, verify that (WRHP+1)+(WRMP+1)+(WRLP+1) is less than or equal to the system buffering capability (i.e., the size of addresses and write data buffer in the system bus interconnect).
2. RDSG/RDxP fields: to maximize system performance and avoid system head of line blocking, verify that (RDSG+1)(RDHP+1)(RDMP+1)+(RDLP+1) is less than or equal to the system read buffering capability (i.e., the size of addresses buffer in the system bus interconnect).
3. WRxP, RDSG, RDxP fields are related to the RAQ and WAQ DDR queues, defined respectively in “Read Address Channel” and “Write Address Channel” in the section “Universal DDR Memory Controller (UDDRC)”.

Bit	31	30	29	28	27	26	25	24
	RDSG[3:0]				RDLP[3:0]			
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	RDMP[3:0]				RDHP[3:0]			
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	WRLP[3:0]				WRMP[3:0]			
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	WRHP[3:0]				CGDISIF	CGDISFIFO	CGDISPIPE	CGDISREG
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 31:28 – RDSG[3:0] Read Queue Scatter Gather Outstanding Limit
RDSG+1 is the maximum number of active transactions for descriptor read access.

Bits 27:24 – RDLP[3:0] Read Queue Low Priority Outstanding Limit
RDLP+1 is the maximum number of active transactions for read access (memory) of a memory-to-memory transfer.

Bits 23:20 – RDMP[3:0] Read Queue Medium Priority Outstanding Limit
RDMP+1 is the maximum number of active transactions for read access (memory) of a memory-to-peripheral transfer.

Bits 19:16 – RDHP[3:0] Read Queue High Priority Outstanding Limit
RDHP+1 is the maximum number of active transactions for read access (peripheral) of a peripheral-to-memory transfer.

Bits 15:12 – WRLP[3:0] Write Queue Low Priority Outstanding Limit
WRLP+1 is the maximum number of active transactions for write access (memory) of a memory-to-memory transfer.

Bits 11:8 – WRMP[3:0] Write Queue Medium Priority Outstanding Limit
WRMP+1 is the maximum number of active transactions for write access (memory) of peripheral-to-memory transfer.

Bits 7:4 – WRHP[3:0] Write Queue High Priority Outstanding Limit
WRHP+1 is the maximum number of active transactions for write access (peripheral) of a memory-to-peripheral transfer.

Bit 3 – CGDISIF Bus Interface Clock Gating Disable

Value	Description
0	The automatic clock gating is enabled for the system bus interface.
1	The automatic clock gating is disabled for the system bus interface.

Bit 2 – CGDISFIFO FIFO Clock Gating Disable

Value	Description
0	The automatic clock gating is enabled for the main FIFO.
1	The automatic clock gating is disabled for the main FIFO.

Bit 1 – CGDISPIPE Pipeline Clock Gating Disable

Value	Description
0	The automatic clock gating is enabled for the main pipeline.
1	The automatic clock gating is disabled for the main pipeline.

Bit 0 – CGDISREG Configuration Registers Clock Gating Disable

Value	Description
0	The automatic clock gating is enabled for the configuration registers.
1	The automatic clock gating is disabled for the configuration registers.

14.9.3 XDMAC Global Weighted Arbiter Configuration Register

Name: XDMAC_GWAC
Offset: 0x08
Reset: 0x00000000
Property: Read/Write

Notes:

1. PW0/1: when a memory-to-peripheral transaction occurs, the peripheral write transaction may be asserted at the same time as a memory write transaction. The write port arbiter grants bus access to the highest transaction weight first, then the internal weight counter is decremented. When the internal weight counter reaches 0, it is reloaded with PWx. If PW0=0 and PW1 = 0, the arbitration method is round-robin.
2. PW2/3: When a peripheral-to-memory transaction occurs, the peripheral read transaction may be asserted at the same time as a memory read transaction. The Read Port Arbiter grants bus access to the highest transaction weight first, then the internal weight counter is decremented. When the internal weight counter reaches 0, it is reloaded with PWx. If PW2=0 and PW3 = 0, the arbitration method is round-robin.

Bit	31	30	29	28	27	26	25	24

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 15:12 – PW3[3:0] Pool Weight 3
Memory transaction weight for read port arbiter. This is exactly the peripheral read transaction weight of a memory-tomemory transfer.

Bits 11:8 – PW2[3:0] Pool Weight 2
Peripheral transaction weight for read port arbiter. This is exactly the peripheral read transaction weight of a peripheral-tomemory transfer.

Bits 7:4 – PW1[3:0] Pool Weight 1
Memory transaction weight for write port arbiter. This is exactly the memory write transaction weight of a memory-to-memory transfer.

Bits 3:0 – PW0[3:0] Pool Weight 0
Peripheral transaction weight for write port arbiter. This is exactly the peripheral write transaction weight of a memory-to-peripheral transfer.

14.9.4 XDMAC Global Interrupt Enable Register

Value	Description
0	Overflow condition has not occurred.
1	Overflow condition has occurred at least once. (This information is only relevant for peripheral synchronized transfers.)

Bit 5 – WBEIS Write Bus Error Interrupt Status

Value	Description
0	Write bus error condition has not occurred.
1	At least one bus error has been detected in a write access since the last read of the Status register.

Bit 4 – RBEIS Read Bus Error Interrupt Status

Value	Description
0	Read bus error condition has not occurred.
1	At least one bus error has been detected in a read access since the last read of the Status register.

Bit 3 – FIS End of Flush Interrupt Status

Value	Description
0	End of flush condition has not occurred.
1	End of flush condition has occurred since the last read of the Status register.

Bit 2 – DIS End of Disable Interrupt Status

Value	Description
0	End of disable condition has not occurred.

Value	Description
1	End of disable condition has occurred since the last read of the Status register.

Bit 1 – LIS End of Linked List Interrupt Status

Value	Description
0	End of linked list condition has not occurred.
1	End of linked list condition has occurred since the last read of the Status register.

Bit 0 – BIS End of Block Interrupt Status

Value	Description
0	End of block interrupt has not occurred.
1	End of block interrupt has occurred since the last read of the Status register.

14.9.26 XDMAC Channel x Source Address Register [x = 0..31]

Name: XDMAC_CSA
Offset: 0x70 + n*0x40 [n=0..31]
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
	SA[31:24]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Reset		0	0	0	0	0	0	0

Bits 6:5 – QOS[1:0] Channel Quality Of Service level
This field indicates the current quality of service level for the channel. Refer to the section "MATRIX".

Bits 4:3 – NDVIEW[1:0] Channel x Next Descriptor View

Value	Name	Description
0	NDV0	Next Descriptor View 0
1	NDV1	Next Descriptor View 1
2	NDV2	Next Descriptor View 2
3	NDV3	Next Descriptor View 3

Bit 2 – NDDUP Channel x Next Descriptor Destination Update
0 (): .
1 ():

Value	Name	Description
0	DST_PARAMS_UNCHANGED	Destination parameters remain unchanged.
1	DST_PARAMS_UPDATED	Destination parameters are updated when the descriptor is retrieved.

Bit 1 – NDSUP Channel x Next Descriptor Source Update

Value	Name	Description
0	SRC_PARAMS_UNCHANGED	Source parameters remain unchanged.
1	SRC_PARAMS_UPDATED	Source parameters are updated when the descriptor is retrieved.

Bit 0 – NDE Channel x Next Descriptor Enable

Value	Name	Description
0	DSCR_FETCH_DIS	Descriptor fetch is disabled.
1	DSCR_FETCH_EN	Descriptor fetch is enabled.

14.9.30 XDMAC Channel x Microblock Control Register [x = 0..31]

Name: XDMAC_CUBC
Offset: 0x80 + n*0x40 [n=0..31]
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24

Access	R/W	R/W	R/W	R/W		R/W	R/W	R/W
Reset	0	0	0	0		0	0	0

Bits 30:24 – PERID[6:0] Channel x Peripheral Hardware Request Line Identifier
This field contains the peripheral hardware request line identifier. PERID refers to identifiers defined in "DMA Controller Peripheral Connections".
Note: When a memory-to-memory transfer is performed, configure PERID to 0x7F.

Bit 23 – WRIP Write in Progress

Value	Name	Description
0	DONE	No active write transaction on the bus.
1	IN_PROGRESS	A write transaction is in progress.

Bit 22 – RDIP Read in Progress

Value	Name	Description
0	DONE	No active read transaction on the bus.
1	IN_PROGRESS	A read transaction is in progress.

Bit 21 – INITD Channel Initialization Done
When set to 0, XDMAC_CUBC.UBLEN and XDMAC_CNDA.NDA field values are unreliable each time a descriptor is being updated. See 14.8. XDMAC Software Requirements.

Value	Name	Description
0	IN_PROGRESS	Channel initialization is in progress.
1	TERMINATED	Channel initialization is completed.

Bits 19:18 – DAM[1:0] Channel x Destination Addressing Mode

Value	Name	Description
0	FIXED_AM	The address remains unchanged.
1	INCREMENTED_AM	The addressing mode is incremented (the increment size is set to the data size).
2	UBS_AM	The microblock stride is added at the microblock boundary.
3	UBS_DS_AM	The microblock stride is added at the microblock boundary; the data stride is added at the data boundary.

Bits 17:16 – SAM[1:0] Channel x Source Addressing Mode

Value	Name	Description
0	FIXED_AM	The address remains unchanged.
1	INCREMENTED_AM	The addressing mode is incremented (the increment size is set to the data size).
2	UBS_AM	The microblock stride is added at the microblock boundary.
3	UBS_DS_AM	The microblock stride is added at the microblock boundary, the data stride is added at the data boundary.

Bits 12:11 – DWIDTH[1:0] Channel x Data Width

Value	Name	Description
0	BYTE	The data size is set to 8 bits
1	HALFWORD	The data size is set to 16 bits
2	WORD	The data size is set to 32 bits
3	DWORD	The data size is set to 64 bits

Bits 10:8 – CSIZE[2:0] Channel x Chunk Size

Value	Name	Description
0	CHK_1	1 data transferred
1	CHK_2	2 data transferred
2	CHK_4	4 data transferred
3	CHK_8	8 data transferred
4	CHK_16	16 data transferred

Bit 7 – MEMSET Channel x Fill Block of Memory

Value	Name	Description
0	NORMAL_MODE	Memset is not activated.
1	HW_MODE	Sets the block of memory pointed by DA field to the specified value. This operation is performed on 8-, 16- or 32-bit basis.

Bit 6 – SWREQ Channel x Software Request Trigger

Value	Name	Description
0	HWR_CONNECTED	Hardware request line is connected to the peripheral request line.
1	SWR_CONNECTED	Software request is connected to the peripheral request line.

Bit 5 – PROT Channel x Protection

When a descriptor is loaded, the PROT bit cannot be modified. If PROT=0 for a channel, the configuration and status registers of this channel cannot be modified by unsecure software.

Value	Name	Description
0	SEC	Channel is secured.
1	UNSEC	Channel is unsecured.

Bit 4 – DSYNC Channel x Synchronization

Value	Name	Description
0	PER2MEM	Peripheral-to-memory transfer
1	MEM2PER	Memory-to-peripheral transfer

Bits 2:1 – MBSIZE[1:0] Channel x Memory Burst Size

Value	Name	Description
0	SINGLE	The memory burst size is set to one.
1	FOUR	The memory burst size is set to four.
2	EIGHT	The memory burst size is set to eight.
3	SIXTEEN	The memory burst size is set to sixteen.

Bit 0 – TYPE Channel x Transfer Type

Value	Name	Description
0	MEM_TRAN	Self-triggered mode (memory-to-memory transfer)
1	PER_TRAN	Synchronized mode (peripheral-to-memory or memory-to-peripheral transfer)

14.9.33 XDMAC Channel x Data Stride Memory Set Pattern Register [x = 0..31]

Name: XDMAC_CDS_MSP
Offset: 0x8C + n*0x40 [n=0..31]
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
	DDS_MSP[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	DDS_MSP[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	SDS_MSP[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	SDS_MSP[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 31:16 – DDS_MSP[15:0] Channel x Destination Data Stride or Memory Set Pattern
When XDMAC_CCx.MEMSET = 0, this field indicates the destination data stride.
Number of bytes for the data stride of channel x (two's complement). If the field is set to zero the data is contiguous (see Data Striding Diagram).
The DDS_MSP field is only relevant when XDMAC_CCx.SAM=UBS_DS_AM.
When XDMAC_CCx.MEMSET = 1, this field indicates the memory set pattern.

Bits 15:0 – SDS_MSP[15:0] Channel x Source Data Stride or Memory Set Pattern
When XDMAC_CCx.MEMSET = 0, this field indicates the source data stride.
Number of bytes for the data stride of channel x (two's complement). If the field is set to zero the data is contiguous (see Data Striding Diagram).
The SDS_MSP field is only relevant when XDMAC_CCx.SAM=UBS_DS_AM.
When XDMAC_CCx.MEMSET = 1, this field indicates the memory set pattern.

14.9.34 XDMAC Channel x Source Microblock Stride Register [x = 0..31]

Name: XDMAC_CSUS
Offset: 0x90 + n*0x40 [n=0..31]
Reset: 0x00000000
Property: Read/Write

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 23:0 – SUBS[23:0] Channel x Source Microblock Stride
Number of bytes for the microblock stride for channel x (two's complement). If the field is set to zero the data is contiguous (see Figure 14-2).
The SUBS field is only relevant when XDMAC_CCx.SAM=UBS_AM or XDMAC_CCx.SAM=UBS_DS_AM.

14.9.35 XDMAC Channel x Destination Microblock Stride Register [x = 0..31]

Name: XDMAC_CDUS
Offset: 0x94 + n*0x40 [n=0..31]

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 23:0 – DUBS[23:0] Channel x Destination Microblock Stride
Number of bytes for the microblock stride for channel x (two's complement). If the field is set to zero the data is contiguous (see Figure 14-2).
The DUBS field is only relevant when XDMAC_CCx.SAM=UBS_AM or XDMAC_CCx.SAM=UBS_DS_AM.

14.9.36 XDMAC Channel x Transfer Count Status Register [x = 0..XDMAC_NB_CH-131]

Name: XDMAC_CTCS
Offset: 0x98 + n*0x40 [n=0..31]
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access

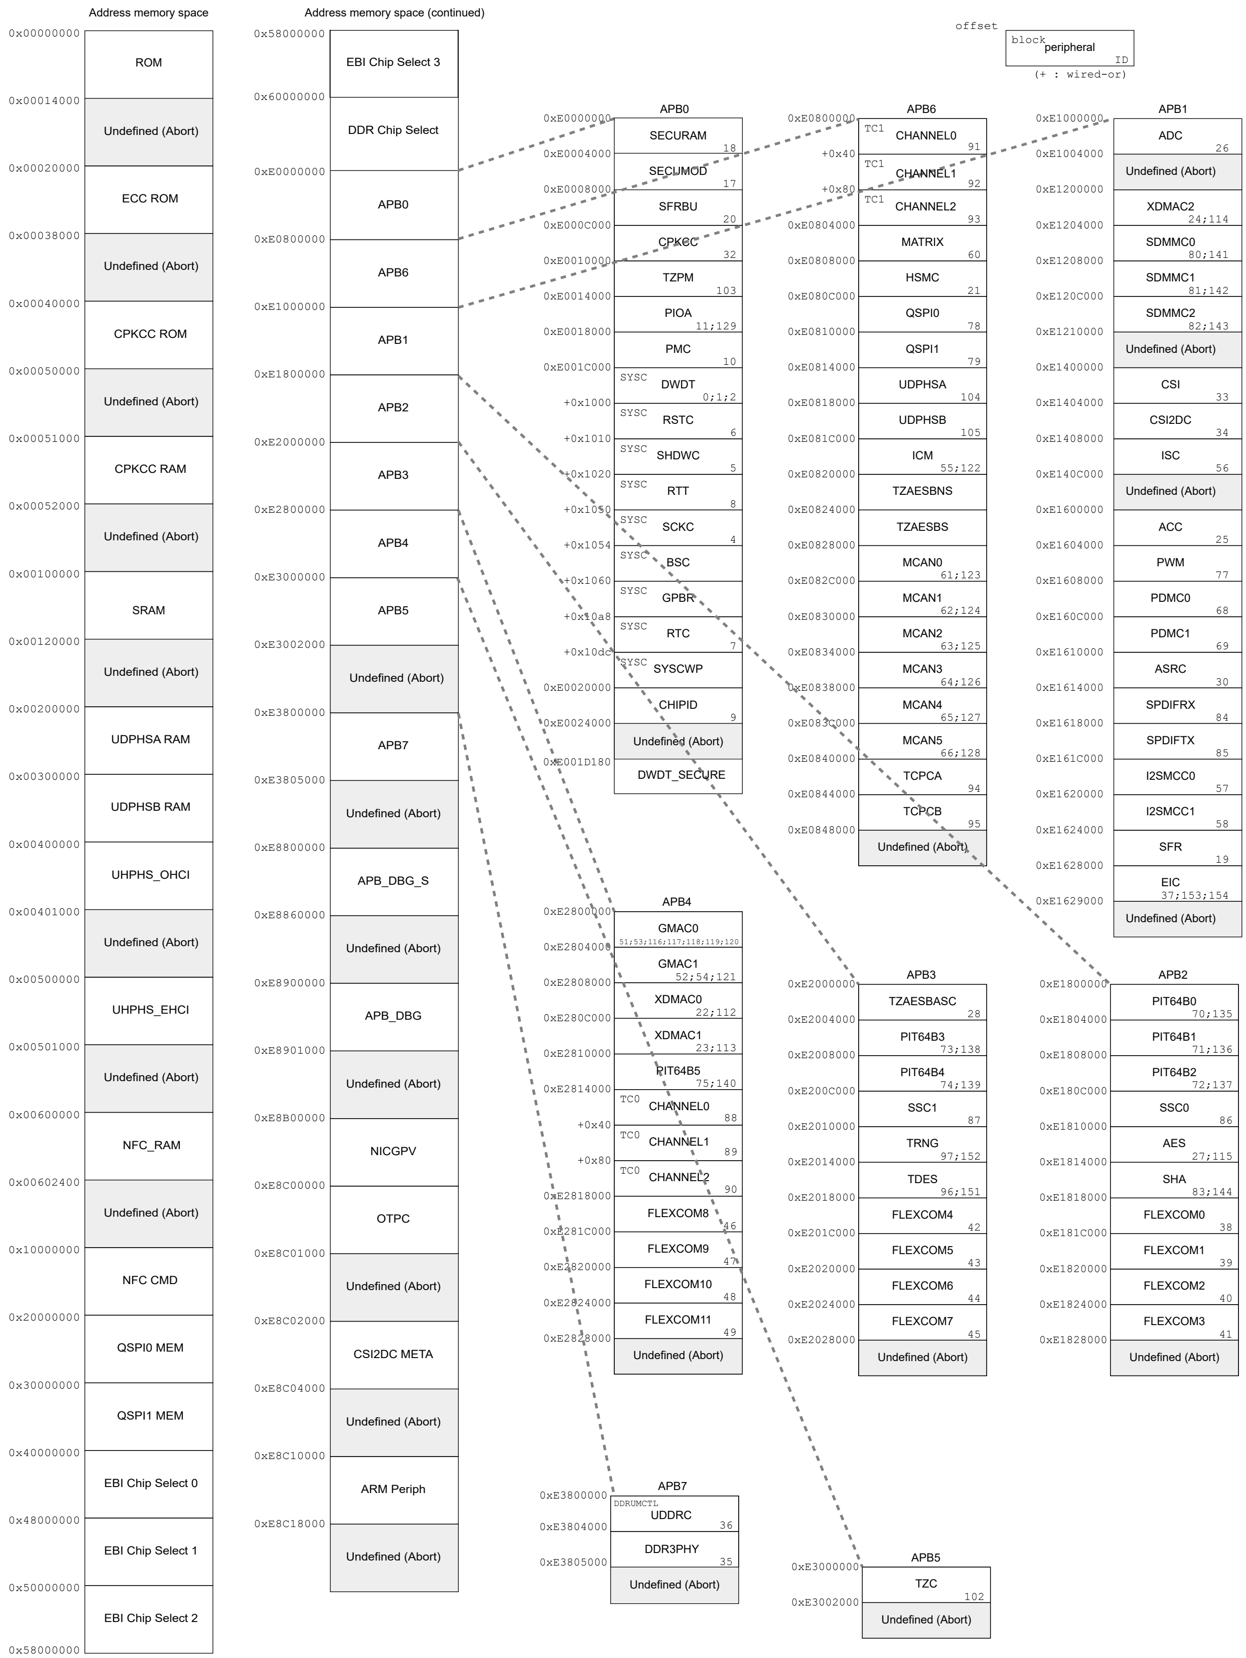
	TC[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 23:0 – TC[23:0] Channel x Transfer Count
Number of bytes written by the XDMA since the last read of the Transfer Count Status register. The field does not indicate the number of bytes written to memory.
To get the number of bytes already written in memory at any time during peripheral-to-memory transfer, use the following software procedure:

1. Read the XDMAC_CTCSx.TC field to sample the number of bytes received by the XDMA.
2. Perform a software flush of the channel by writing one to the XDMAC_GSWF register. This will push bytes from the internal DMA FIFO to the external memory and return an interrupt when the bytes can be read by the CPU.

15. MEMORIES

Figure 15-1. Memory Mapping



15.1 Embedded Memories

15.1.1 Internal SRAM

The device embeds a total of 128 Kbytes of high-speed SRAM. The SRAM is always accessible at address 0x00100000.

The device embeds 5 Kbytes of SRAM (SECURAM) always accessible at address 0xE0000000. The SECURAM is used by OTPC and SECUMOD.

15.1.2 Internal ROM

The ROM contents are:

- ROM0: Secure bootloader (80 Kbytes) at offset 0
- ROM1: BCH tables to compute NAND Flash ECC (96 Kbytes) at address 0X00002000
- ROM2: Crypto-libraries CPKCC (40 Kbytes) at address 0X00040000

By construction, ROMs are only accessible by the CPU with the restriction below:

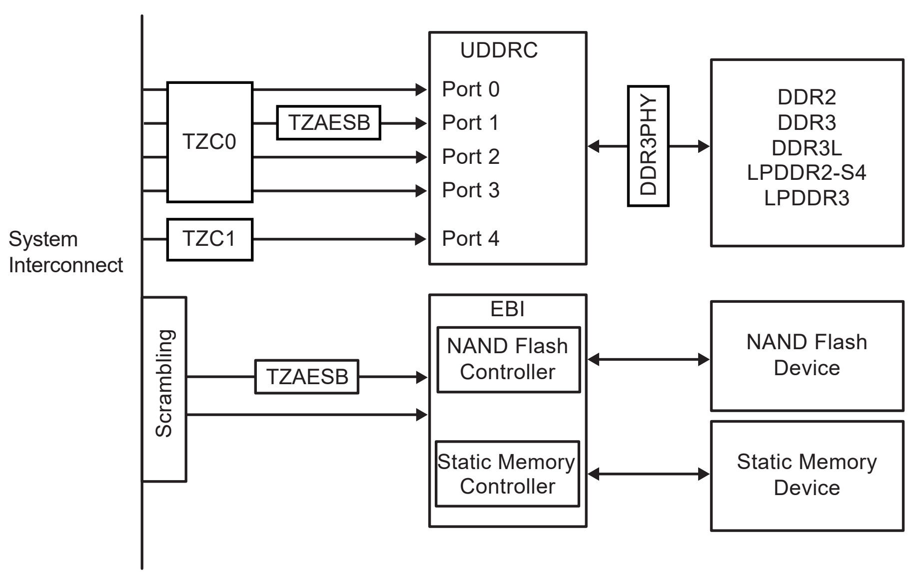
- ROM0: accessible only in Secure mode and when executed after reset. This memory is hidden before running code in internal SRAM.
- ROM1: always accessible in Secure and Non-secure modes
- ROM2: always accessible in Secure mode

15.2 External Memories

The device features:

- A Universal DDR-SDRAM Controller (UDDRC), supporting DDR2, DDR3, DDR3L, LPDDR2-S4 and LPDDR3 devices.
- An External Bus Interface (EBI) that embeds a NAND Flash controller and a Static Memory Controller (HSMC). The HSMC supports Static Memories and MLC/SLC NAND Flash. It embeds MultiBit ECC correction (PMECC). The HSMC buses can be scrambled and can be connected to an AES encryption/decryption engine.

Figure 15-2. External Memory Controllers



For more details, refer to I/O AC Characteristics and System Interconnect and Security (SIS).

15.2.1 Universal DDR-SDRAM Controller (UDDRC)

The UDDRC is a 5-port memory controller supporting DDR-SDRAM and low-power DDR devices. Data transfers are performed through a 16-bit data bus on one chip select. The memory interface operates with a 1.8V power supply for DDR2, 1.5V for DDR3, 1.35V for DDR3L, and 1.2V for LPDDR2 and LPDDR3.

For full details, refer to the sections Universal DDR-SDRAM Controller (UDDRC) and DDR/LPDDR Physical Interface (DDR3PHY).

15.2.2 External Bus Interface (EBI)

The External Bus Interface is designed to ensure the successful data transfer between several external devices and the processor. The EBI of the device consists of a Static Memory Controller (SMC) and a NAND Flash Controller (NFC).

For full details, refer to the section Static Memory Controller (SMC).

15.2.2.1 Description

The External Bus Interface is designed to ensure the successful data transfer between several external devices and the Arm processor-based device. The device EBI consists of a Static Memory Controller (SMC).

15.3 Product Dependencies

15.3.1 Clocks

Memory clocks are not controlled by the PMC.

- ROM and CPKCC are on the CPU System and Security (CSS) matrix and therefore clocked by MCK0.
- SECURAM is located on CSS and clocked by MCK0 divided by 32.
- SRAM, SMC and NFC_RAM are located on the AHB System (HSS) matrix, clocked by MCK1.
- UDDRC and DDR3PHY are clocked by MCK2 and hard-wired to the DDRPLLCK.

Note: The MCK0 frequency is directly related to the CPU clock, so any change on the CPU clock impacts MCK0.

⚠ CAUTION MCK3 must be started during UDDRC and DDR3PHY initialization.

15.3.2 Interrupts

Refer to the table Peripheral Identifiers.

15.3.3 Reset

SMC and NFC are connected to the processor and peripherals reset line.

UDDRC and DDR3PHY have separated reset lines, controlled in RSTC_ GRSTR.

15.3.4 I/Os

DDR-SDRAM I/Os are high-speed specific I/Os powered by VDDIODDR. These can be programmed in Retention state in order to maintain their state in Backup Self-refresh mode.

15.4 Special Functions in SFR/SFRBU

- SFR_UDDRC.DIS_DECERR, to be set during the debug phase to avoid UDDRC decode errors with the debugger
- SFRBU_DDRPWR.RETENTION to control DDR-SDRAM I/O Retention state

16. Static Memory Controller (SMC)

16.1 Description

This Static Memory Controller (SMC) is capable of handling several types of external memory and peripheral devices, such as SRAM, PSRAM, PROM, EPROM, EEPROM, LCD Module, NOR Flash and NAND Flash.

The SMC generates the signals that control the access to external memory devices or peripheral devices. It has 4 Chip Selects and a 26-bit address bus. The 16-bit data bus can be configured to interface with 8- or 16-bit external devices. Separate read and write control signals allow for direct memory and peripheral interfacing. Read and write signal waveforms are fully configurable.

The SMC can manage wait requests from external devices to extend the current access. The SMC is provided with an automatic Slow Clock mode. In Slow Clock mode, it switches from user-programmed waveforms to slow-rate specific waveforms on read and write signals.

The SMC embeds a NAND Flash Controller (NFC). The NFC can handle automatic transfers, sending the commands and address cycles to the NAND Flash and transferring the contents of the page (for read and write) to the NFC SRAM. It minimizes the CPU overhead.

The SMC embeds a programmable binary BCH encoder/decoder that generates redundancy information at encoding for both SLC and MLC NAND devices. It supports redundancy for correction of 2, 4, 8, 12, 24, or 32 errors per sector of 512 or 1024 bytes.

The External Data Bus can be scrambled/unscrambled by means of user keys.

16.2 Embedded Characteristics

- 128-Mbyte Address Space per Chip Select
- 8- or 16-bit Data Bus
- Word, Halfword, Byte Transfers
- Byte Write or Byte Select Lines
- Programmable Setup, Pulse and Hold Time for Read Signals per Chip Select
- Programmable Setup, Pulse and Hold Time for Write Signals per Chip Select
- Programmable Data Float Time per Chip Select
- External Data Bus Scrambling/Unscrambling Function
- External Wait Request
- Automatic Switch to Slow Clock Mode
- Hardware Configurable Number of Chip Selects from 1 to 4
- Programmable Timing on a per Chip Select Basis
- NAND Flash Controller Supporting NAND Flash with Multiplexed Data/Address Buses
- Supports SLC and MLC NAND Flash Technology
- Supports NAND Flash Devices with 8 or 16-bit Data Paths
- Multibit Error Correcting Code (ECC) supporting NAND Flash devices with 8-bit only Data Path
- ECC Algorithm Based on Binary Shortened Bose, Chaudhuri and Hocquenghem (BCH) Codes
- Programmable Error Correcting Capability: 2, 4, 8, 12, 24 and 32 bits of Errors per Block
- 9 Kbytes NFC SRAM (NFC_RAM)
- Programmable Block Size: 512 bytes or 1024 bytes
- Programmable Number of Blocks per Page: 1, 2, 4 or 8 Blocks of Data per Page
- Programmable Spare Area Size up to 512 bytes
- Supports Spare Area ECC Protection
- Supports 8 Kbytes Page Size Using 1024 bytes/block and 4 Kbytes Page Size Using 512 bytes/block
- Multibit Error Detection Is Interrupt Driven

- Provides Hardware Acceleration for Determining Roots of Polynomials Defined over a Finite Field
- Programmable Finite Field GF(2^13) or GF(2^14)
- Finds Roots of Error-locator Polynomial
- Programmable Number of Roots
- Register Write Protection

Name	Description	Type	Active Level
NANDCLE	NAND Flash Command Latch Enable	Output	–

16.5 Multiplexed Signals

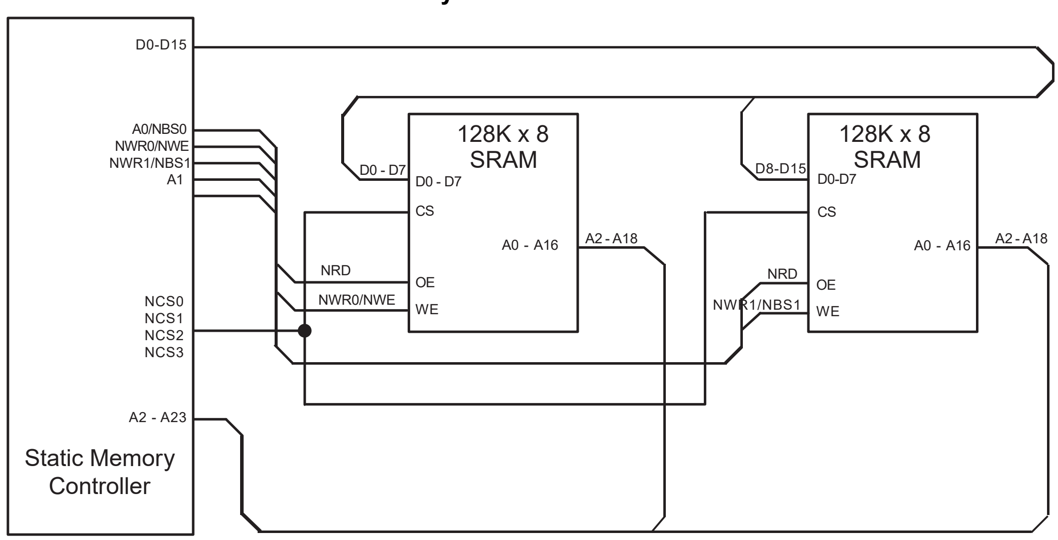
Table 16-2. SMC Multiplexed Signals

Multiplexed Signals		Related Function
NWR0	NWE	Byte-write or Byte-select access, see Byte Write Access and Byte Select Access
A0	NBS0	8-bit or 16-bit data bus, see Data Bus Width
A22	NANDCLE	NAND Flash Command Latch Enable
A21	NANDALE	NAND Flash Address Latch Enable
NWR1	NBS1	Byte-write or Byte-select access, see Byte Write Access and Byte Select Access
A1	–	8-/16-bit data bus, see Data Bus Width Byte-write or Byte-select access, see Byte Write Access and Byte Select Access

16.6 Application Example

16.6.1 Hardware Interface

Figure 16-2. SMC Connections to Static Memory Devices



16.7 Product Dependencies

16.7.1 I/O Lines

The pins used for interfacing the Static Memory Controller are multiplexed with the PIO lines. The programmer must first program the PIO controller to assign the Static Memory Controller pins to their peripheral function. If I/O lines of the SMC are not used by the application, they can be used for other purposes by the PIO controller.

16.7.2 Power Management

The SMC is clocked through the Power Management Controller (PMC), thus the programmer must first configure the PMC to enable the SMC clock.

16.7.3 Interrupt Sources

The SMC has an interrupt line connected to the interrupt controller. Handling the SMC interrupt requires programming the interrupt controller before configuring the SMC.

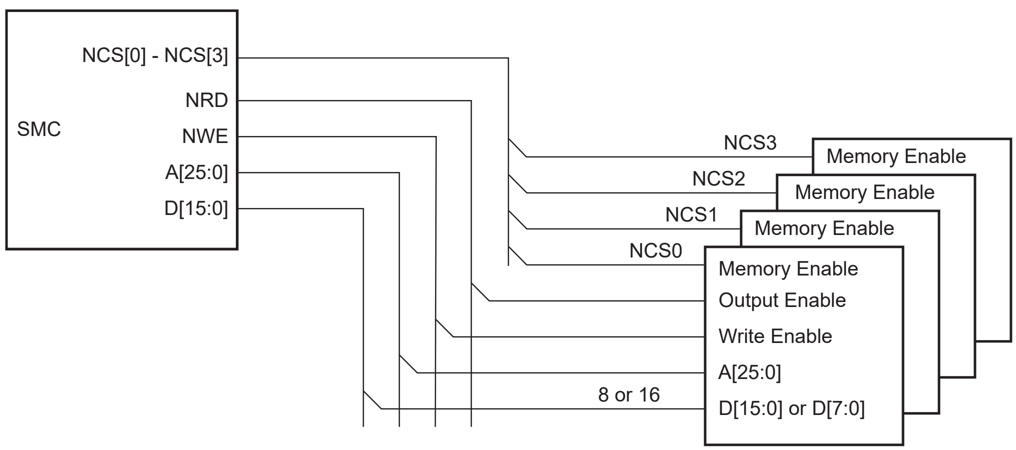
16.8 External Memory Mapping

The SMC provides up to 26 address lines, A[25:0]. This allows each chip select line to address up to 128 Mbytes of memory.

If the physical memory device connected on one chip select is smaller than 128 Mbytes, it wraps around and appears to be repeated within this space. The SMC correctly handles any valid access to the memory device within the page. See the figure below.

A[25:0] is only significant for 8-bit memory; A[25:1] is used for 16-bit memory.

Figure 16-3. Memory Connections for External Devices



16.9 Connection to External Devices

16.9.1 Data Bus Width

A data bus width of 8 or 16 bits can be selected for each chip select. This option is controlled by the bit DBW in the Mode register (HSMC_MODE) for the corresponding chip select.

The figure Memory Connection for an 8-bit Data Bus shows how to connect a 512 KB x 8-bit memory on NCS2. The figure Memory Connection for a 16-bit Data Bus shows how to connect a 512 KB x 16-bit memory on NCS2.

Figure 16-4. Memory Connection for an 8-bit Data Bus

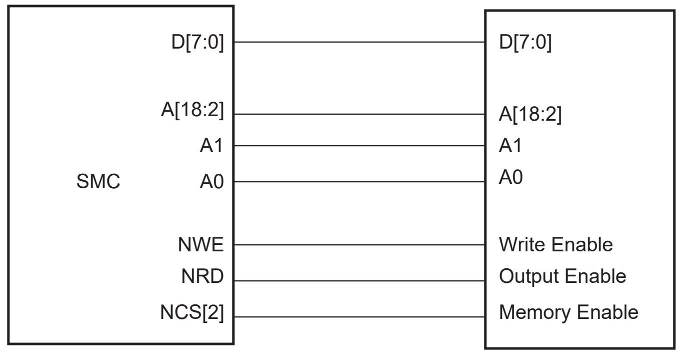


Figure 16-5. Memory Connection for a 16-bit Data Bus

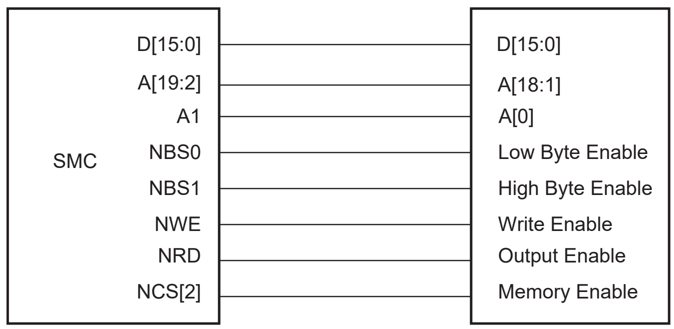


16.9.2 Byte Write or Byte Select Access

Each chip select with a 16-bit data bus can operate with one of two different types of write access: Byte Write or Byte Select. This is controlled by HSMC_MODE.BAT for the corresponding chip select.

16.9.2.1 Byte Write Access

Byte Write Access is used to connect 2 x 8-bit devices as a 16-bit memory, and supports one write signal per byte of the data bus and a single read signal.

Note that the SMC does not allow boot in Byte Write Access mode.

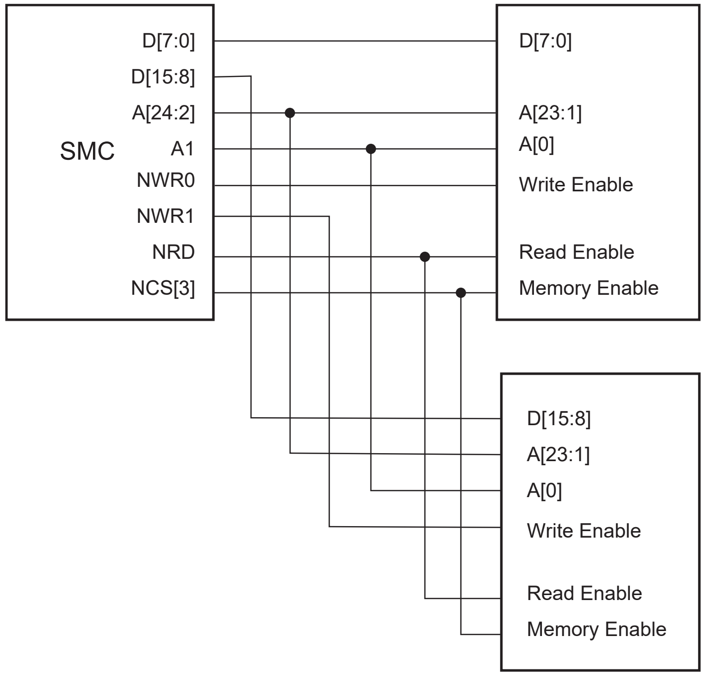
For 16-bit devices, the SMC provides NWR0 and NWR1 write signals for respectively Byte0 (lower byte) and Byte1 (upper byte) of a 16-bit bus. One single read signal (NRD) is provided.

16.9.2.2 Byte Select Access

Byte Select Access is used to connect one 16-bit device. In this mode, read/write operations can be enabled/disabled at Byte level. One Byte-select line per byte of the data bus is provided. One NRD and one NWE signal control read and write.

For 16-bit devices, the SMC provides NBS0 and NBS1 selection signals for respectively Byte0 (lower byte) and Byte1 (upper byte) of a 16-bit bus.

Figure 16-6. Connection of 2 x 8-bit Devices on a 16-bit Bus: Byte Write Option



16.9.2.3 Signal Multiplexing

Depending on the Byte Access Type (BAT), only the write signals or the byte select signals are used. To save IOs at the external bus interface, control signals at the SMC interface are multiplexed. The table below shows signal multiplexing depending on the data bus width and the Byte Access Type.

For 16-bit devices, bit A0 of the address is unused. When the Byte Select option is selected, NWR1 is unused. When the Byte Write option is selected, NBS0 is unused.

Table 16-3. SMC Multiplexed Signal Translation

Device Type	Signal Name		
	16-bit Bus		8-bit Bus
	1 x 16-bit	2 x 8-bit	1 x 8-bit
Byte Access Type (BAT)	Byte Select	Byte Write	–
NBS0_A0	NBS0	–	A0
NWE_NWR0	NWE	NWR0	NWE
NBS1_NWR1	NBS1	NWR1	–
A1	A1	A1	A1

16.10 Standard Read and Write Protocols

In the following sections, the Byte Access Type is not considered. Byte select lines (NBS0 to NBS1) always have the same timing as the A address bus. NWE represents either the NWE signal in byte select access type or one of the byte write lines (NWR0 to NWR1) in byte write access type. NWR0 to NWR1 have the same timings and protocol as NWE. In the same way, NCS represents one of the NCS[0..3] chip select lines.

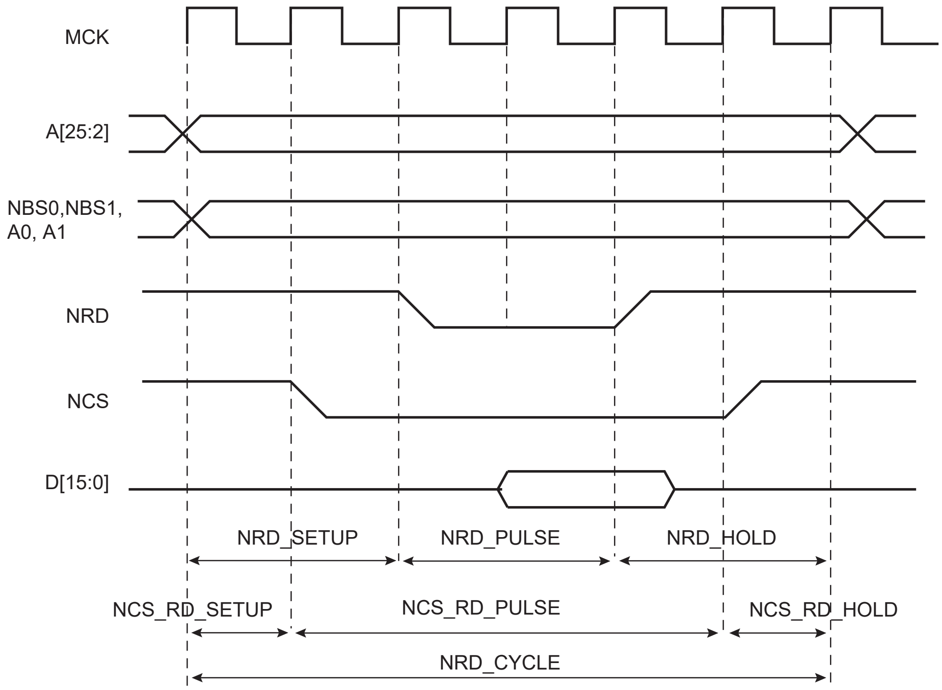
16.10.1 Read Waveforms

The read cycle is shown in the figure below.

The read cycle starts with the address setting on the memory address bus, i.e.:

- {A[25:2], A1, A0} for 8-bit devices
- {A[25:2], A1} for 16-bit devices

Figure 16-7. Standard Read Cycle



16.10.1.1 NRD Waveform

The NRD signal is characterized by a setup time, a pulse length and a hold time:

1. NRD_SETUP: the NRD setup time is defined as the setup of the address before the NRD falling edge.
2. NRD_PULSE: the NRD pulse length is the time between the NRD falling edge and the NRD rising edge.
3. NRD_HOLD: the NRD hold time is defined as the hold time of the address after the NRD rising edge.

16.10.1.2 NCS Waveform

Similar to the NRD signal, the NCS signal can be divided into a setup time, a pulse length and a hold time:

- NCS_RD_SETUP: the NCS setup time is defined as the setup time of the address before the NCS falling edge.
- NCS_RD_PULSE: the NCS pulse length is the time between the NCS falling edge and the NCS rising edge.
- NCS_RD_HOLD: the NCS hold time is defined as the hold time of the address after the NCS rising edge.

16.10.1.3 Read Cycle

The NRD_CYCLE time is defined as the total duration of the read cycle, that is, from the time when the address is set on the address bus to the point when the address may change. The total read cycle time is defined as:

- NRD_CYCLE = NRD_SETUP + NRD_PULSE + NRD_HOLD

as well as

- NRD_CYCLE = NCS_RD_SETUP + NCS_RD_PULSE + NCS_RD_HOLD

All NRD and NCS timings are defined separately for each chip select as an integer number of main system bus clock cycles. The NRD_CYCLE field is common to both the NRD and NCS signals, thus the timing period is of the same duration.

NRD_CYCLE, NRD_SETUP and NRD_PULSE implicitly define the NRD_HOLD value as:

- NRD_HOLD = NRD_CYCLE - NRD SETUP - NRD PULSE

NRD_CYCLE, NCS_RD_SETUP and NCS_RD_PULSE implicitly define the NCS_RD_HOLD value as:

- NCS_RD_HOLD = NRD_CYCLE - NCS_RD_SETUP - NCS_RD_PULSE

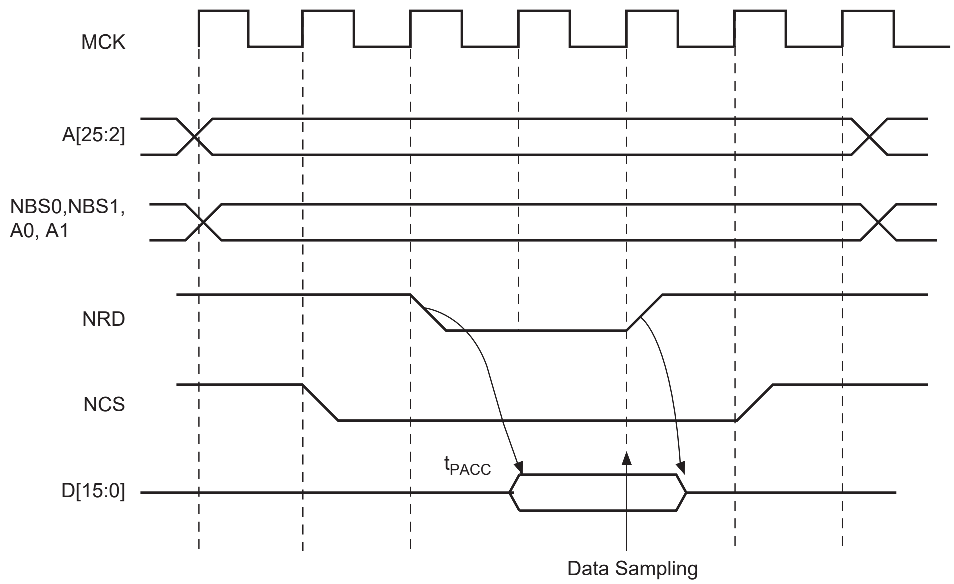
16.10.2 Read Mode

As NCS and NRD waveforms are defined independently of one another, the SMC needs to know when the read data is available on the data bus. The SMC does not compare NCS and NRD timings to know which signal rises first.
The READ_MODE parameter in the HSMC_MODE register of the corresponding chip select indicates which signal of NRD and NCS controls the read operation.

16.10.2.1 Read is Controlled by NRD (READ_MODE = 1)

The figure below shows the waveforms of a read operation of a typical asynchronous RAM. The read data is available t_{PACC} after the falling edge of NRD, and turns to ‘Z’ after the rising edge of NRD. In this case, the READ_MODE must be set to 1 (read is controlled by NRD), to indicate that data is available with the rising edge of NRD. The SMC samples the read data internally on the rising edge of the main system bus clock that generates the rising edge of NRD, whatever the programmed waveform of NCS.

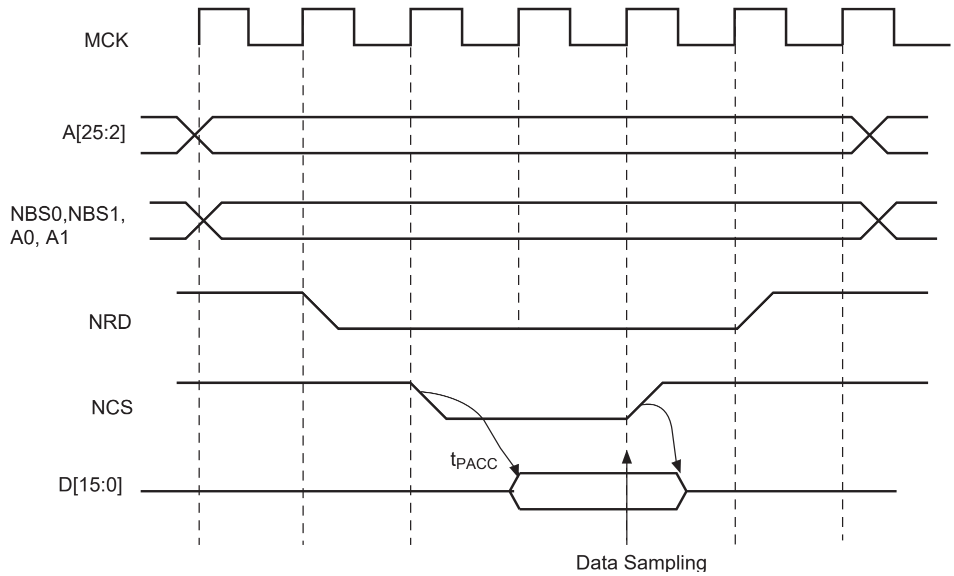
Figure 16-8. READ_MODE = 1: Data is Sampled by SMC before the Rising Edge of NRD



16.10.2.2 Read is Controlled by NCS (READ_MODE = 0)

The figure below shows the typical read cycle. The read data is valid t_{PACC} after the falling edge of the NCS signal and remains valid until the rising edge of NCS. Data must be sampled when NCS is raised. In that case, the READ_MODE must be configured to 0 (read is controlled by NCS): the SMC internally samples the data on the rising edge of the main system bus clock that generates the rising edge of NCS, whatever the programmed waveform of NRD.

Figure 16-9. READ_MODE = 0: Data is Sampled by SMC before the Rising Edge of NCS



16.10.3 Write Waveforms

The write protocol, similar to the read protocol, is depicted in the following figure. The write cycle starts with the address setting on the memory address bus.

16.10.3.1 NWE Waveforms

The NWE signal is characterized by a setup time, a pulse length and a hold time:

- NWE_SETUP: the NWE setup time is defined as the setup of the address and data before the NWE falling edge.
- NWE_PULSE: the NWE pulse length is the time between the NWE falling edge and the NWE rising edge.
- NWE_HOLD: the NWE hold time is defined as the hold time of the address and data after the NWE rising edge.

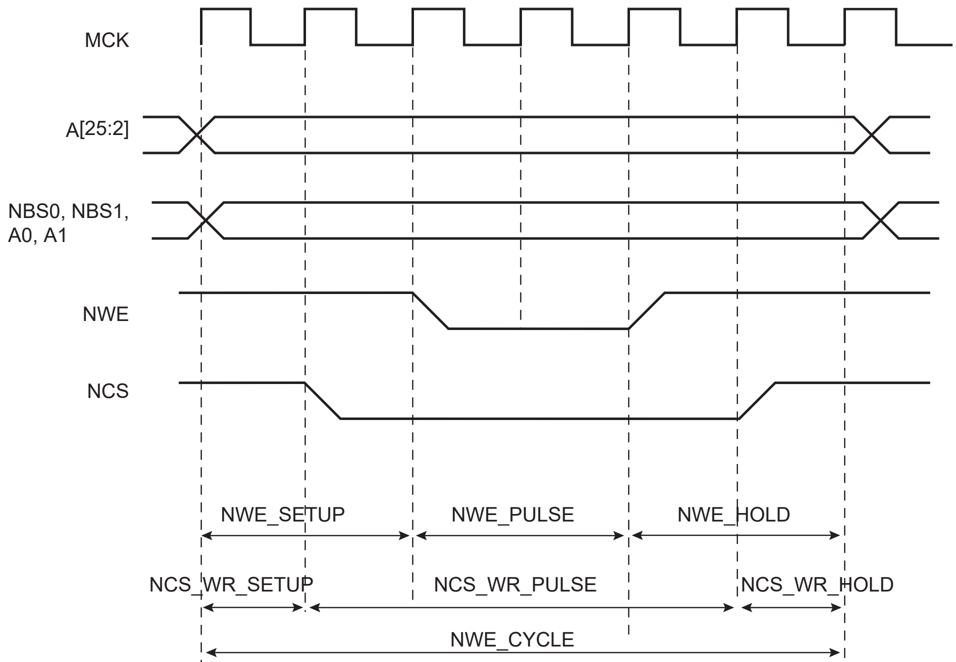
The NWE waveforms apply to all byte-write lines in Byte Write Access mode: NWR0 to NWR3.

16.10.3.2 NCS Waveforms

The NCS signal waveforms in write operations are not the same as those applied in read operations, but are defined separately:

- NCS_WR_SETUP: the NCS setup time is defined as the setup time of the address before the NCS falling edge.
- NCS_WR_PULSE: the NCS pulse length is the time between the NCS falling edge and the NCS rising edge.
- NCS_WR_HOLD: the NCS hold time is defined as the hold time of the address after the NCS rising edge.

Figure 16-10. Write Cycle



16.10.3.3 Write Cycle

The write cycle time is defined as the total duration of the write cycle, that is, from the time when the address is set on the address bus to the point when the address may change. The total write cycle time is equal to:

- NWE_CYCLE = NWE_SETUP + NWE_PULSE + NWE_HOLD

as well as

- NWE_CYCLE = NCS_WR_SETUP + NCS_WR_PULSE + NCS_WR_HOLD

All NWE and NCS (write) timings are defined separately for each chip select as an integer number of main system bus clock cycles. The NWE_CYCLE field is common to both the NWE and NCS signals, thus the timing period is of the same duration.

NWE_CYCLE, NWE_SETUP and NWE_PULSE implicitly define the NWE_HOLD value as:

- NWE_HOLD = NWE_CYCLE - NWE_SETUP - NWE_PULSE

NWE_CYCLE, NCS_WR_SETUP and NCS_WR_PULSE implicitly define the NCS_WR_HOLD value as:

- NCS_WR_HOLD = NWE_CYCLE - NCS_WR_SETUP - NCS_WR_PULSE

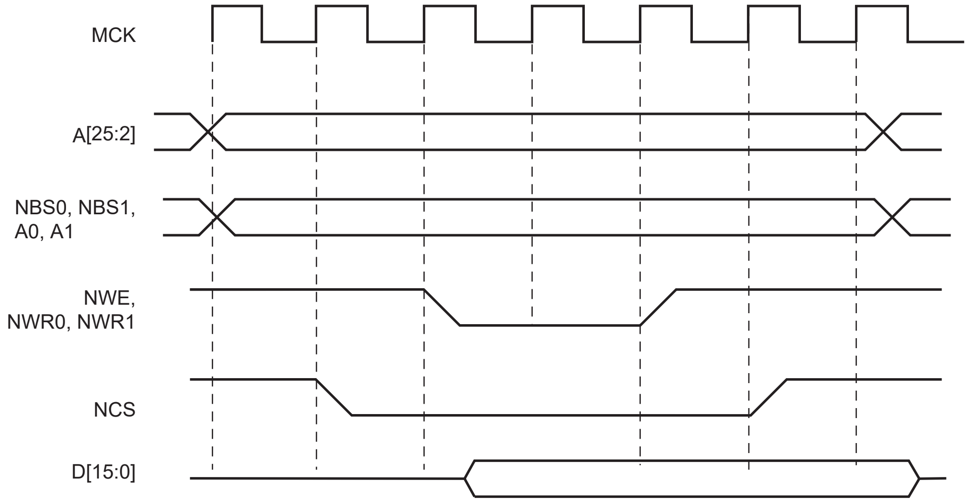
16.10.4 Write Mode

The WRITE_MODE parameter in the HSMC_MODE register of the corresponding chip select indicates which signal controls the write operation.

16.10.4.1 Write is Controlled by NWE (WRITE_MODE = 1)

The figure below shows the waveforms of a write operation with WRITE_MODE set to 1. The data is put on the bus during the pulse and hold steps of the NWE signal. The internal data buffers are switched to Output mode after the NWE_SETUP time, and until the end of the write cycle, regardless of the programmed waveform on NCS.

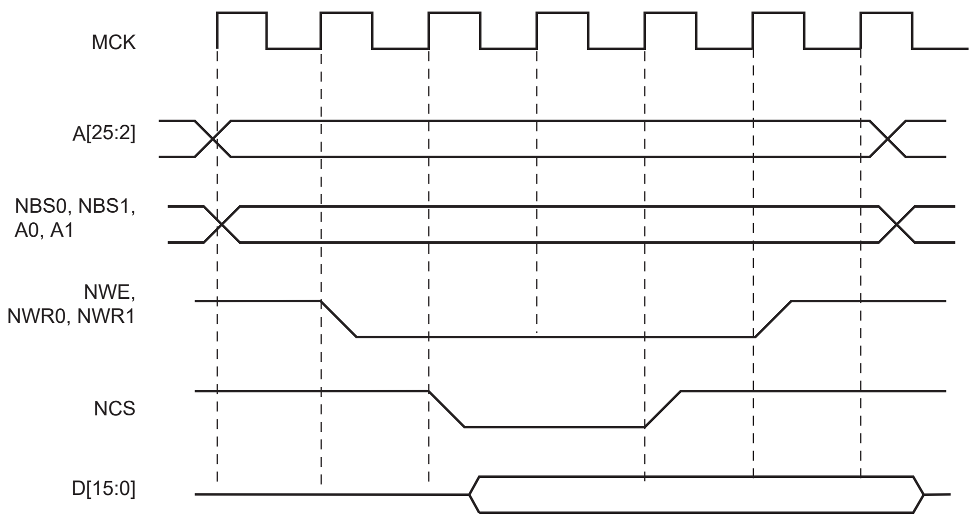
Figure 16-11. WRITE_MODE = 1. The write operation is controlled by NWE



16.10.4.2 Write is Controlled by NCS (WRITE_MODE = 0)

The figure below shows the waveforms of a write operation with WRITE_MODE configured to 0. The data is put on the bus during the pulse and hold steps of the NCS signal. The internal data buffers are switched to Output mode after the NCS_WR_SETUP time, and until the end of the write cycle, regardless of the programmed waveform on NWE.

Figure 16-12. WRITE_MODE = 0. The write operation is controlled by NCS

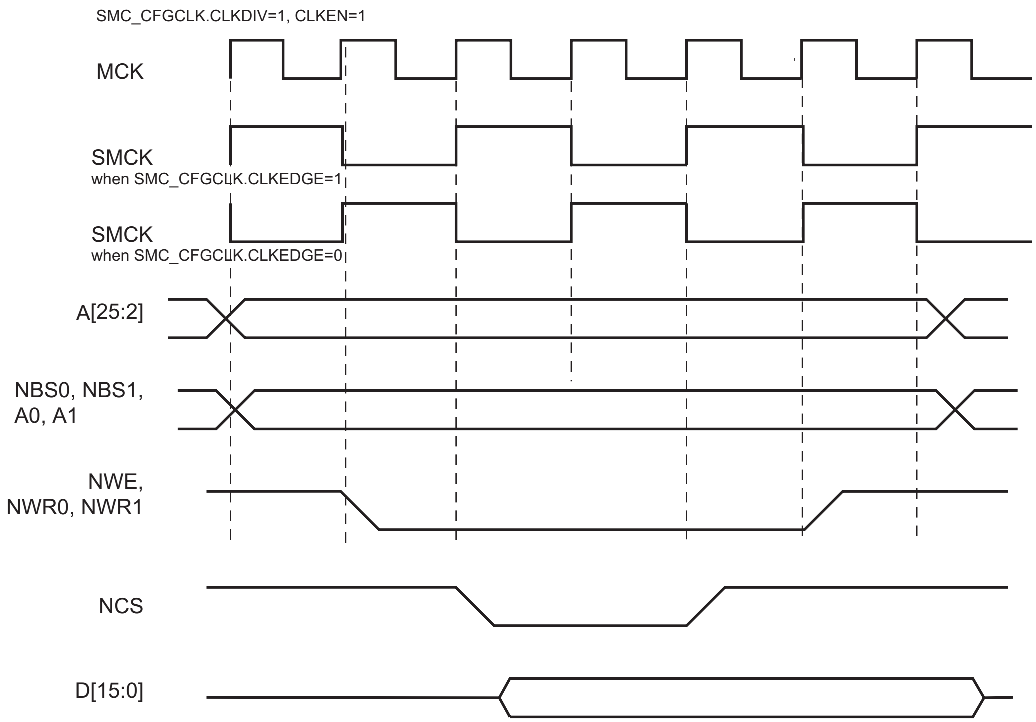


16.10.5 External Bus Clock

The SMC provides an external bus clock synchronous to the address, data and control signals. When SMC_CFGCLK.CLKEN=1, the frequency of the output clock is periph_clock/ (CLKDIV+1).

The start of the access to the external memory device can be aligned on the rising or falling edge of the output clock by configuring the SMC_CFGCLK.CLKEDGE.

Figure 16-13. SMC Clock Output Waveform



16.10.6 Coding Timing Parameters

All timing parameters are defined for one chip select and are grouped together in one register according to their type:

- The HSMC_SETUP register groups the definition of all setup parameters:
  NRD_SETUP, NCS_RD_SETUP, NWE_SETUP, NCS_WR_SETUP
- The HSMC_PULSE register groups the definition of all pulse parameters:
  NRD_PULSE, NCS_RD_PULSE, NWE_PULSE, NCS_WR_PULSE
- The HSMC_CYCLE register groups the definition of all cycle parameters:
  NRD_CYCLE, NWE_CYCLE

The table below shows how the timing parameters are coded and their permitted range.

Table 16-4. Coding and Range of Timing Parameters

Coded Value	Number of Bits	Effective Value	Permitted Range	
			Coded Value	Effective Value
setup [5:0]	6	128 x setup[5] + setup[4:0]	0 ≤ setup ≤ 31	0..31
			32 ≤ setup ≤ 63	128..(128 + 31)
pulse [6:0]	7	256 x pulse[6] + pulse[5:0]	0 ≤ pulse ≤ 63	0..63
			64 ≤ pulse ≤ 127	256..(256 + 63)
cycle[8:0]	9	256 x cycle[8:7] + cycle[6:0]	0 ≤ cycle ≤ 127	0..127
			128 ≤ cycle ≤ 255	256..(256 + 127)
			256 ≤ cycle ≤ 383	512..(512 + 127)
			384 ≤ cycle ≤ 511	768..(768 + 127)

16.10.7 Reset Values of Timing Parameters

The table below gives the default value of timing parameters at reset.

Table 16-5. Reset Values of Timing Parameters

Register	Reset Value	Description
HSMC_SETUP	0x01010101	All setup timings are set to 1.
HSMC_PULSE	0x01010101	All pulse timings are set to 1.
HSMC_CYCLE	0x00030003	The read and write operations last three main system bus clock cycles and provide one hold cycle.
WRITE_MODE	1	Write is controlled with NEW.
READ_MODE	1	Read is controlled with NRD.

16.10.8 Usage Restriction

The SMC does not check the validity of the user-programmed parameters. If the sum of SETUP and PULSE parameters is larger than the corresponding CYCLE parameter, this leads to an unpredictable behavior of the SMC.

16.10.8.1 For Read Operations

Null but positive setup and hold of address and NRD and/or NCS cannot be ensured at the memory interface because of the propagation delay of these signals through external logic and pads. When positive setup and hold values must be verified, then it is strictly recommended to program non-null values so as to cover possible skews between address, NCS and NRD signals.

16.10.8.2 For Write Operations

If a null hold value is programmed on NWE, the SMC can ensure a positive hold of address, byte select lines, and NCS signal after the rising edge of NWE. This is true for WRITE_MODE = 1 only. See Early Read Wait State.

16.10.8.3 For Read and Write Operations

A null value for pulse parameters is forbidden and may lead to an unpredictable behavior.

In read and write cycles, the setup and hold time parameters are defined in reference to the address bus. For external devices that require setup and hold time between NCS and NRD signals (read), or between NCS and NWE signals (write), these setup and hold times must be converted into setup and hold times in reference to the address bus.

16.11 Scrambling/Unscrambling Function

The external data bus D[15:0] can be scrambled in order to make recovery of intellectual property data located in off-chip memories more difficult by analyzing data at the package pin level of either the microcontroller or the memory device.

The scrambling and unscrambling are performed on-the-fly without additional wait states.

The scrambling method depends on two user-configurable key registers, HSMC_KEY1 and HSMC_KEY2. These key registers are only accessible in Write mode.

The key must be securely stored in a reliable nonvolatile memory in order to recover data from the off-chip memory. Any data scrambled with a given key cannot be recovered if the key is lost.

The scrambling/unscrambling function is enabled or disabled by configuring specific bits in the HSMC_OCMS and the HSMC_TIMINGSx registers. The bit configuration values to enable memory scrambling are summarized in the table below.

Table 16-6. Scrambling Function Bit Encoding

Memories	Bit Values		
	HSMC_OCMS.SMSE	HSMC_OCMS.SRSE	HSMC_TIMINGSx.OCMS
Off-chip Memories	1	0	1
NAND Flash with NFC	0	1	0

When the NAND Flash memory content is scrambled, the on-chip NFC SRAM page buffer associated for the transfer is also scrambled.

16.12 Automatic Wait States

Under certain circumstances, the SMC automatically inserts idle cycles between accesses to avoid bus contention or operation conflict.

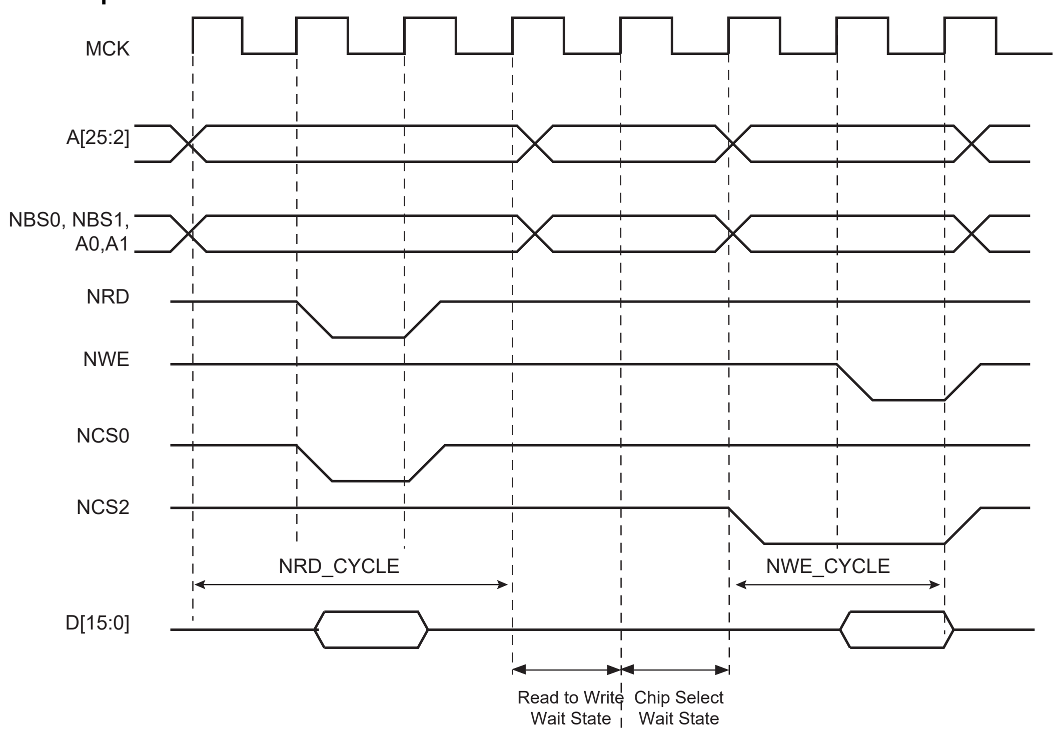
16.12.1 Chip Select Wait States

The SMC always inserts an idle cycle between two transfers on separate chip selects. This idle cycle ensures that there is no bus contention between the deactivation of one device and the activation of the next one.

During chip select wait state, all control lines are turned inactive: NBS0 to NBS1, NWR0 to NWR1, NCS[0..3], and NRD lines. They are all set to 1.

The figure below illustrates a chip select wait state between access on Chip Select 0 and Chip Select 2.

Figure 16-14. Chip Select Wait State between a Read Access on NCS0 and a Write Access on NCS2



16.12.2 Early Read Wait State

In some cases, the SMC inserts a wait state cycle between a write access and a read access to allow time for the write cycle to end before the subsequent read cycle begins. This wait state is not generated in addition to a chip select wait state. The early read cycle thus only occurs between a write and read access to the same memory device (same chip select).

An early read wait state is automatically inserted if at least one of the following conditions is valid:

- if the write controlling signal has no hold time and the read controlling signal has no setup time (see figure Early Read Wait State: Write with No Hold Followed by Read with No Setup).
- in NCS Write Controlled mode (WRITE_MODE = 0), if there is no hold timing on the NCS signal and the NCS_RD_SETUP parameter is configured to 0, regardless of the Read mode (see figure Early Read Wait State: NCS Controlled Write with No Hold Followed by a Read with No NCS Setup). The write operation must end with an NCS rising edge. Without an Early Read Wait State, the write operation could not complete properly.
- in NWE Controlled mode (WRITE_MODE = 1) and if there is no hold timing (NWE_HOLD = 0), the feedback of the write control signal is used to control address, data, chip select and byte select lines. If the external write control signal is not inactivated as expected due to load capacitances, an Early Read Wait State is inserted and address, data and control signals are maintained one more cycle. See figure Early Read Wait State: NWE-controlled Write with No Hold Followed by a Read with One Setup Cycle.

Figure 16-15. Early Read Wait State: Write with No Hold Followed by Read with No Setup

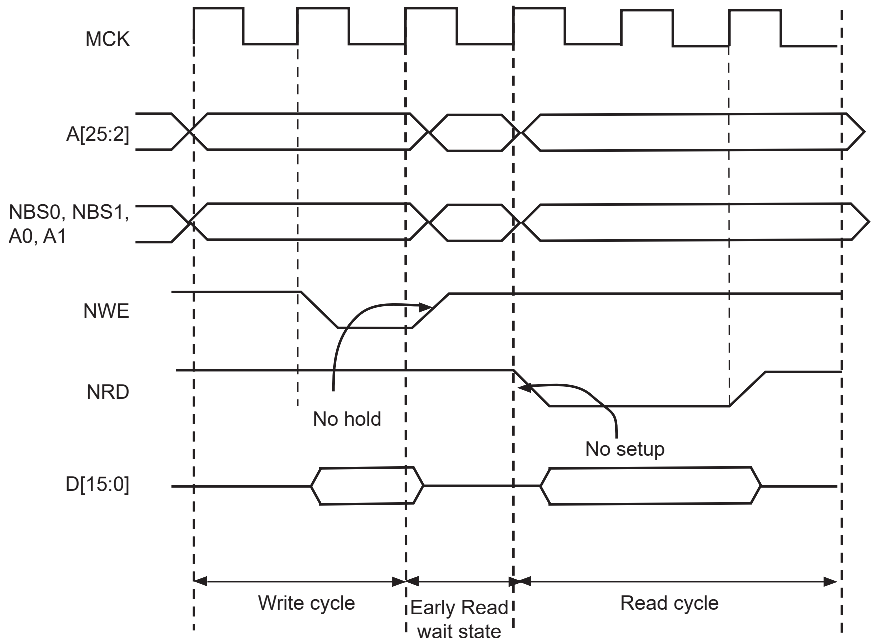


Figure 16-16. Early Read Wait State: NCS Controlled Write with No Hold Followed by a Read with No NCS Setup

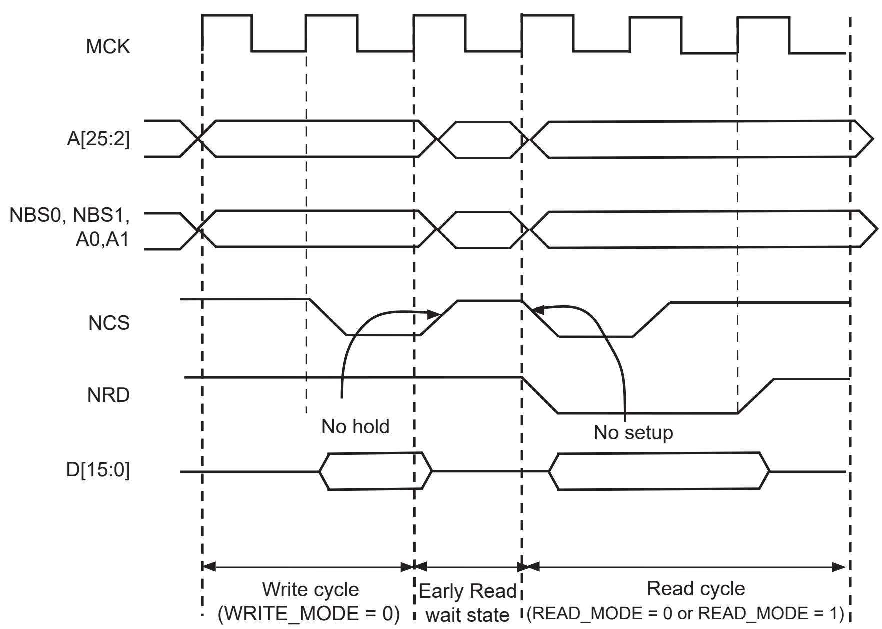

Figure 16-17. Early Read Wait State: NWE-controlled Write with No Hold Followed by a Read with One Setup Cycle

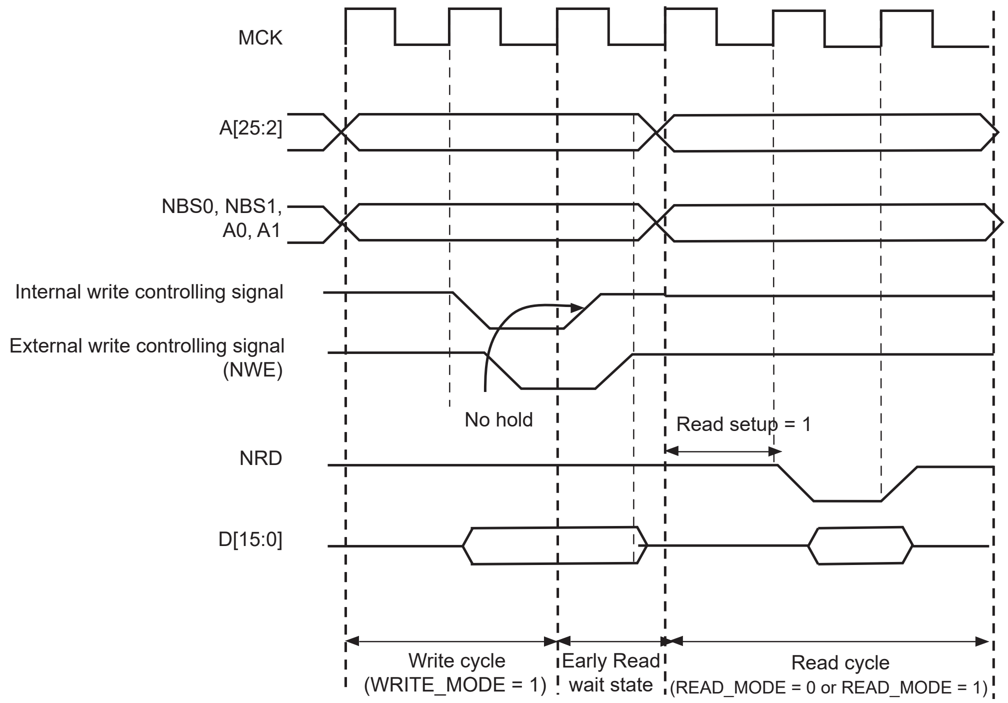

16.12.3 Reload User Configuration Wait State

The user may change any of the configuration parameters by writing the SMC user interface.

When detecting that a new user configuration has been written in the user interface, the SMC inserts a wait state before starting the next access. The so called “Reload User Configuration Wait State” is used by the SMC to load the new set of parameters to apply to next accesses.

The Reload Configuration Wait State is not applied in addition to the Chip Select Wait State. If accesses before and after reprogramming the user interface are made to different devices (Chip Selects), then one single Chip Select Wait State is applied.

On the other hand, if accesses before and after writing the user interface are made to the same device, a Reload Configuration Wait State is inserted, even if the change does not concern the current Chip Select.

16.12.3.1 User Procedure

To insert a Reload Configuration Wait State, the SMC detects a write access to any HSMC_MODE register of the user interface. If only the timing registers are modified (HSMC_SETUP, HSMC_PULSE, HSMC_CYCLE registers) in the user interface, the user must validate the modification by writing the HSMC_MODE register, even if no change was made on the mode parameters.

16.12.3.2 Slow Clock Mode Transition

A Reload Configuration Wait state is also inserted when Slow Clock mode is entered or exited, after the end of the current transfer (see Slow Clock Mode).

16.12.4 Read to Write Wait State

Due to an internal mechanism, a wait cycle is always inserted between consecutive read and write SMC accesses.

This wait cycle is referred to as a read to write wait state in this document.

This wait cycle is applied in addition to chip select and reload user configuration wait states when they are to be inserted. See figure Chip Select Wait State between a Read Access on NCS0 and a Write Access on NCS2.

16.13 External Wait

Any access can be extended by an external device using the NWAIT input signal of the SMC. The EXNW_MODE field of the HSMC_MODE register on the corresponding chip select must be set to either ‘10’ (Frozen mode) or ‘11’ (Ready mode). When the EXNW_MODE is set to ‘00’ (disabled), the NWAIT signal is simply ignored on the corresponding chip select. The NWAIT signal delays the read or write operation related to the read or write controlling signal, depending on the Read and Write modes of the corresponding chip select.

16.13.1 Restriction

When one of the EXNW_MODE is enabled, at least one hold cycle must be programmed for the read/write controlling signal. For that reason, the NWAIT signal cannot be used in Slow Clock mode (see Slow Clock Mode).

The NWAIT signal is assumed to be a response of the external device to the read/write request of the SMC. NWAIT is then examined by the SMC in the Pulse state of the read or write controlling signal. The assertion of the NWAIT signal outside the expected period has no impact on the SMC behavior.

16.13.2 Frozen Mode

When the external device asserts the NWAIT signal (active low), and after an internal synchronization of this signal, the SMC state is frozen, i.e., SMC internal counters are frozen, and all control signals remain unchanged. When the resynchronized NWAIT signal is deasserted, the SMC completes the access, resuming the access from the point where it was stopped. See the figure below. This mode must be selected when the external device uses the NWAIT signal to delay the access and to freeze the SMC.

The assertion of the NWAIT signal outside the expected period is ignored as illustrated in the figure Read Access with NWAIT Assertion in Frozen Mode (EXNW_MODE = 10).

Figure 16-18. Write Access with NWAIT Assertion in Frozen Mode (EXNW_MODE = 10)

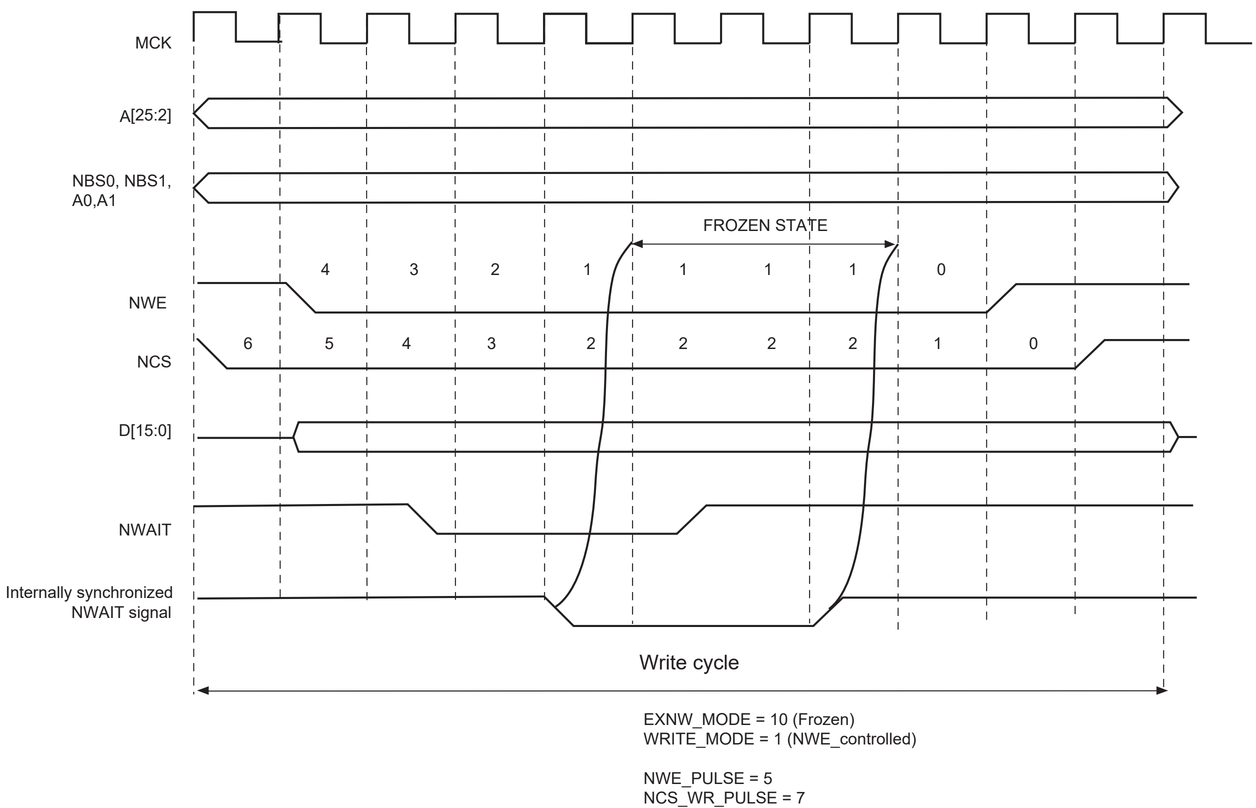

Figure 16-19. Read Access with NWAIT Assertion in Frozen Mode (EXNW_MODE = 10)

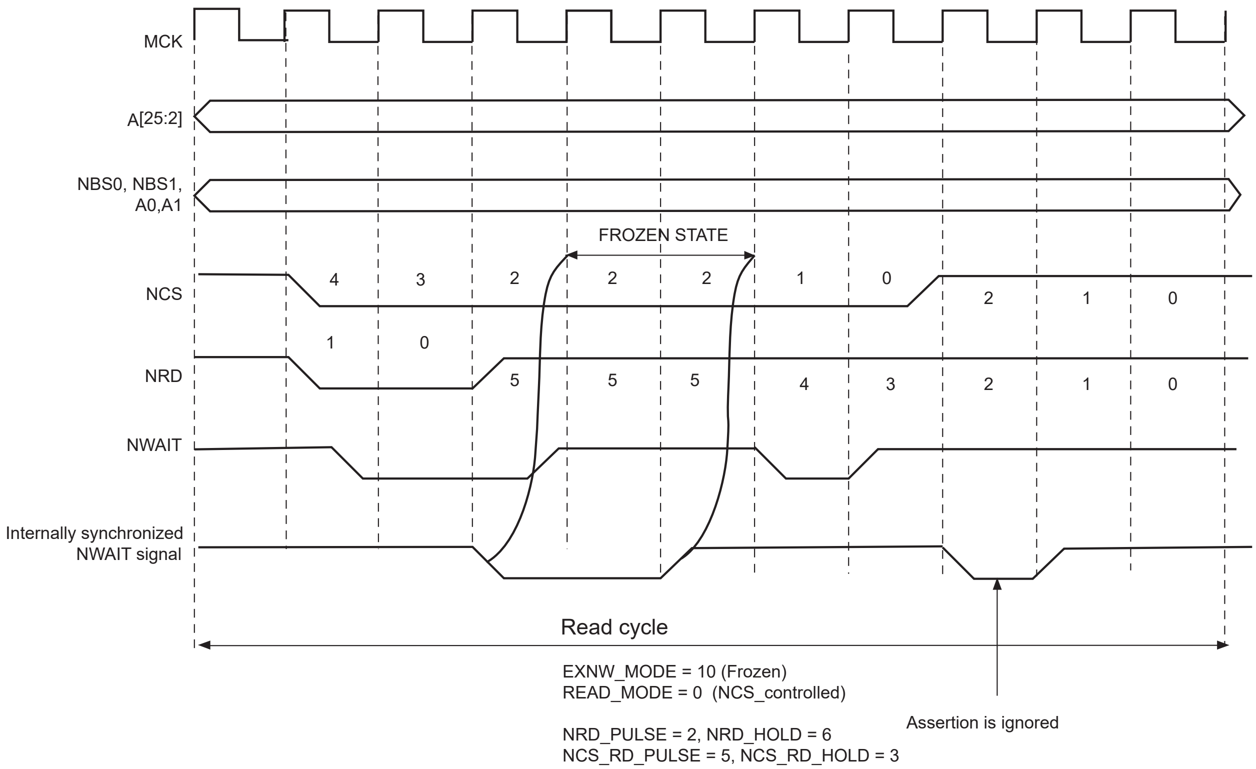

16.13.3 Ready Mode

In Ready mode (EXNW_MODE = 11), the SMC behaves differently. Normally, the SMC begins the access by down counting the setup and pulse counters of the read/write controlling signal. In the last cycle of the pulse phase, the resynchronized NWAIT signal is examined.

If asserted, the SMC suspends the access as shown in the figures below. After deassertion, the access is completed: the hold step of the access is performed.

This mode must be selected when the external device uses deassertion of the NWAIT signal to indicate its ability to complete the read or write operation.

If the NWAIT signal is deasserted before the end of the pulse, or asserted after the end of the pulse of the controlling read/write signal, it has no impact on the access length as shown in the figure NWAIT Assertion in Read Access: Ready Mode (EXNW_MODE = 11).

Figure 16-20. NWAIT Assertion in Write Access: Ready Mode (EXNW_MODE = 11)

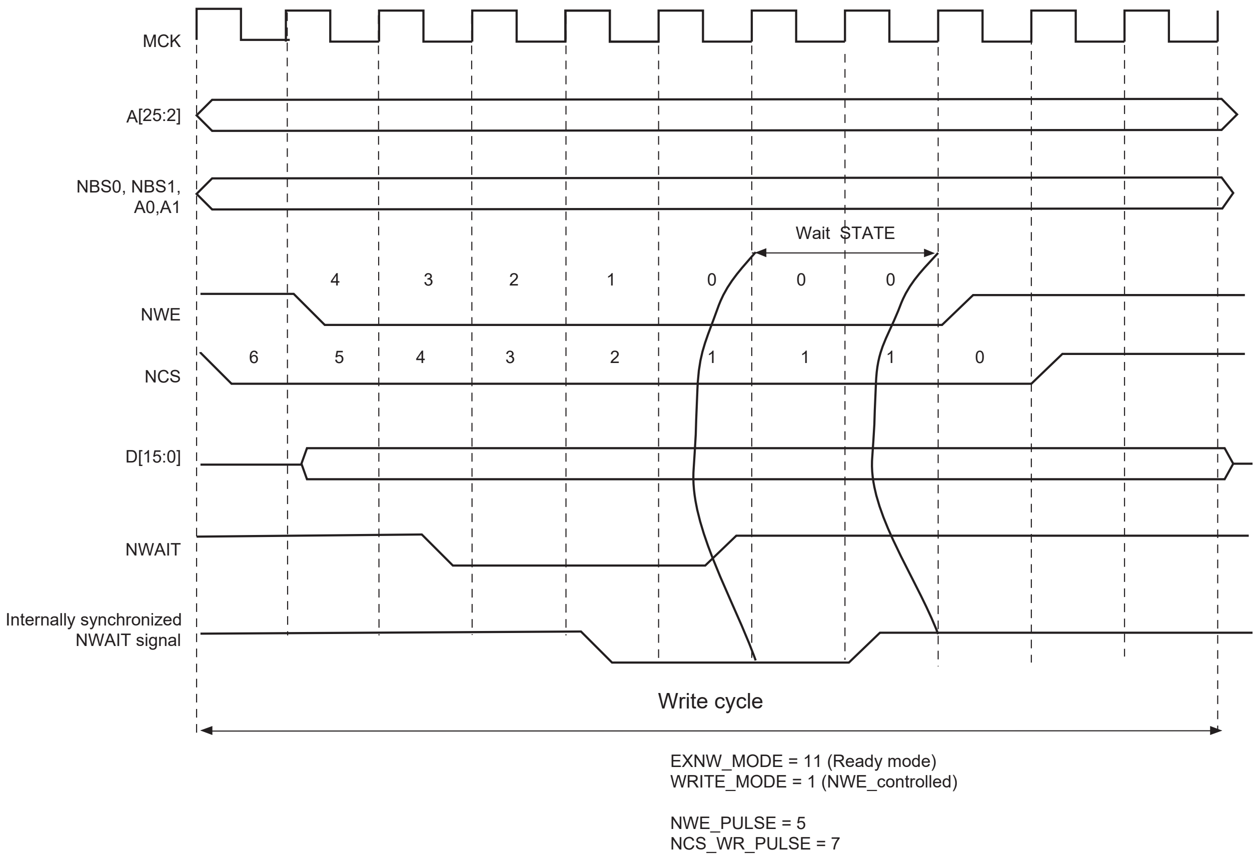

Figure 16-21. NWAIT Assertion in Read Access: Ready Mode (EXNW_MODE = 11)

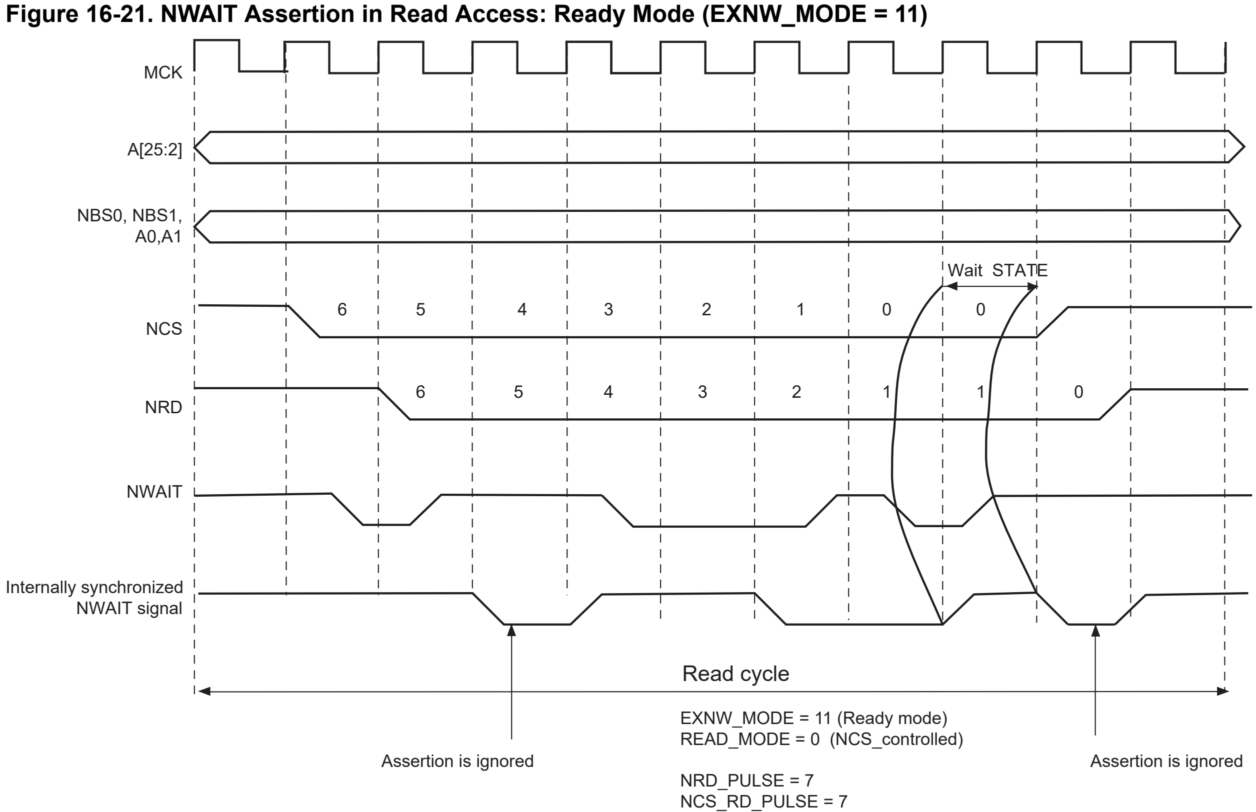


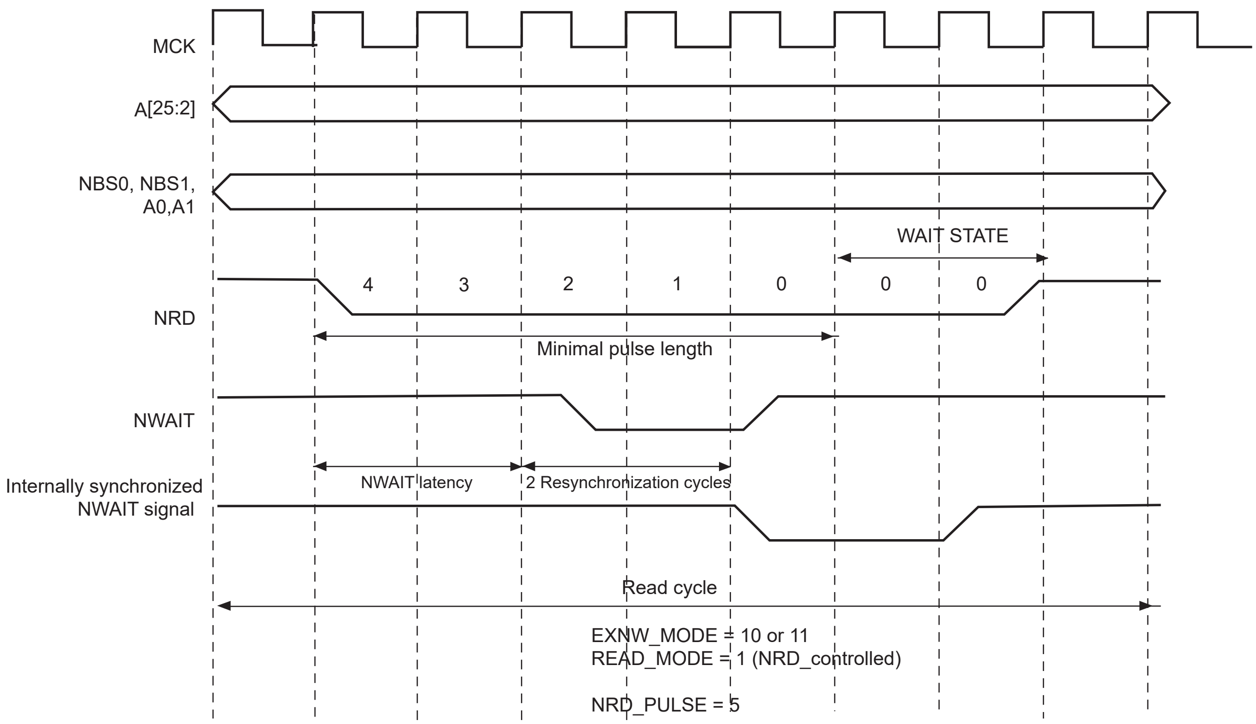
16.13.4 NWAIT Latency and Read/Write Timings

There may be a latency between the assertion of the read/write controlling signal and the assertion of the NWAIT signal by the device. The programmed pulse length of the read/write controlling signal must be at least equal to this latency plus the 2 cycles of resynchronization + 1 cycle. Otherwise, the SMC may enter the hold state of the access without detecting the NWAIT signal assertion. This is true in Frozen mode as well as in Ready mode. This is illustrated in the figure below.

When EXNW_MODE is enabled (ready or frozen), the user must program a pulse length of the read and write controlling signal of at least:

minimal pulse length = NWAIT latency + 2 resynchronization cycles + 1 cycle

Figure 16-22. NWAIT Latency



16.14 Slow Clock Mode

The SMC is able to automatically apply a set of “Slow Clock mode” read/write waveforms when an internal signal driven by the Power Management Controller is asserted because MCK has been turned to a very slow clock rate (typically 32 kHz clock rate). In this mode, the user-programmed waveforms are ignored and the Slow Clock mode waveforms are applied. This mode is provided so as to avoid reprogramming the User Interface with appropriate waveforms at very slow clock rate. When activated, the Slow mode is active on all chip selects.

16.14.1 Slow Clock Mode Waveforms

The figure below illustrates the read and write operations in Slow Clock mode. They are valid on all chip selects. The table below indicates the value of read and write parameters in Slow Clock mode.

Figure 16-23. Write/Read Cycles in Slow Clock Mode

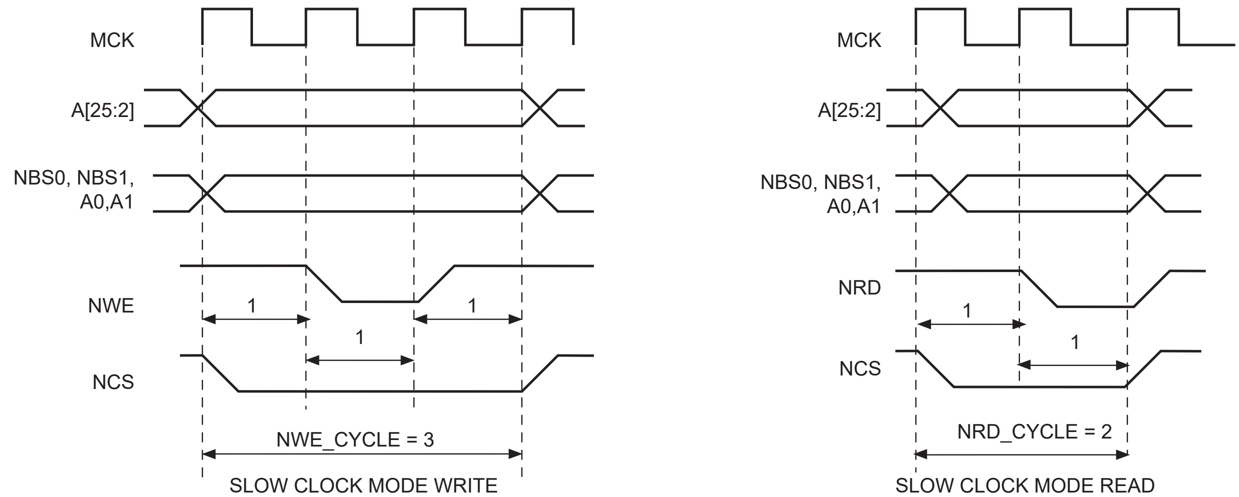


Table 16-7. Read and Write Timing Parameters in Slow Clock Mode

Read Parameters	Duration (cycles)	Write Parameters	Duration (cycles)
NRD_SETUP	1	NWE_SETUP	1
NRD_PULSE	1	NWE_PULSE	1
NCS_RD_SETUP	0	NCS_WR_SETUP	0
NCS_RD_PULSE	2	NCS_WR_PULSE	3
NRD_CYCLE	2	NWE_CYCLE	3

16.14.2 Switching from (to) Slow Clock Mode to (from) Normal Mode

When switching from Slow Clock mode to Normal mode, the current Slow Clock mode transfer is completed at high clock rate, with the set of Slow Clock mode parameters. See the figure Clock Rate Transition occurs while the SMC is performing a Write Operation. The external device may not be fast enough to support such timings.

The figure Recommended Procedure to Switch from Slow Clock Mode to Normal Mode or from Normal Mode to Slow Clock Mode illustrates the recommended procedure to properly switch from one mode to the other.

Figure 16-24. Clock Rate Transition occurs while the SMC is performing a Write Operation

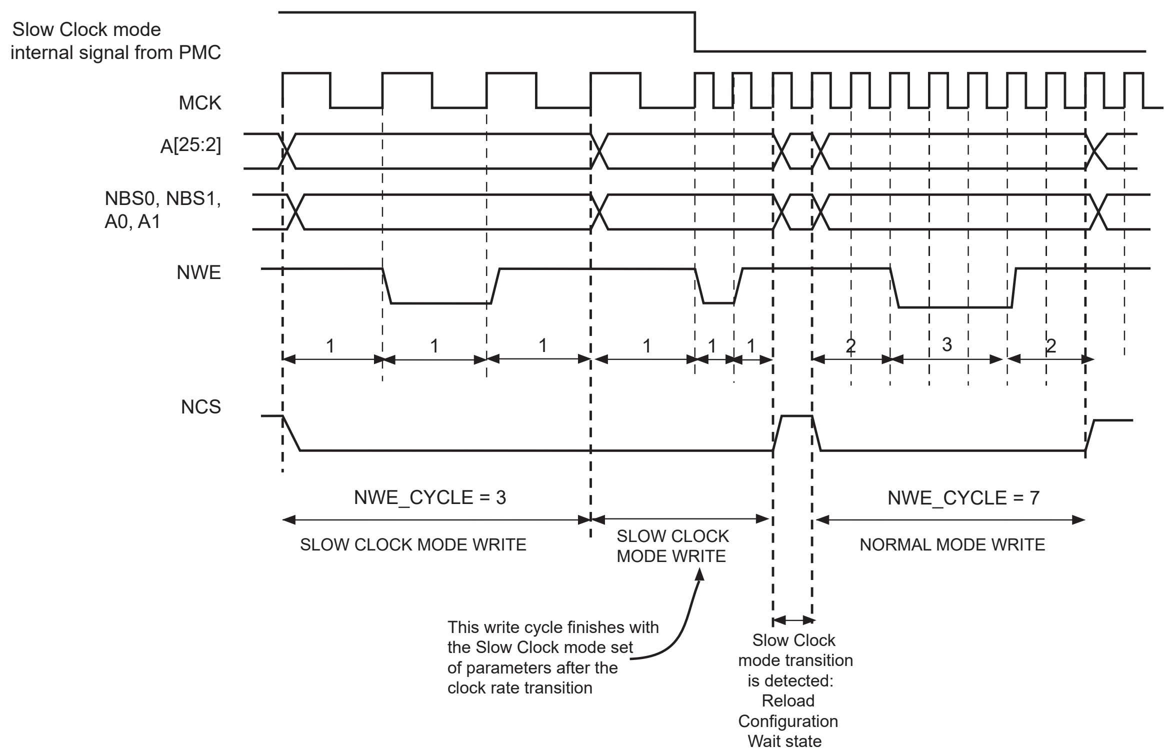

Figure 16-25. Recommended Procedure to Switch from Slow Clock Mode to Normal Mode or from Normal Mode to Slow Clock Mode

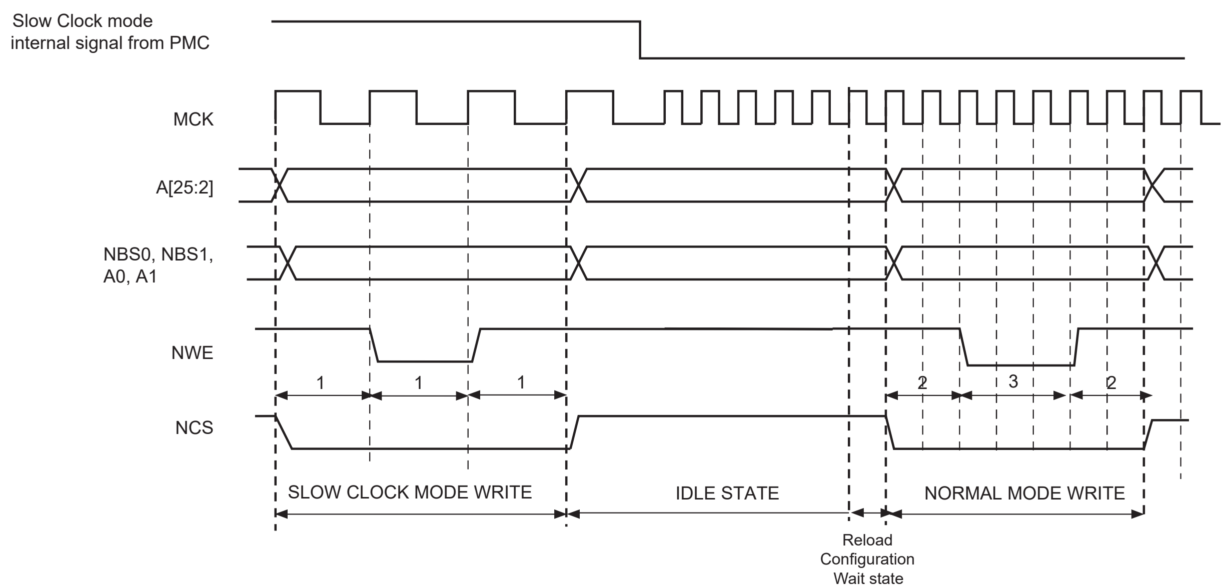


16.15 Register Write Protection

To prevent any single software error that may corrupt SMC behavior, selected registers can be write-protected by setting HSMC_WPMR.WPEN.

If a write access in a write-protected register is detected, then the WPVS flag in the Write Protection Status Register (HSMC_WPSR) is set and the field WPVSRC indicates in which register the write access has been attempted.

The WPVS flag is automatically reset after reading HSMC_WPSR.

The following registers can be write-protected:

- Setup Register
- Pulse Register
- Cycle Register
- Timings Register
- Mode Register

16.16 NFC Operations

16.16.1 NFC Overview

The NFC handles all the command, address and data sequences of the NAND low level protocol. An SRAM is used as an internal read/write buffer when data is transferred from or to the NAND.

16.16.2 NFC Control Registers

NAND Flash Read and NAND Flash Program operations can be performed through the NFC Command registers. In order to minimize CPU intervention and latency, commands are posted in a command buffer. This buffer provides zero wait state latency.

The NFC handles an automatic transfer between the external NAND Flash and the chip via the NFC SRAM. The transfer is done by programming NFC Command registers.

NFC Command registers are very efficient. When writing to these registers:

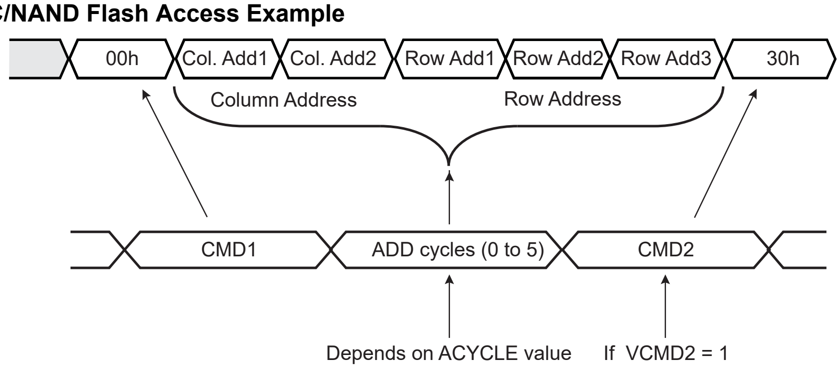
- the address of the register (NFCADDR_CMD) is the command used,
- the data of the register (NFCDATA_ADDT) is the address to be sent to the NAND Flash.

In one single access, the command is sent and immediately executed by the NFC. Two commands can even be programmed within a single access (CMD1, CMD2) depending on the VCMD2 value.

The NFC can send up to five address cycles.

The figure below shows a typical NAND Flash Page Read Command of a NAND Flash Memory and correspondence with the NFC Address Command register.

Figure 16-26. NFC/NAND Flash Access Example



For more details, see NFCADDR_CMD.

Reading the NFC Command register (to any address) gives the status of the NFC. This is especially useful to know if the NFC is busy, for example.

16.16.2.1 Building NFC Address Command Example

The base address is the HOST_ADDR address.

Page read operation example:

```
// Build the Address Command (NFCADDR_CMD)
AddressCommand = (HOST_ADDR |
  NFCWR=0    | // NFC Read Data from NAND Flash
  DATAEN=1   | // NFC Data phase Enable.
  CSID=1     | // Chip Select ID = 1
  ACYCLE= 5  | // Number of address cycle.
  VCMD2=1    | // CMD2 is sent after Address Cycles
  CMD2=0x30  | // CMD2 = 30h
  CMD1=0x0) // CMD1 = Read Command = 00h
 // Set the Address for Cycle 0
 HSMC_ADDR = Col. Add1
 // Write command with the Address Command built above
*AddressCommand = (Col. Add2 | // ADDR_CYCLE1
  Row Add1   | // ADDR_CYCLE2
  Row Add2   | // ADDR_CYCLE3
  Row Add3 )   // ADDR_CYCLE4
```

16.16.2.2 NFC Address Command

Name: NFCADDR_CMD
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
						NFCWR	DATAEN	CSID[2]
Access						R/W	R/W	R/W
Reset								

Bit	23	22	21	20	19	18	17	16
	CSID[1:0]		ACYCLE[2:0]			VCMD2	CMD2[7:6]	
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset								

Bit	15	14	13	12	11	10	9	8
	CMD2[5:0]						CMD1[7:6]	
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset								

Bit	7	6	5	4	3	2	1	0
	CMD1[5:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W		
Reset								

Bit 26 – NFCWR NFC Write Enable

Value	Description
0	NFC reads data from the NAND Flash.
1	NFC writes data into the NAND Flash.

Bit 25 – DATAEN NFC Data Phase Enable
When set to true, the NFC will automatically read or write data after the command.

Bits 24:22 – CSID[2:0] Chip Select Identifier
Chip select used.

Bits 21:19 – ACYCLE[2:0] Number of Address Cycles Required for the Current Command
When ACYCLE field is different from zero, ACYCLE Address cycles are performed after Command Cycle 1. The maximum number of cycles is 5.

Bit 18 – VCMD2 Valid Cycle 2 Command
When set to true, the CMD2 field is issued after the address cycle.

Bits 17:10 – CMD2[7:0] Command Register Value for Cycle 2
When a write access occurs with the VCMD2 field set, the NFC sends this command after CMD1.

Bits 9:2 – CMD1[7:0] Command Register Value for Cycle 1
When a write access occurs, the NFC sends this command.

16.16.2.3 NFC Data Address

Name: NFCDATA_ADDT
Property: Write-only

If five address cycles are used, the first address cycle is ADDR_CYCLE0. See HSMC_ADDR.

Bit	31	30	29	28	27	26	25	24
	ADDR_CYCLE4[7:0]							
Access	W	W	W	W	W	W	W	W
Reset								

Bit	23	22	21	20	19	18	17	16
	ADDR_CYCLE3[7:0]							
Access	W	W	W	W	W	W	W	W
Reset								

Bit	15	14	13	12	11	10	9	8
	ADDR_CYCLE2[7:0]							
Access	W	W	W	W	W	W	W	W
Reset								

Bit	7	6	5	4	3	2	1	0
	ADDR_CYCLE1[7:0]							
Access	W	W	W	W	W	W	W	W
Reset								

Bits 31:24 – ADDR_CYCLE4[7:0] NAND Flash Array Address Cycle 4
When less than five address cycles are used, ADDR_CYCLE4 is the fourth byte written to the NAND Flash.
When five address cycles are used, ADDR_CYCLE4 is the fifth byte written to NAND Flash.

Bits 23:16 – ADDR_CYCLE3[7:0] NAND Flash Array Address Cycle 3
When less than five address cycles are used, ADDR_CYCLE3 is the third byte written to the NAND Flash.
When five address cycles are used, ADDR_CYCLE3 is the fourth byte written to NAND Flash.

Bits 15:8 – ADDR_CYCLE2[7:0] NAND Flash Array Address Cycle 2
When less than five address cycles are used, ADDR_CYCLE2 is the second byte written to the NAND Flash.
When five address cycles are used, ADDR_CYCLE2 is the third byte written to NAND Flash.

Bits 7:0 – ADDR_CYCLE1[7:0] NAND Flash Array Address Cycle 1
When less than five address cycles are used, ADDR_CYCLE1 is the first byte written to the NAND Flash.
When five address cycles are used, ADDR_CYCLE1 is the second byte written to NAND Flash.

16.16.2.4 NFC Data Status

Name: NFCDATA_STATUS
Property: Read-only

Bit	31	30	29	28	27	26	25	24
					NFCBUSY	NFCWR	DATAEN	CSID[2]
Access					R	R	R	R
Reset								

Bit	23	22	21	20	19	18	17	16
	CSID[1:0]		ACYCLE[2:0]			VCMD2	CMD2[7:6]	
Access	R	R	R	R	R	R	R	R
Reset								

Bit	15	14	13	12	11	10	9	8
	CMD2[5:0]						CMD1[7:6]	
Access	R	R	R	R	R	R	R	R
Reset								

Bit	7	6	5	4	3	2	1	0
	CMD1[5:0]							
Access	R	R	R	R	R	R		
Reset								

Bit 27 – NFCBUSY NFC Busy Status Flag
If set to true, it indicates that the NFC is busy.

Bit 26 – NFCWR NFC Write Enable

Value	Description
0	NFC is in Read mode.
1	NFC is in Write mode.

Bit 25 – DATAEN NFC Data Phase Enable
When set to true, the NFC data phase is enabled.

Bits 24:22 – CSID[2:0] Chip Select Identifier
Chip select used.

Bits 21:19 – ACYCLE[2:0] Number of Address Cycles Required for the Current Command
When ACYCLE is different from zero, ACYCLE Address cycles are performed after Command Cycle 1.

Bit 18 – VCMD2 Valid Cycle 2 Command
When set to true, the CMD2 field is issued after the address cycle.

Bits 17:10 – CMD2[7:0] Command Register Value for Cycle 2
When VCMD2 bit is set to true, the Physical Memory Interface drives the IO bus with CMD2 field during the Command Latch cycle 2.

Bits 9:2 – CMD1[7:0] Command Register Value for Cycle 1
When a Read or Write Access occurs, the Physical Memory Interface drives the IO bus with CMD1 field during the Command Latch cycle 1.

16.16.3 NFC Initialization

Prior to any Command and Data Transfer, the SMC User Interface must be configured to meet the device timing requirements.

- Write Enable Configuration

Use NWE_SETUP, NWE_PULSE and NWE_CYCLE to define the write enable waveform according to the external device datasheet.

Use HSMC_TIMINGS.TADL to configure the timing between the last address latch cycle and the first rising edge of WEN for data input.

Figure 16-27. Write Enable Timing Configuration

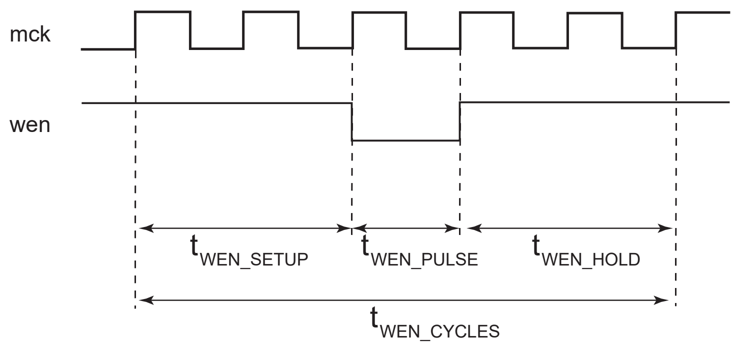


Figure 16-28. Write Enable Timing for NAND Flash Device Data Input Mode

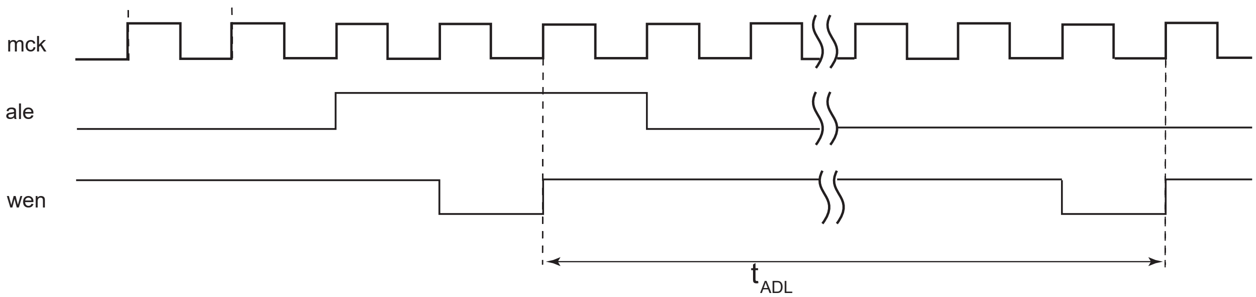


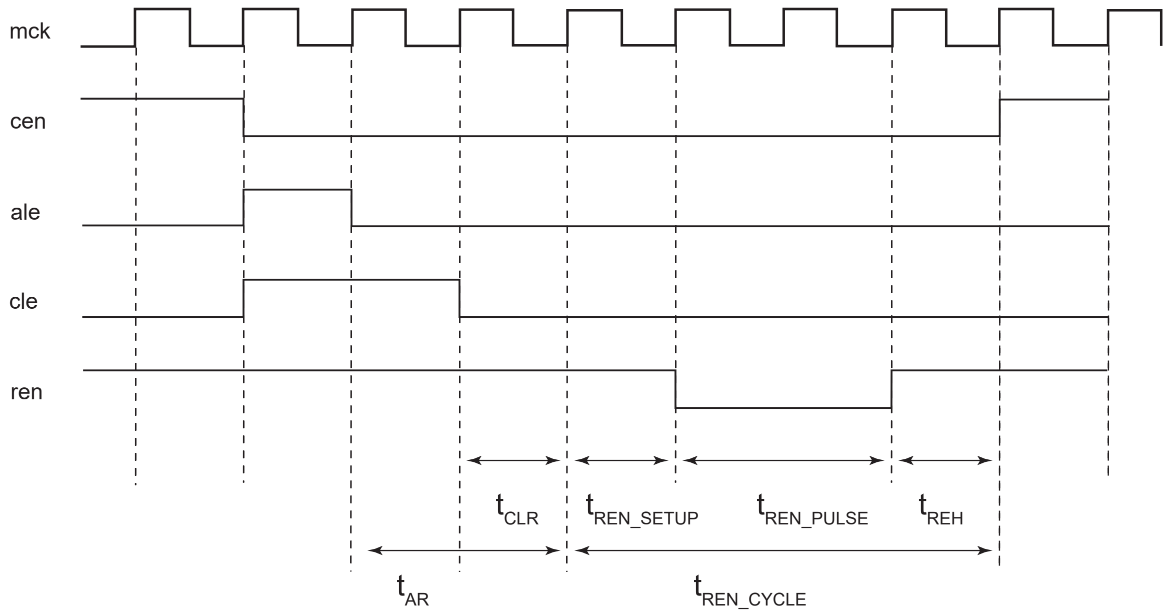
- Read Enable Configuration

Use NRD_SETUP, NRD_PULSE and NRD_CYCLE to define the read enable waveform according to the external device datasheet.

Use HSMC_TIMINGS.TAR to configure the timings between the address latch enable falling edge to read the enable falling edge.

Use HSMC_TIMINGS.TCLR to configure the timings between the command latch enable falling edge to read the enable falling edge.

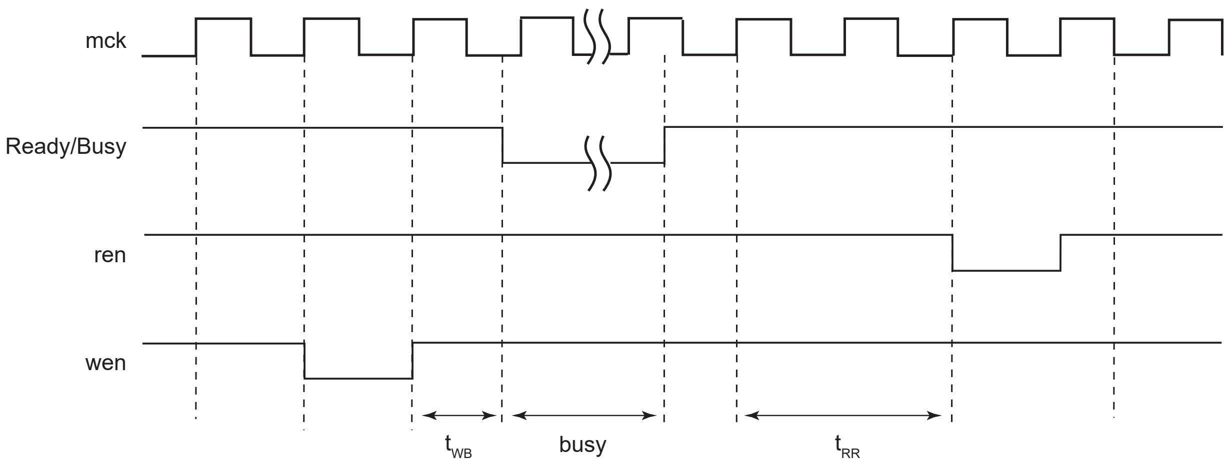
Figure 16-29. Read Enable Timing Configuration Working with NAND Flash Device



- Ready/Busy Signal Timing Configuration with a NAND Flash Device

Use HSMC_TIMINGS.TWB to configure the maximum elapsed time between the rising edge of the wen signal and the falling edge of the Ready/Busy signal. Use TRR field in the HSMC_TIMINGS register to program the number of clock cycles between the rising edge of the Ready/Busy signal and the falling edge of the ren signal.

Figure 16-30. Ready/Busy Timing Configuration

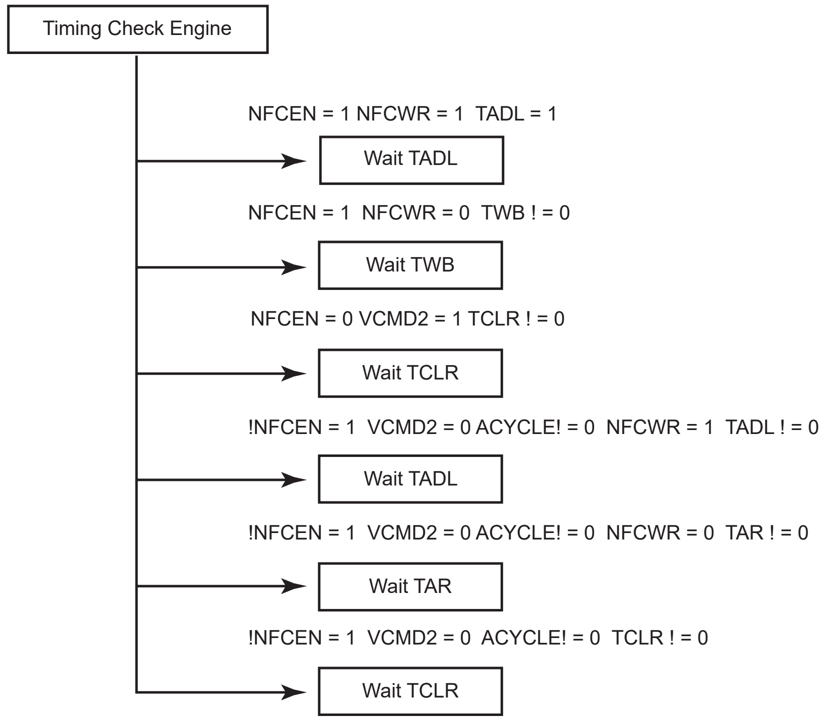


16.16.3.1 NFC Timing Engine

When the NFC Command register is written, the NFC issues a NAND Flash Command and optionally performs a data transfer between the NFC SRAM and the NAND Flash device. The NFC Timing Engine ensures valid NAND Flash timings, depending on the set of parameters decoded from the address bus. These timings are defined in the HSMC_TIMINGS register.

For information on the timing used depending on the command, see the figure below.

Figure 16-31. NFC Timing Engine



See the register descriptions NFCADDR_CMD and HSMC_TIMINGSx.

16.16.4 NFC SRAM

16.16.4.1 NFC SRAM Mapping

If the NFC is used to read and write data from and to the NAND Flash, the configuration depends on the page size (HSMC_CFG.PAGESIZE field). See the tables below for detailed mapping.

The NFC can handle the NAND Flash with a page size of 8 Kbytes or lower (2 Kbytes, for example). In case of a 4 Kbyte or lower page size, the NFC SRAM can be split into two banks. The HSMC_BANK.BANK bit is used to select where NAND Flash data are written or read. For an 8 Kbyte page size, this field is not relevant.

Note that a “Ping-Pong” mode (write or read to a bank while the NFC writes or reads to another bank) is accessible with the NFC (using two different banks).

If the NFC is not used, the NFC SRAM can be used for a general purpose by the application.

Table 16-8. NFC SRAM Bank Mapping for 512 bytes

Offset	Use	Access
0x00000000–0x000001FF	Main Area Bank 0	Read/Write
0x00000200–0x000003FF	Spare Area Bank 0	Read/Write
0x00001200–0x000013FF	Main Area Bank 1	Read/Write
0x00001400–0x000015FF	Spare Area Bank 1	Read/Write

Table 16-9. NFC SRAM Bank Mapping for 1 Kbyte

Offset	Use	Access
0x00000000–0x000003FF	Main Area Bank 0	Read/Write
0x00000400–0x000005FF	Spare Area Bank 0	Read/Write

...........continued

Offset	Use	Access
0x00001200–0x000015FF	Main Area Bank 1	Read/Write
0x00001600–0x000017FF	Spare Area Bank 1	Read/Write

Table 16-10. NFC SRAM Bank Mapping for 2 Kbytes

Offset	Use	Access
0x00000000–0x000007FF	Main Area Bank 0	Read/Write
0x00000800–0x000009FF	Spare Area Bank 0	Read/Write
0x00001200–0x000019FF	Main Area Bank 1	Read/Write
0x00001A00–0x00001BFF	Spare Area Bank 1	Read/Write

Table 16-11. NFC SRAM Bank Mapping for 4 Kbytes

Offset	Use	Access
0x00000000–0x00000FFF	Main Area Bank 0	Read/Write
0x00001000–0x000011FF	Spare Area Bank 0	Read/Write
0x00001200–0x000021FF	Main Area Bank 1	Read/Write
0x00002200–0x000023FF	Spare Area Bank 1	Read/Write

Table 16-12. NFC SRAM Bank Mapping for 8 Kbytes, only one bank is available

Offset	Use	Access
0x00000000–0x00001FFF	Main Area Bank 0	Read/Write
0x00002000–0x000023FF	Spare Area Bank 0	Read/Write

16.16.4.2 NFC SRAM Access Prioritization Algorithm

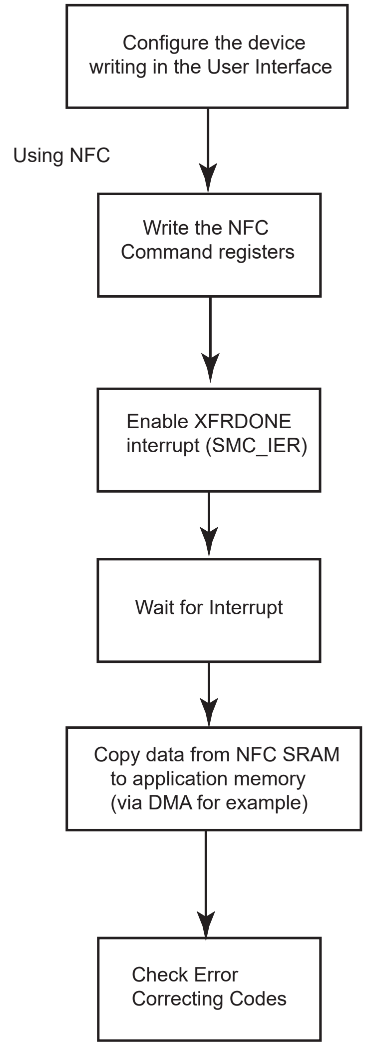
When the NFC is reading from or writing to an NFC SRAM bank, the other bank is available. If an NFC SRAM access occurs when the NFC performs a read or write operation in the same bank, then the access is discarded. The write operation is not performed. The read operation returns undefined data. If this situation is encountered, the AWB status flag located in the NFC Status Register is raised and indicates that a shared resource access violation has occurred.

16.16.5 NAND Flash Operations

This section describes the software operations needed to issue commands to the NAND Flash device and to perform data transfers using the NFC.

16.16.5.1 Page Read

Figure 16-32. Page Read Flow Chart

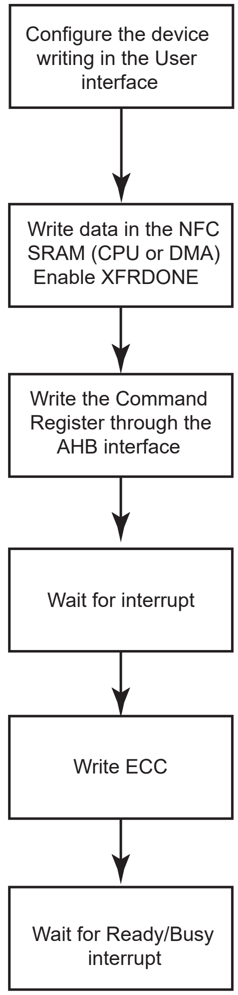


Instead of using the interrupt, the NFCBUSY flag can be polled.

For more information on the NFC Control register, see NFCADDR_CMD.

16.16.5.2 Program Page

Figure 16-33. Program Page Flow Chart



Writing the ECC cannot be done using the NFC; it needs to be done “manually”.

Instead of using the interrupt, the NFCBUSY flag can be polled.

For more information on the NFC Control register, see NFCADDR_CMD.

16.17 PMECC Controller Functional Description

The Programmable Multibit Error Correcting Code (PMECC) controller is a programmable binary BCH (Bose, Chaudhuri and Hocquenghem) encoder/decoder. This controller can be used to generate redundancy information for both SLC and MLC NAND devices. It supports redundancy for correction of 2, 4, 8, 12, 24 or 32 errors per sector of data. The sector size is programmable and can be set to 512 bytes or 1024 bytes. The PMECC module generates redundancy at encoding time, when a NAND write page operation is performed. The redundancy is appended to the page and written in the spare area. This operation is performed by the processor. It moves the content of the PMECCX registers into the NAND Flash memory. The number of registers depends on the selected error correction capability (see the table Relevant Redundancy Registers). This operation is executed for each sector. At decoding time, the PMECC module generates the remainders of the received codeword by the minimal polynomials. When all remainders for a given sector are set to zero, no error occurred. When the remainders are different from zero, the codeword is corrupted and further processing is required.

The PMECC module generates an interrupt indicating that an error occurred. The processor must read the PMECC Interrupt Status register (HSMC_PMECCISR). This register indicates which sector is corrupted.

The processor must execute the following decoding steps to find the error location within a sector:

1. Compute syndrome
2. Find the error location polynomial
3. Find the roots of the error location polynomial

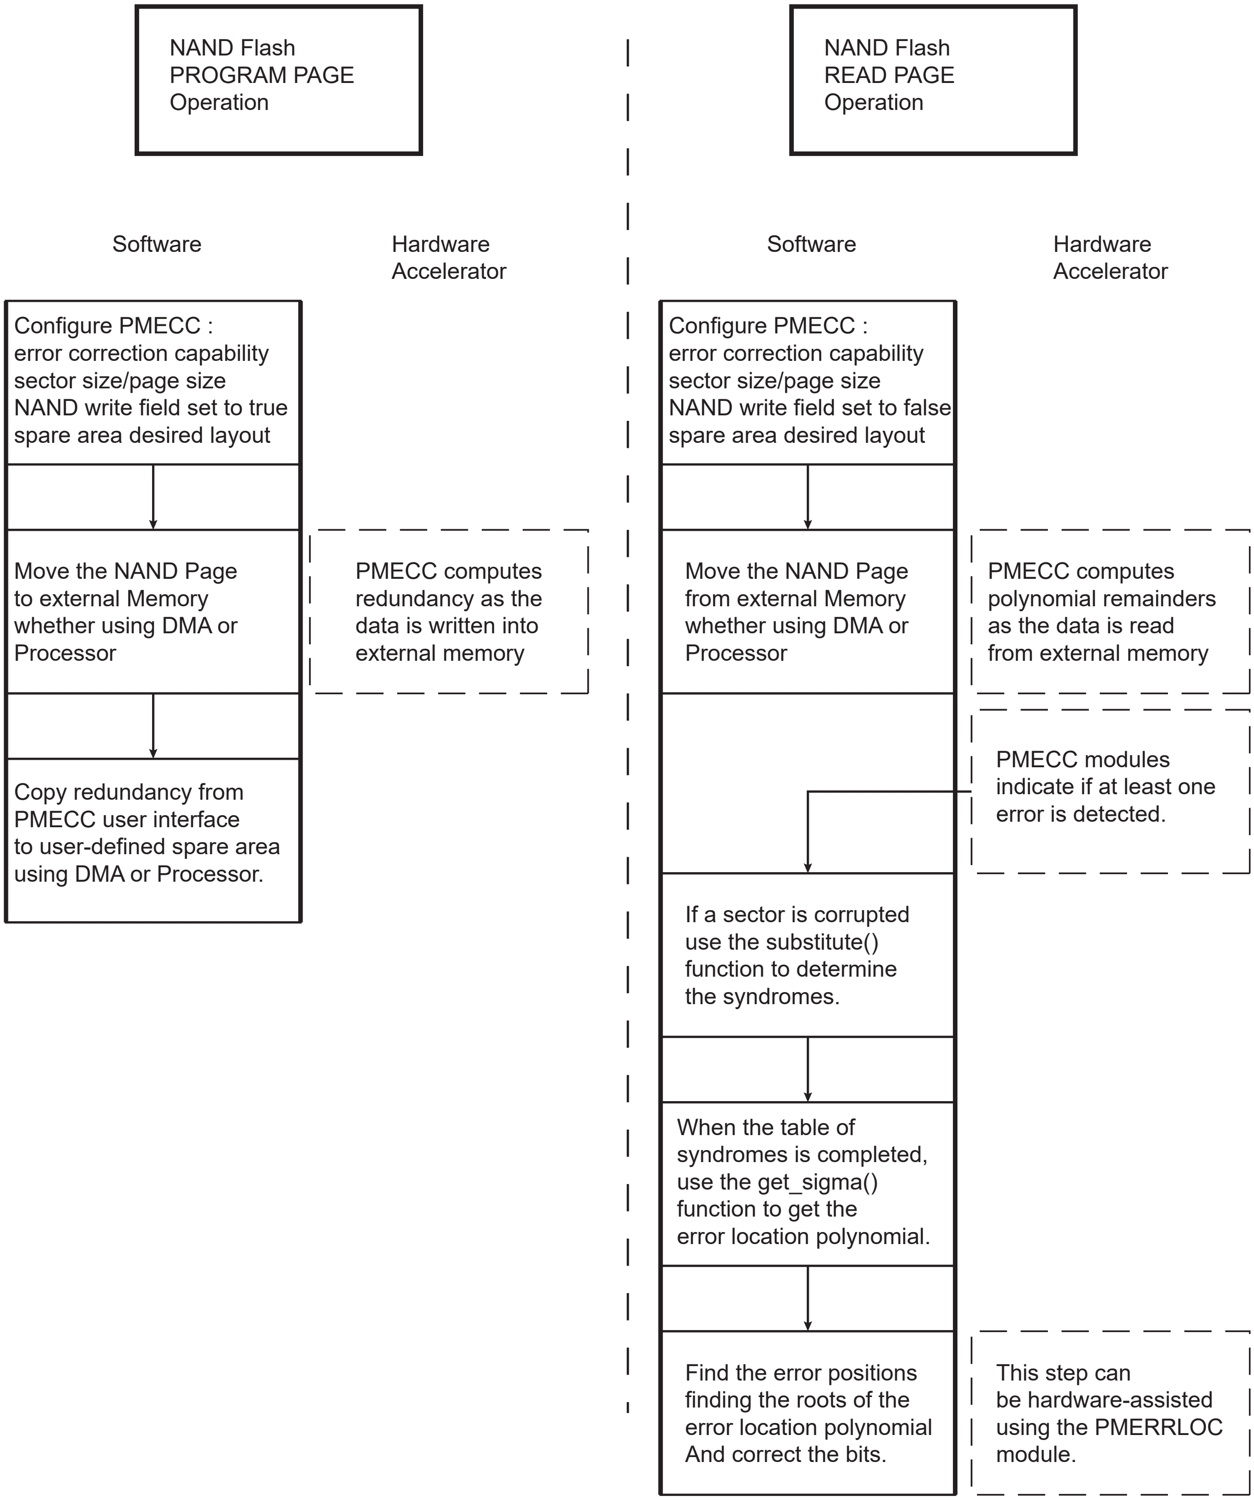
All decoding steps involve finite field computation. It means that a library of finite field arithmetic must be available to perform addition, multiplication and inversion. These arithmetic operations can be performed through the use of a memory mapped lookup table, or direct software implementation. The software implementation presented is based on lookup tables. Two tables named gf_log and gf_antilog are used. If alpha is the primitive element of the field, then a power of alpha is in the field. Assuming that beta = alpha ^ index, then beta belongs to the field, and gf_log(beta) = gf_log(alpha ^ index) = index. The gf_antilog table provides exponent inverse of the element; if beta = alpha ^ index, then gf_antilog(index) = beta.

The first step consists in the syndrome computation. The PMECC module computes the remainders and the software must substitute the power of the primitive element. The procedure implementation is given in the section Remainder Substitution Procedure.

The second step is the most software intensive. It is the Berlekamp's iterative algorithm for finding the error-location polynomial. The procedure implementation is given in the section Finding the Error Location Polynomial Sigma(x).

The Last step is finding the root of the error location polynomial. This step can be very software intensive. Indeed there is no straightforward method of finding the roots, except evaluating each element of the field in the error location polynomial. However, a hardware accelerator can be used to find the roots of the polynomial. The PMERRLOC module provides this kind of hardware acceleration.

Figure 16-34. Software Hardware Multibit Error Correction Dataflow



16.17.1 MLC/SLC Write Page Operation Using PMECC

When an MLC write page operation is performed, the PMECC controller is configured with the NANDWR bit of the PMECC Configuration (HSMC_PMECCFG) register set to one. When the NAND spare area contains file system information and redundancy (PMECCx), the spare area is error-protected, then the HSMC_PMECCFG.SPAREEN bit is set. When the NAND spare area contains only redundancy information, the SPAREEN bit is cleared.

When the write page operation is terminated, the user writes the redundancy in the NAND spare area. This operation can be done with DMA assistance.

Table 16-13. Relevant Redundancy Registers

BCH_ERR Field	Sector Size Set to 512 Bytes	Sector Size Set to 1024 Bytes
0	PMECC0	PMECC0
1	PMECC0, PMECC1	PMECC0, PMECC1
2	PMECC0, PMECC1, PMECC2, PMECC3	PMECC0, PMECC1, PMECC2, PMECC3
3	PMECC0, PMECC1, PMECC2, PMECC3, PMECC4, PMECC5, PMECC6	PMECC0, PMECC1, PMECC2, PMECC3, PMECC4, PMECC5, PMECC6
4	PMECC0, PMECC1, PMECC2, PMECC3, PMECC4, PMECC5, PMECC6, PMECC7, PMECC8, PMECC9	PMECC0, PMECC1, PMECC2, PMECC3, PMECC4, PMECC5, PMECC6, PMECC7, PMECC8, PMECC9, PMECC10
5	PMECC0, PMECC1, PMECC2, PMECC3, PMECC4, PMECC5, PMECC6, PMECC7, PMECC8, PMECC9, PMECC10, PMECC11, PMECC12	PMECC0, PMECC1, PMECC2, PMECC3, PMECC4, PMECC5, PMECC6, PMECC7, PMECC8, PMECC9, PMECC10, PMECC11, PMECC12, PMECC13

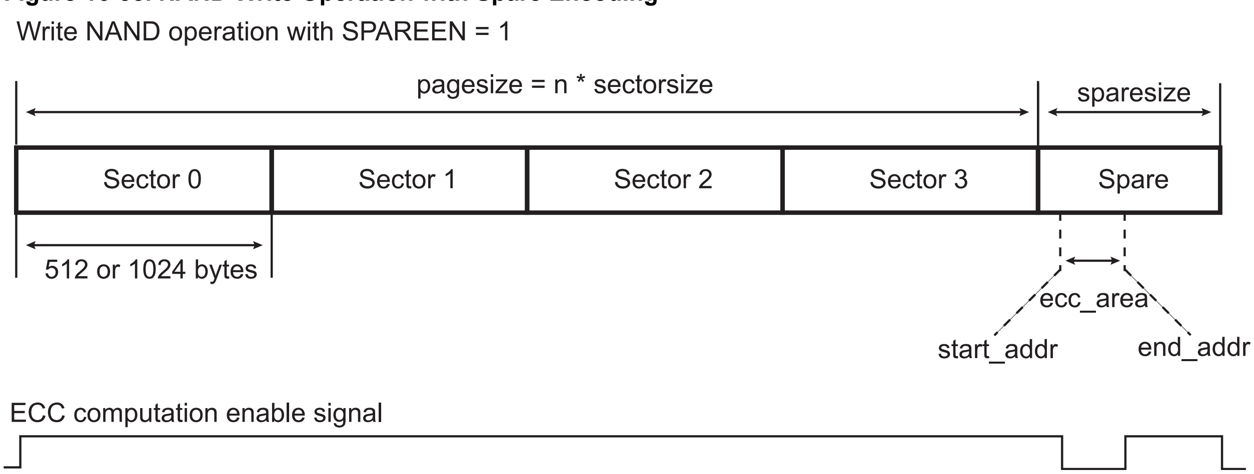
Table 16-14. Number of Relevant ECC Bytes per Sector, Copied from LSByte to MSByte

BCH_ERR Field	Sector Size Set to 512 Bytes	Sector Size Set to 1024 Bytes
0	4 bytes	4 bytes
1	7 bytes	7 bytes
2	13 bytes	14 bytes
3	20 bytes	21 bytes
4	39 bytes	42 bytes
5	52 bytes	56 bytes

16.17.1.1 SLC/MLC Write Operation with Spare Enable Bit Set

When PMECCFG.SPAREEN is set, the spare area of the page is encoded with the data stream of the last sector of the page. This mode is entered by setting PMECCTRL.DATA. When the encoding process is over, the redundancy is written to the spare area in User mode. PMECCTRL.USER must be set.

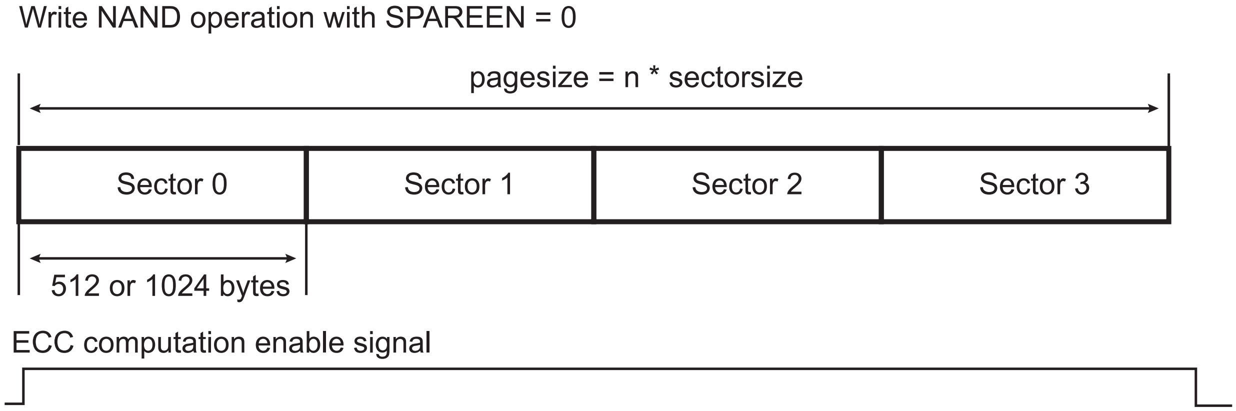
Figure 16-35. NAND Write Operation with Spare Encoding



16.17.1.2 SLC/MLC Write Operation with Spare Disable

When PMECCFG.SPAREEN is cleared, the spare area is not encoded with the data stream. This mode is entered by setting PMECCTRL.DATA.

Figure 16-36. NAND Write Operation



16.17.2 MLC/SLC Read Page Operation Using PMECC

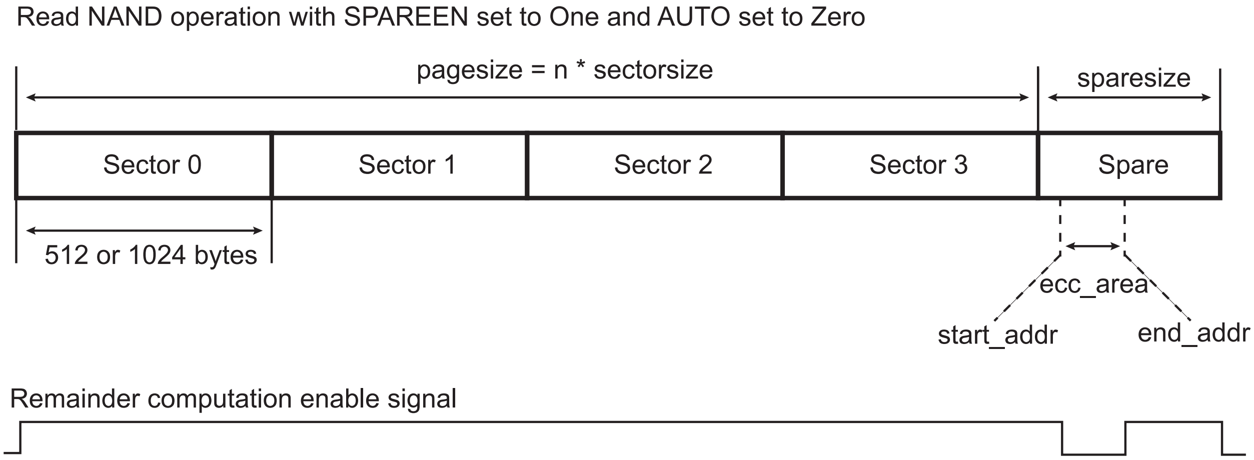
Table 16-15. Relevant Remainder Registers

BCH_ERR Field	Sector Size Set to 512 Bytes	Sector Size Set to 1024 Bytes
0	PMECCREM0	PMECCREM0
1	PMECCREM0, PMECCREM1	PMECCREM0, PMECCREM1
2	PMECCREM0, PMECCREM1, PMECCREM2, PMECCREM3	PMECCREM0, PMECCREM1, PMECCREM2, PMECCREM3
3	PMECCREM0, PMECCREM1, PMECCREM2, PMECCREM3, PMECCREM4, PMECCREM5, PMECCREM6, PMECCREM7	PMECCREM0, PMECCREM1, PMECCREM2, PMECCREM3, PMECCREM4, PMECCREM5, PMECCREM6, PMECCREM7
4	PMECCREM0, PMECCREM1, PMECCREM2, PMECCREM3, PMECCREM4, PMECCREM5, PMECCREM6, PMECCREM7, PMECCREM8, PMECCREM9, PMECCREM10, PMECCREM11	PMECCREM0, PMECCREM1, PMECCREM2, PMECCREM3, PMECCREM4, PMECCREM5, PMECCREM6, PMECCREM7, PMECCREM8, PMECCREM9, PMECCREM10, PMECCREM11
5	PMECCREM0, PMECCREM1, PMECCREM2, PMECCREM3, PMECCREM4, PMECCREM5, PMECCREM6, PMECCREM7, PMECCREM8, PMECCREM9, PMECCREM10, PMECCREM11, PMECCREM12, PMECCREM13, PMECCREM14, PMECCREM15	PMECCREM0, PMECCREM1, PMECCREM2, PMECCREM3, PMECCREM4, PMECCREM5, PMECCREM6, PMECCREM7, PMECCREM8, PMECCREM9, PMECCREM10, PMECCREM11, PMECCREM12, PMECCREM13, PMECCREM14, PMECCREM15

16.17.2.1 MLC/SLC Read Operation with Spare Decoding

When the spare area is protected, it contains valid data. As redundancy may be included in the middle of the information stream, program the start address and the end address of the ECC area. The controller will automatically skip the ECC area. To enter this mode, write a 1 in HSMC_PMECCTRL.DATA. When the page is fully retrieved from the NAND, the ECC area is read in User mode (write a 1 to PMECCTRL.USER to enter User mode).

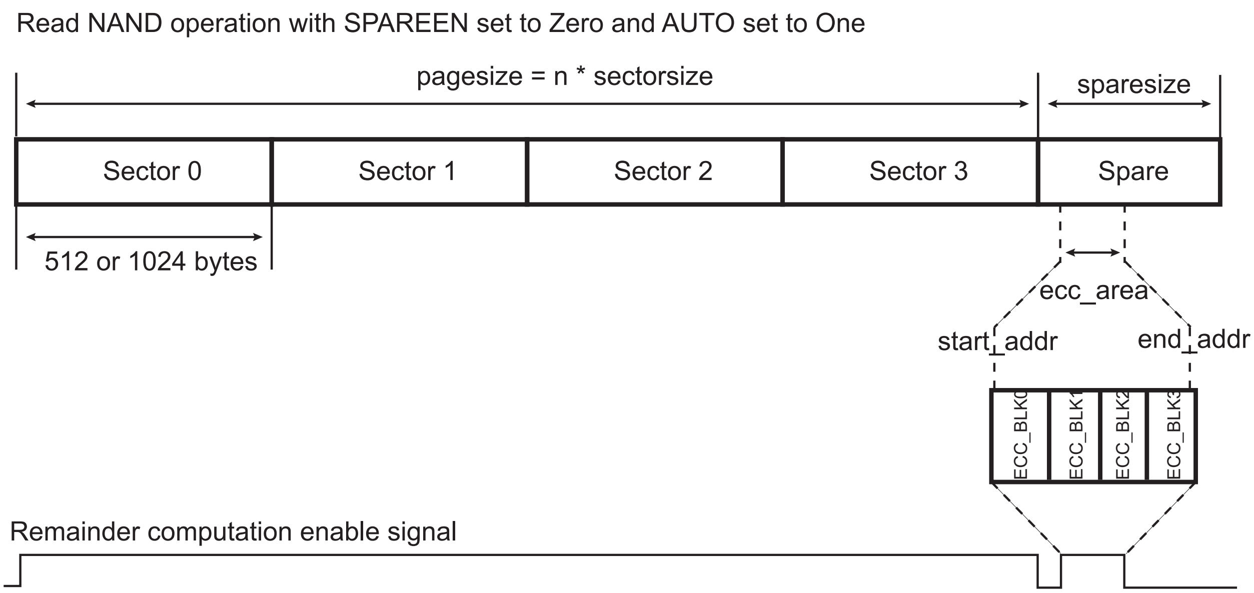
Figure 16-37. Read Operation with Spare Decoding



16.17.2.2 MLC/SLC Read Operation

If the spare area is not protected with the error correcting code, the redundancy area is retrieved directly. To enter this mode, write a 1 in PMECCTRL.DATA. When the AUTO field is set to one, the ECC is retrieved automatically; otherwise, read ECC via User mode.

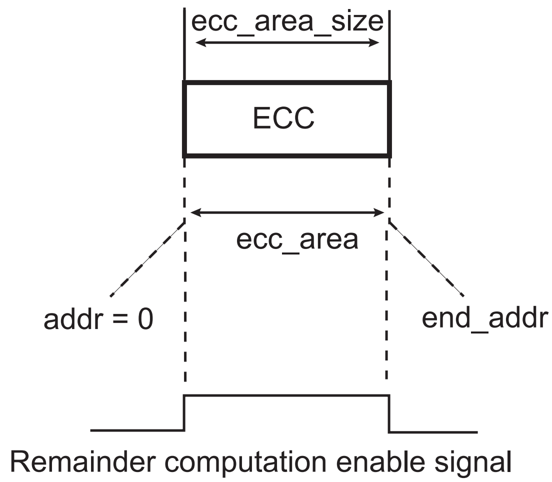
Figure 16-38. Read Operation



16.17.2.3 MLC/SLC User Read ECC Area

This mode allows a manual retrieve of the ECC. To enter the mode, write a 1 in PMECCTRL.USER.

Figure 16-39. Read User Mode



16.17.2.4 MLC Controller Working with NFC

Table 16-16. MLC Controller Configuration when the Host Controller is Used

Transfer Type	NFC		PMECC		
	RSPARE	WSPARE	SPAREEN	AUTO	User Mode
Program Page main area is protected, spare is not protected, spare is written manually	0	0	0	0	Not used
Program Page main area is protected, spare is protected, spare is written by NFC	0	1	1	0	Not used
Read Page main area is protected, spare is not protected, spare is not retrieved by NFC	0	0	0	0	Used
Read Page main area is protected, spare is not protected, spare is retrieved by NFC	1	0	0	1	Not used
Read Page main area is protected, spare is protected, spare is retrieved by NFC	1	0	1	0	Used

16.18 Software Implementation

16.18.1 Remainder Substitution Procedure

The substitute function evaluates the remainder polynomial, with different values of the field primitive element. The addition arithmetic operation is performed with the exclusive OR. The multiplication arithmetic operation is performed through the gf_log and gf_antilog lookup tables.

The REM2NP1 and REMN2NP3 fields of the PMECCREMN registers contain only odd remainders. Each bit indicates whether the coefficient of the remainder polynomial is set to zero or not.

NB_ERROR_MAX defines the maximum value of the error correcting capability.

NB_ERROR defines the error correcting capability selected at encoding/decoding time.

NB_FIELD_ELEMENTS defines the number of elements in the field.

si[] is a table that holds the current syndrome value. An element of that table belongs to the field. This is also a shared variable for the next step of the decoding operation.

oo[] is a table that contains the degree of the remainders.

```
int substitute()
{
int i;
int j;
for (i = 1; i < 2 * NB_ERROR_MAX; i++)
{
   si[i] = 0;
}
for (i = 1; i < 2*NB_ERROR; i++)
{
   for (j = 0; j < oo[i]; j++)
 {
     if (REM2NPX[i][j])
    {
      si[i] = gf_antilog[(i * j)%NB_FIELD_ELEMENTS] ^ si[i];
     }
   }
}
return 0;
}
```

16.18.2 Finding the Error Location Polynomial Sigma(x)

The sample code below gives a Berlekamp iterative procedure for finding the value of the error location polynomial.

The input of the procedure is the si[] table defined in the remainder substitution procedure.

The output of the procedure is the error location polynomial named smu (sigma mu). The polynomial coefficients belong to the field. The smu[NB_ERROR+1][] is a table that contains all these coefficients.

NB_ERROR_MAX defines the maximum value of the error correcting capability.

NB_ERROR defines the error correcting capability selected at encoding/decoding time.

NB_FIELD_ELEMENTS defines the number of elements in the field.

```
int get_sigma()
    {
    int i;
    int j;
    int k;
    /* mu          */
    int mu[NB_ERROR_MAX+2];
    /* sigma ro    */
    int sro[2*NB_ERROR_MAX+1];
    /* discrepancy */
    int dmu[NB_ERROR_MAX+2];
    /* delta order   */
    int delta[NB_ERROR_MAX+2];
    /* index of largest delta */
    int ro;
    int largest;
    int diff;

16.18.3 Finding the Error Position

The output of the get_sigma() procedure is a polynomial stored in the smu[NB_ERROR+1][] table. The error positions are the roots of that polynomial. The degree of that polynomial is a very important information, as it gives the number of errors. The PMERRLOC module provides hardware accelerator for that step.

16.18.3.1 Error Location

The PMECC Error Location controller provides hardware acceleration for determining roots of polynomials over two finite fields: GF(2^13) and GF(2^14). It integrates 32 fully programmable coefficients. These coefficients belong to GF(2^13) or GF(2^14). The coefficient programmed in PMERRLOC{i} is the coefficient of X ^ i in the polynomial.

The search operation is started as soon as a write access is detected in the PMECC Error Location Enable (HSMC_ELEN) register and can be disabled by writing to the PMECC Error Location Disable (HSMC_ELDIS) register. Initialize HSMC_ELEN.ENINIT with the number of galois field elements to test.

Table 16-17. ENINIT Field Value for a Sector Size of 512 Bytes

Error Correcting Capability	ENINIT Value
2	4122
4	4148
8	4200
12	4252
24	4408
32	4512

Table 16-18. ENINIT Field Value for a Sector Size of 1024 Bytes

Error Correcting Capability	ENINIT Value
2	8220
4	8248
8	8304

...........continued

Error Correcting Capability	ENINIT Value
12	8360
24	8528
32	8640

While the PMECC engine searches for roots, the BUSY field in the PMECC Error Location Status register (HSMC_ELSR) remains asserted. An interrupt is asserted at the end of the computation, and the DONE bit in the PMECC Error Location Interrupt Status register (HSMC_ELSIR) is set. The HSMC_ELISR.ERR_CNT field shows the number of errors. The PMECC Error Location x registers (HSMC_ERRLOCx) show the error position.

16.19 Register Summary

Notes: The following blocks of registers are instanced 8 times in the user interface:

- HSMC_PMECCx[x=0..13]
- HSMCC_REMx[x=0..15]

Bits 30:24 – NFCSPARESIZE[6:0] NAND Flash Spare Area Size Retrieved by the Host Controller
The spare size is set to (NFCSPARESIZE + 1) * 4 bytes. The spare area is only retrieved when RSPARE or WSPARE is activated.

Bits 22:20 – DTOMUL[2:0] Data Timeout Multiplier
These fields determine the maximum number of main system bus clock cycles that the SMC waits until the detection of a rising edge on Ready/Busy signal.
If the data timeout set by DTOCYC and DTOMUL has been exceeded, the Data Timeout Error flag (DTOE) in the NFC Status Register (NFC_SR) raises.
Data Timeout Multiplier is defined by DTOMUL as shown in the following table:

Value	Name	Description
0	X1	DTOCYC
1	X16	DTOCYC x 16
2	X128	DTOCYC x 128
3	X256	DTOCYC x 256
4	X1024	DTOCYC x 1024
5	X4096	DTOCYC x 4096
6	X65536	DTOCYC x 65536
7	X1048576	DTOCYC x 1048576

Bits 19:16 – DTOCYC[3:0] Data Timeout Cycle Number

Bit 13 – RBEDGE Ready/Busy Signal Edge Detection

Value	Description
0	Indicates the level of the Ready/Busy line.
1	Indicates that a transition has occurred on the Ready/Busy line.

Bit 12 – EDGECTRL Rising/Falling Edge Detection Control

Value	Description
0	Rising edge is detected.
1	Falling edge is detected.

Bit 9 – RSPARE Read Spare Area

Value	Description
0	The NFC skips the spare area in Read mode.
1	The NFC reads both main area and spare area in Read mode.

Bit 8 – WSPARE Write Spare Area

Value	Description
0	The NFC skips the spare area in Write mode.
1	The NFC writes both main area and spare area in Write mode.

Bits 2:0 – PAGESIZE[2:0] Page Size of the NAND Flash Device

Value	Name	Description
0	PS512	Main area 512 bytes
1	PS1024	Main area 1024 bytes
2	PS2048	Main area 2048 bytes
3	PS4096	Main area 4096 bytes
4	PS8192	Main area 8192 bytes

16.19.2 NFC Control Register

Name: HSMC_CTRL
Offset: 0x004
Reset: –
Property: Write-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
							NFCDIS	NFCEN
Access							W	W
Reset							–	–

Bit 1 – NFCDIS NAND Flash Controller Disable

Value	Description
0	No effect.
1	Disables the NAND Flash controller.

Bit 0 – NFCEN NAND Flash Controller Enable

Value	Description
0	No effect.
1	Enables the NAND Flash controller.

16.19.3 NFC Status Register

Name: HSMC_SR
Offset: 0x008
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
								RB_EDGE0
Access								R
Reset								0

Bit	23	22	21	20	19	18	17	16
	NFCASE	AWB	UNDEF	DTOE			CMDDONE	XFRDONE
Access	R	R	R	R			R	R
Reset	0	0	0	0			0	0

Bit	15	14	13	12	11	10	9	8
		NFCSID[2:0]			NFCWR			NFCBUSY
Access		R	R	R	R			R
Reset		0	0	0	0			0

Bit	7	6	5	4	3	2	1	0
			RB_FALL	RB_RISE				SMCSTS
Access			R	R				R
Reset			0	0				0

Bit 24 – RB_EDGE0 Ready/Busy Line 0 Edge Detected
If set to one, this flag indicates that an edge has been detected on the Ready/Busy Line 0. Depending on HSMC_CFG.EDGECTRL, only the rising or the falling edge is detected. This flag is reset after a Status Read operation.

Bit 23 – NFCASE NFC Access Size Error
If set to one, this flag indicates that an illegal access has been detected in the NFC Memory Area. Only Word access is allowed within the NFC memory area. This flag is reset after a Status Read operation.

Bit 22 – AWB Accessing While Busy
If set to one, this flag indicates that an AHB host has performed an access during the busy phase. This flag is reset after a Status Read operation.

Bit 21 – UNDEF Undefined Area Error
When set to one, this flag indicates that the processor performed an access in an undefined memory area. This flag is reset after a Status Read operation.

Bit 20 – DTOE Data Timeout Error
When set to one, this flag indicates that the data timeout set by DTOMUL and DTOCYC has been exceeded. This flag is reset after a Status Read operation.

Bit 17 – CMDDONE Command Done
When set to one, this flag indicates that the NFC has terminated the command. This flag is reset after a Status Read operation.

Bit 16 – XFRDONE NFC Data Transfer Terminated
When set to one, this flag indicates that the NFC has terminated the data transfer. This flag is reset after a Status Read operation.

Bits 14:12 – NFCSID[2:0] NFC Chip Select ID (this field cannot be reset)
When a command is issued, this field indicates the value of the targeted chip select.

Bit 11 – NFCWR NFC Write/Read Operation (this field cannot be reset)
When a command is issued, this field indicates the current Read or Write operation.

Bit 8 – NFCBUSY NFC Busy (this field cannot be reset)
When set to one, this flag indicates that the controller is activated and accesses the memory device.

Bit 5 – RB_FALL Selected Ready Busy Falling Edge Detected
When set to one, this flag indicates that a falling edge on the Ready/Busy Line has been detected. This flag is reset after a Status Read operation. The Ready/Busy line is selected through the decoding of field HSMC_SR.NFCSID.

Bit 4 – RB_RISE Selected Ready Busy Rising Edge Detected
When set to one, this flag indicates that a rising edge on the Ready/Busy Line has been detected. This flag is reset after a Status Read operation. The Ready/Busy line is selected through the decoding of field HSMC_SR.NFCSID.

Bit 0 – SMCSTS NAND Flash Controller Status (this field cannot be reset)

Value	Description
0	The NAND Flash controller is disabled.
1	The NAND Flash controller is enabled.

16.19.4 NFC Interrupt Enable Register

Name: HSMC_IER
Offset: 0x00C
Reset: –
Property: Write-only

The following configuration values are valid for all listed bit names of this register:
0: No effect.

1: Enables the corresponding interrupt.

Bit	31	30	29	28	27	26	25	24
								RB_EDGE0
Access								W
Reset								–

Bit	23	22	21	20	19	18	17	16
	NFCASE	AWB	UNDEF	DTOE			CMDDONE	XFRDONE
Access	W	W	W	W			W	W
Reset	–	–	–	–			–	–

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
			RB_FALL	RB_RISE				
Access			W	W				
Reset			–	–				

Bit 24 – RB_EDGE0 Ready/Busy Line 0 Interrupt Enable

Bit 23 – NFCASE NFC Access Size Error Interrupt Enable

Bit 22 – AWB Accessing While Busy Interrupt Enable

Bit 21 – UNDEF Undefined Area Access Interrupt Enable

Bit 20 – DTOE Data Timeout Error Interrupt Enable

Bit 17 – CMDDONE Command Done Interrupt Enable

Bit 16 – XFRDONE Transfer Done Interrupt Enable

Bit 5 – RB_FALL Ready Busy Falling Edge Detection Interrupt Enable

Bit 4 – RB_RISE Ready Busy Rising Edge Detection Interrupt Enable

16.19.5 NFC Interrupt Disable Register

Name: HSMC_IDR
Offset: 0x010
Reset: –
Property: Write-only

The following configuration values are valid for all listed bit names of this register:
0: No effect.

1: Disables the corresponding interrupt.

Bit	31	30	29	28	27	26	25	24
								RB_EDGE0
Access								W
Reset								–

Bit	23	22	21	20	19	18	17	16

Access	W	W	W	W			W	W
Reset	–	–	–	–			–	–

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
			RB_FALL	RB_RISE				
Access			W	W				
Reset			–	–				

Bit 24 – RB_EDGE0 Ready/Busy Line 0 Interrupt Disable

Bit 23 – NFCASE NFC Access Size Error Interrupt Disable

Bit 22 – AWB Accessing While Busy Interrupt Disable

Bit 21 – UNDEF Undefined Area Access Interrupt Disable

Bit 20 – DTOE Data Timeout Error Interrupt Disable

Bit 17 – CMDDONE Command Done Interrupt Disable

Bit 16 – XFRDONE Transfer Done Interrupt Disable

Bit 5 – RB_FALL Ready Busy Falling Edge Detection Interrupt Disable

Bit 4 – RB_RISE Ready Busy Rising Edge Detection Interrupt Disable

16.19.6 NFC Interrupt Mask Register

Name: HSMC_IMR
Offset: 0x014
Reset: 0x00000000
Property: Read-only

The following configuration values are valid for all listed bit names of this register:
0: Disables the corresponding interrupt.

1: Enables the corresponding interrupt.

Bit	31	30	29	28	27	26	25	24
								RB_EDGE0
Access								R
Reset								0
Bit	23	22	21	20	19	18	17	16
	NFCASE	AWB	UNDEF	DTOE			CMDDONE	XFRDONE
Access	R	R	R	R			R	R
Reset	0	0	0	0			0	0
Bit	15	14	13	12	11	10	9	8
Access								
Reset								
Bit	7	6	5	4	3	2	1	0
			RB_FALL	RB_RISE				
Access			R	R				
Reset			0	0				

Bit 24 – RB_EDGE0 Ready/Busy Line 0 Interrupt Mask

Bit 23 – NFCASE NFC Access Size Error Interrupt Mask

Bit 22 – AWB Accessing While Busy Interrupt Mask

Bit 21 – UNDEF Undefined Area Access Interrupt Mask5

Bit 20 – DTOE Data Timeout Error Interrupt Mask

Bit 17 – CMDDONE Command Done Interrupt Mask

Bit 16 – XFRDONE Transfer Done Interrupt Mask

Bit 5 – RB_FALL Ready Busy Falling Edge Detection Interrupt Mask

Bit 4 – RB_RISE Ready Busy Rising Edge Detection Interrupt Mask

16.19.7 NFC Address Cycle Zero Register

Name: HSMC_ADDR
Offset: 0x018
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
	ADDR_CYCLE0[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 7:0 – ADDR_CYCLE0[7:0] NAND Flash Array Address Cycle 0
When five address cycles are used, ADDR_CYCLE0 is the first byte written to the NAND Flash (used by the NFC).

16.19.8 NFC Bank Register

Name: HSMC_BANK
Offset: 0x01C
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
								BANK
Access								R/W
Reset								0

Bit 0 – BANK Bank Identifier

Value	Description
0	Bank 0 is used.
1	Bank 1 is used.

16.19.9 PMECC Configuration Register

Name: HSMC_PMECCFG
Offset: 0x070
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
				AUTO				SPAREEN
Access				R/W				R/W
Reset				0				0

Bit	15	14	13	12	11	10	9	8
				NANDWR			PAGESIZE[1:0]	
Access				R/W			R/W	R/W
Reset				0			0	0

Bit	7	6	5	4	3	2	1	0
				SECTORSZ		BCH_ERR[2:0]		
Access				R/W		R/W	R/W	R/W
Reset				0		0	0	0

Bit 20 – AUTO Automatic Mode Enable
This bit is only relevant in NAND Read mode, when HSMC_PMECCFG.SPAREEN=0 and HSMC_CFG.RSPARE=1.

Value	Description
0	Indicates that the ECC computation is not retrieved automatically and must be read via User mode.
1	Indicates that the ECC computation is retrieved automatically via Data mode.

Bit 16 – SPAREEN Spare Enable
For NAND write access:
0: The spare area is not protected by ECC.
1: The spare area is protected with the last sector of data.
For NAND read access:
0: The spare area is not protected by ECC.
1: The spare area contains protected data.

Bit 12 – NANDWR NAND Write Access

Value	Description
0	NAND read access.
1	NAND write access.

Bits 9:8 – PAGESIZE[1:0] Number of Sectors in the Page

Value	Name	Description
0	PAGESIZE_1SEC	1 sector for main area (512 or 1024 bytes).
1	PAGESIZE_2SEC	2 sectors for main area (1024 or 2048 bytes).
2	PAGESIZE_4SEC	4 sectors for main area (2048 or 4096 bytes).
3	PAGESIZE_8SEC	8 sectors for main area (4096 or 8192 bytes).

Bit 4 – SECTORSZ Sector Size

Value	Description
0	The ECC computation is based on a sector of 512 bytes.

Value	Description
1	The ECC computation is based on a sector of 1024 bytes.

Bits 2:0 – BCH_ERR[2:0] Error Correcting Capability

Value	Name	Description
0	BCH_ERR2	2 errors
1	BCH_ERR4	4 errors
2	BCH_ERR8	8 errors
3	BCH_ERR12	12 errors
4	BCH_ERR24	24 errors
5	BCH_ERR32	32 errors

16.19.10 PMECC Spare Area Size Register

Name: HSMC_PMECCSAREA
Offset: 0x074
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								
Bit	23	22	21	20	19	18	17	16
Access								
Reset								
Bit	15	14	13	12	11	10	9	8
								SPARESIZE[8]
Access								R/W
Reset								0
Bit	7	6	5	4	3	2	1	0
	SPARESIZE[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 8:0 – SPARESIZE[8:0] Spare Area Size
Number of bytes in the spare area. The spare area size is equal to (SPARESIZE + 1) bytes.

16.19.11 PMECC Start Address Register

Name: HSMC_PMECCSADDR
Offset: 0x078
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
								STARTADDR[8]
Access								R/W
Reset								0

Bit	7	6	5	4	3	2	1	0
	STARTADDR[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 8:0 – STARTADDR[8:0] ECC Area Start Address
This register is programmed with the start ECC start address. When STARTADDR is equal to 0, then the first ECC byte is located at the first byte of the spare area.

16.19.12 PMECC End Address Register

Name: HSMC_PMECCEADDR
Offset: 0x07C
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
								ENDADDR[8]
Access								R/W
Reset								0

Bit	7	6	5	4	3	2	1	0
	ENDADDR[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 8:0 – ENDADDR[8:0] ECC Area End Address
This register is programmed with the start ECC end address. When ENDADDR is equal to N, then the first ECC byte is located at byte N of the spare area.

16.19.13 PMECC Control Register

Name: HSMC_PMECCTRL
Offset: 0x084
Reset: –
Property: Write-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
			DISABLE	ENABLE		USER	DATA	RST
Access			W	W		W	W	W
Reset			–	–		–	–	–

Bit 5 – DISABLE PMECC Enable

Value	Description
0	No effect.
1	Disables the PMECC controller.

Bit 4 – ENABLE PMECC Enable

Value	Description
0	No effect.
1	Enables the PMECC controller.

Bit 2 – USER Start a User Mode Phase

Value	Description
0	No effect.
1	The PMECC controller enters a User mode phase.

Bit 1 – DATA Start a Data Phase

Value	Description
0	No effect.
1	The PMECC controller enters a Data phase.

Bit 0 – RST Reset the PMECC Module

Value	Description
0	No effect.
1	Resets the PMECC controller.

16.19.14 PMECC Status Register

Name: HSMC_PMECCSR
Offset: 0x088
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
				ENABLE				BUSY
Access				R				R
Reset				0				0

Bit 4 – ENABLE PMECC Enable Bit

Value	Description
0	PMECC controller disabled.
1	PMECC controller enabled.

Bit 0 – BUSY PMECC Kernel is Busy

Value	Description
0	PMECC controller finite state machine reached idle state.
1	PMECC controller finite state machine is processing the incoming byte stream.

16.19.15 PMECC Interrupt Enable Register

Name: HSMC_PMECCIER
Offset: 0x08C
Reset: –
Property: Write-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
								ERRIE
Access								W
Reset								–

Bit 0 – ERRIE Error Interrupt Enable

Value	Description
0	No effect.
1	The Multibit error interrupt is enabled. An interrupt will be raised if at least one error is detected in at least one sector.

16.19.16 PMECC Interrupt Disable Register

Name: HSMC_PMECCIDR
Offset: 0x090
Reset: –
Property: Write-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
								ERRID
Access								W
Reset								–

Bit 0 – ERRID Error Interrupt Disable

Value	Description
0	No effect.
1	Multibit error interrupt disabled.

16.19.17 PMECC Interrupt Mask Register

Name: HSMC_PMECCIMR
Offset: 0x094
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
								ERRIM
Access								R
Reset								0

Bit 0 – ERRIM Error Interrupt Mask

Value	Description
0	Multibit error disabled.
1	Multibit error enabled.

16.19.18 PMECC Interrupt Status Register

Name: HSMC_PMECCISR
Offset: 0x098
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
	ERRIS[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bits 7:0 – ERRIS[7:0] Error Interrupt Status Register
When set to one, bit i of the HSMC_PMECCISR indicates that sector i is corrupted.

16.19.19 PMECC Redundancy x Register

Name: HSMC_PMECCx
Offset: 0xB0 + x*0x04 [x=0..13]
Reset: 0x00000000
Property: Read-only

Note: The block of registers HSMC_PMECCx[x=0..13] is instanced 8 times in the user interface.

Bit	31	30	29	28	27	26	25	24
	ECC[31:24]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	ECC[23:16]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	ECC[15:8]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	ECC[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bits 31:0 – ECC[31:0] BCH Redundancy
This register contains the remainder of the division of the codeword by the generator polynomial.

16.19.20 PMECC Remainder x Register

Name:	HSMC_REMx
Offset:	0x02B0 + x*0x04 [x=0..15]
Reset:	0x00000000
Property:	Read-only

Note: The block of registers HSMC_REMx[x=0..15] is instanced 8 times in the user interface.

Bit	31	30	29	28	27	26	25	24
			REM2NP3[13:8]					
Access			R	R	R	R	R	R
Reset			0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	REM2NP3[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
			REM2NP1[13:8]					
Access			R	R	R	R	R	R
Reset			0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	REM2NP1[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bits 29:16 – REM2NP3[13:0] BCH Remainder 2 * N + 3
When sector size is set to 512 bytes, bit REM2NP3[29] is not used and read as zero.
If bit i of the REM2NP3 field is set to one, then the coefficient of the X^i is set to one; otherwise, the coefficient is zero.

Bits 13:0 – REM2NP1[13:0] BCH Remainder 2 * N + 1
When sector size is set to 512 bytes, bit REM2NP1[13] is not used and read as zero.
If bit i of the REM2NP1 field is set to one, then the coefficient of the X^i is set to one; otherwise, the coefficient is zero.

16.19.21 PMECC Error Location Configuration Register

Name: HSMC_ELCFG
Offset: 0x500
Reset: 0x00000000
Property: Read/Write

Access			R	R	R	R	R	R
Reset			0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
								DONE
Access								R
Reset								0

Bits 13:8 – ERR_CNT[5:0] Error Counter value
This field indicates the number of roots of the polynomial.

Bit 0 – DONE Computation Terminated Interrupt Status
When set to one, this indicates that the error location engine has completed the root finding algorithm.

16.19.30 PMECC Error Location SIGMA0 Register

Name: HSMC_SIGMA0
Offset: 0x528
Reset: 0x00000001
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 13:0 – SIGMAx[13:0] Coefficient of degree x in the SIGMA polynomial
SIGMAx belongs to the finite field GF(2^{13}) when the sector size is set to 512 bytes.
SIGMAx belongs to the finite field GF(2^{14}) when the sector size is set to 1024 bytes.

16.19.32 PMECC Error Location x Register

Name: HSMC_ERRLOCx
Offset: 0x05AC + x*0x04 [x=0..31]
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								
Bit	**23**	**22**	**21**	**20**	**19**	**18**	**17**	**16**
Access								
Reset								
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**
			ERRLOCN[13:8]					
Access			R	R	R	R	R	R
Reset			0	0	0	0	0	0
Bit	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	ERRLOCN[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bits 13:0 – ERRLOCN[13:0] Error Position within the Set {sector area, spare area}
ERRLOCN points to 1 when the first bit of the main area is corrupted.
If the sector size is set to 512 bytes, the ERRLOCN points to 4096 when the last bit of the sector area is corrupted.
If the sector size is set to 1024 bytes, the ERRLOCN points to 8192 when the last bit of the sector area is corrupted.
If the sector size is set to 512 bytes, the ERRLOCN points to 4097 when the first bit of the spare area is corrupted.
If the sector size is set to 1024 bytes, the ERRLOCN points to 8193 when the first bit of the spare area is corrupted.

16.19.33 Setup Register

Name: HSMC_SETUPx
Offset: 0x0700 + x*0x14 [x=0..3]
Reset: 0x01010101
Property: Write-only

This register can only be written if the WPEN bit is cleared in the Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
			NCS_RD_SETUP[5:0]					
Access			W	W	W	W	W	W
Reset			0	0	0	0	0	1

Reset			0	0	0	0	0	1

Bit	7	6	5	4	3	2	1	0
			NWE_SETUP[5:0]					
Access			W	W	W	W	W	W
Reset			0	0	0	0	0	1

Bits 29:24 – NCS_RD_SETUP[5:0] NCS Setup Length in Read Access
In Read access, the NCS signal setup length is defined as:
NCS setup length = (128 * NCS_RD_SETUP[5] + NCS_RD_SETUP[4:0]) clock cycles.

Bits 21:16 – NRD_SETUP[5:0] NRD Setup Length
The NRD signal setup length is defined as:
NRD setup length = (128 * NRD_SETUP[5] + NRD_SETUP[4:0]) clock cycles.

Bits 13:8 – NCS_WR_SETUP[5:0] NCS Setup Length in Write Access
In write access, the NCS signal setup length is defined as:
NCS setup length = (128 * NCS_WR_SETUP[5] + NCS_WR_SETUP[4:0]) clock cycles.

Bits 5:0 – NWE_SETUP[5:0] NWE Setup Length
The NWE signal setup length is defined as:
NWE setup length = (128 * NWE_SETUP[5] + NWE_SETUP[4:0]) clock cycles.

16.19.34 Pulse Register

Name: HSMC_PULSEx
Offset: 0x0704 + x*0x14 [x=0..3]
Reset: 0x01010101
Property: Write-only

This register can only be written if the WPEN bit is cleared in the Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
		NCS_RD_PULSE[6:0]						
Access		W	W	W	W	W	W	W

Bit	7	6	5	4	3	2	1	0
		NWE_PULSE[6:0]						
Access		W	W	W	W	W	W	W
Reset		0	0	0	0	0	0	1

Bits 30:24 – NCS_RD_PULSE[6:0] NCS Pulse Length in READ Access
In READ mode, The NCS signal pulse length is defined as:
NCS pulse length = (256 * NCS_RD_PULSE[6] + NCS_RD_PULSE[5:0]) clock cycles.

Bits 22:16 – NRD_PULSE[6:0] NRD Pulse Length
The NRD signal pulse length is defined as:
NRD pulse length = (256 * NRD_PULSE[6] + NRD_PULSE[5:0]) clock cycles.
The NRD pulse width must be as least 1 clock cycle.

Bits 14:8 – NCS_WR_PULSE[6:0] NCS Pulse Length in WRITE Access
In Write access, The NCS signal pulse length is defined as:
NCS pulse length = (256 * NCS_WR_PULSE[6] + NCS_WR_PULSE[5:0]) clock cycles.
The NCS pulse must be at least one clock cycle.

Bits 6:0 – NWE_PULSE[6:0] NWE Pulse Length
The NWE signal pulse length is defined as:
NWE pulse length = (256 * NWE_PULSE[6]+NWE_PULSE[5:0]) clock cycles.
The NWE pulse must be at least one clock cycle.

16.19.35 Cycle Register

Name: HSMC_CYCLEx
Offset: 0x0708 + x*0x14 [x=0..3]
Reset: 0x00030003
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
								NRD_CYCLE[8]
Access								R/W
Reset								0
Bit	23	22	21	20	19	18	17	16

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	1	1

Bits 24:16 – NRD_CYCLE[8:0] Total Read Cycle Length
The total read cycle length is the total duration in clock cycles of the read cycle. It is equal to the sum of the setup, pulse and hold steps of the NRD and NCS signals. It is defined as:
Read cycle length = (NRD_CYCLE[8:7] * 256) + NRD_CYCLE[6:0] clock cycles.

Bits 8:0 – NWE_CYCLE[8:0] Total Write Cycle Length
The total write cycle length is the total duration in clock cycles of the write cycle. It is equal to the sum of the setup, pulse and hold steps of the NWE and NCS signals. It is defined as:
Write cycle length = (NWE_CYCLE[8:7] * 256) + NWE_CYCLE[6:0] clock cycles.

16.19.36 Timings Register

Name: HSMC_TIMINGSx
Offset: 0x070C + x*0x14 [x=0..3]
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
	NFSEL				TWB[3:0]			
Access	R/W				R/W	R/W	R/W	R/W
Reset	0				0	0	0	0

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit 31 – NFSEL NAND Flash Selection
If this bit is set to one, the chip select is assigned to NAND Flash write enable and read enable lines drive the Error Correcting Code module.

Bits 27:24 – TWB[3:0] WEN High to REN to Busy
Write Enable rising edge to Ready/Busy falling edge timing.
Write Enable to Read/Busy = (TWB[3] * 64) + TWB[2:0] clock cycles.

Bits 19:16 – TRR[3:0] Ready to REN Low Delay
Ready/Busy signal to Read Enable falling edge timing.
Read to REN = (TRR[3] * 64) + TRR[2:0] clock cycles.

Bit 12 – OCMS Off Chip Memory Scrambling Enable
When set to one, the memory scrambling is activated. (Value must be zero if external memory is NAND Flash and NFC is used).

Bits 11:8 – TAR[3:0] ALE to REN Low Delay
Address Latch Enable falling edge to Read Enable falling edge timing.
Address Latch Enable to Read Enable = (TAR[3] * 64) + TAR[2:0] clock cycles.

Bits 7:4 – TADL[3:0] ALE to Data Start
Last address latch cycle to the first rising edge of WEN for data input.
Last address latch to first rising edge of WEN = (TADL[3] * 64) + TADL[2:0] clock cycles.

Bits 3:0 – TCLR[3:0] CLE to REN Low Delay
Command Latch Enable falling edge to Read Enable falling edge timing.
Latch Enable Falling to Read Enable Falling = (TCLR[3] * 64) + TCLR[2:0] clock cycles.

16.19.37 Mode Register

Name: HSMC_MODEx
Offset: 0x0710 + x*0x14 [x=0..3]
Reset: 0x00001003
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
				DBW				BAT
Access				R/W				R/W
Reset				1				0

Bit	7	6	5	4	3	2	1	0
			EXNW_MODE[1:0]				WRITE_MODE	READ_MODE
Access			R/W	R/W			R/W	R/W
Reset			0	0			1	1

Bit 12 – DBW Data Bus Width

Value	Name	Description
0	BIT_8	8-bit bus
1	BIT_16	16-bit bus

Bit 8 – BAT Byte Access Type
This field is used only if DBW defines a 16-bit data bus.

Value	Name	Description
0	BYTE_SELECT	Byte select access type: • Write operation is controlled using NCS, NWE, NBS0, NBS1. • Read operation is controlled using NCS, NRD, NBS0, NBS1.
1	BYTE_WRITE	Byte write access type: • Write operation is controlled using NCS, NWR0, NWR1. • Read operation is controlled using NCS and NRD.

Bits 5:4 – EXNW_MODE[1:0] NWAIT Mode
The NWAIT signal is used to extend the current read or write signal. It is only taken into account during the pulse phase Read and Write controlling signal. When the use of NWAIT is enabled, at least one cycle hold duration must be programmed for the read and write controlling signal.

Value	Name	Description
0	DISABLED	Disabled—The NWAIT input signal is ignored on the corresponding Chip Select.
1	–	Reserved
2	FROZEN	Frozen Mode—If asserted, the NWAIT signal freezes the current read or write cycle. After deassertion, the read/write cycle is resumed from the point where it was stopped.
3	READY	Ready Mode—The NWAIT signal indicates the availability of the external device at the end of the pulse of the controlling read or write signal, to complete the access. If high, the access normally completes. If low, the access is extended until NWAIT returns high.

Bit 1 – WRITE_MODE Selection of the Control Signal for Write Operation

Value	Name	Description
0	NCS_CTRL	The Write operation is controller by the NCS signal.
1	NWE_CTRL	The Write operation is controlled by the NWE signal

Bit 0 – READ_MODE Selection of the Control Signal for Read Operation

Value	Name	Description
0	NCS_CTRL	The Read operation is controlled by the NCS signal.
1	NRD_CTRL	The Read operation is controlled by the NRD signal.

16.19.38 Off Chip Memory Scrambling Register

Name: HSMC_OCMS
Offset: 0x7A0
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16

Access								
Reset								

Bit	7	6	5	4	3	2	1	0
							SRSE	SMSE
Access							R/W	R/W
Reset							0	0

Bit 1 – SRSE NFC Internal SRAM Scrambling Enable

Value	Description
0	Disable Scrambling for NFC internal SRAM access.
1	Enable Scrambling for NFC internal SRAM access. (OCMS bit must be cleared in the corresponding HSMC_TIMINGSx register.)

Bit 0 – SMSE Static Memory Controller Scrambling Enable

Value	Description
0	Disable “Off Chip” Scrambling for SMC access.
1	Enable “Off Chip” Scrambling for SMC access. (If OCMS bit is set in the corresponding HSMC_TIMINGSx register.)

16.19.39 Off Chip Memory Scrambling Key1 Register

Name: HSMC_KEY1
Offset: 0x7A4
Reset: 0x00000000
Property: Write-once

Bits 31:0 – KEY2[31:0] Off Chip Memory Scrambling (OCMS) Key Part 2
When Off Chip Memory Scrambling is enabled by setting the HSMC_OCMS and HSMC_TIMINGS registers in accordance, the data scrambling depends on KEY2 and KEY1 values.

16.19.41 Clock Configuration Register

Name: HSMC_CLKCFG
Offset: 0x7AC
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								
Bit	23	22	21	20	19	18	17	16
							CLKEDGE	CLKEN
Access							R/W	R/W
Reset							0	0
Bit	15	14	13	12	11	10	9	8
								CLKDIV[8]
Access								R/W
Reset								0
Bit	7	6	5	4	3	2	1	0
	CLKDIV[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit 17 – CLKEDGE SMC Clock Edge

Value	Description
0	The start of the external bus access is aligned with the rising edge of the SMC clock output.
1	The start of the external bus access is aligned with the falling edge of the SMC clock output.

Bit 16 – CLKEN SMC Clock Enable

Value	Description
0	The SMC clock is disabled.
1	The SMC clock is enabled.

Bits 8:0 – CLKDIV[8:0] SMC Clock Divider
The SMC clock output frequency is equal to periph_clk/(CLKDIV + 1). If CLKDIV = 0, the SMC clock output frequency is equal to periph_clk/2.

16.19.42 Write Protection Mode Register

Name: HSMC_WPMR
Offset: 0x7E4
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
	WPKEY[23:16]							
Access	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	WPKEY[15:8]							
Access	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	WPKEY[7:0]							
Access	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
								WPEN
Access								R/W
Reset								0

Bits 31:8 – WPKEY[23:0] Write Protection Key

Value	Name	Description
0x534D43	PASSWD	Writing any other value in this field aborts the write operation of bit WPEN. Always reads as 0.

Bit 0 – WPEN Write Protection Enable
See Register Write Protection for list of write-protected registers.

Value	Description
0	Disables write protection if WPKEY value corresponds to 0x534D43 (“SMC” in ASCII)
1	Enables write protection if WPKEY value corresponds to 0x534D43 (“SMC” in ASCII)

16.19.43 Write Protection Status Register

Name: HSMC_WPSR
Offset: 0x7E8
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								
Bit	**23**	**22**	**21**	**20**	**19**	**18**	**17**	**16**
	WPVSRC[15:8]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**
	WPVSRC[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0
Bit	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
								WPVS
Access								R
Reset								0

Bits 23:8 – WPVSRC[15:0] Write Protection Violation Source
When WPVS = 1, WPVSRC indicates the register address offset at which a write access has been attempted.

Bit 0 – WPVS Write Protection Violation Status

Value	Description
0	No write protect violation has occurred since the last read of the HSMC_WPSR.
1	A write protect violation has occurred since the last read of the HSMC_WPSR. If this violation is an unauthorized attempt to write a protected register, the associated violation is reported into field WPVSRC.

17. Universal DDR Memory Controller (UDDRC)

17.1 Description

The SDRAM memory interface is made of:

- the Universal DDR Memory Controller (UDDRC) and
- the PHYsical layer interface (DDR3PHY).

The UDDRC receives transactions from the internal buses. These transactions are queued internally and scheduled for access in order to the DDR-SDRAM while satisfying the DDR-SDRAM protocol timing requirements, transaction priorities, and dependencies between transactions.

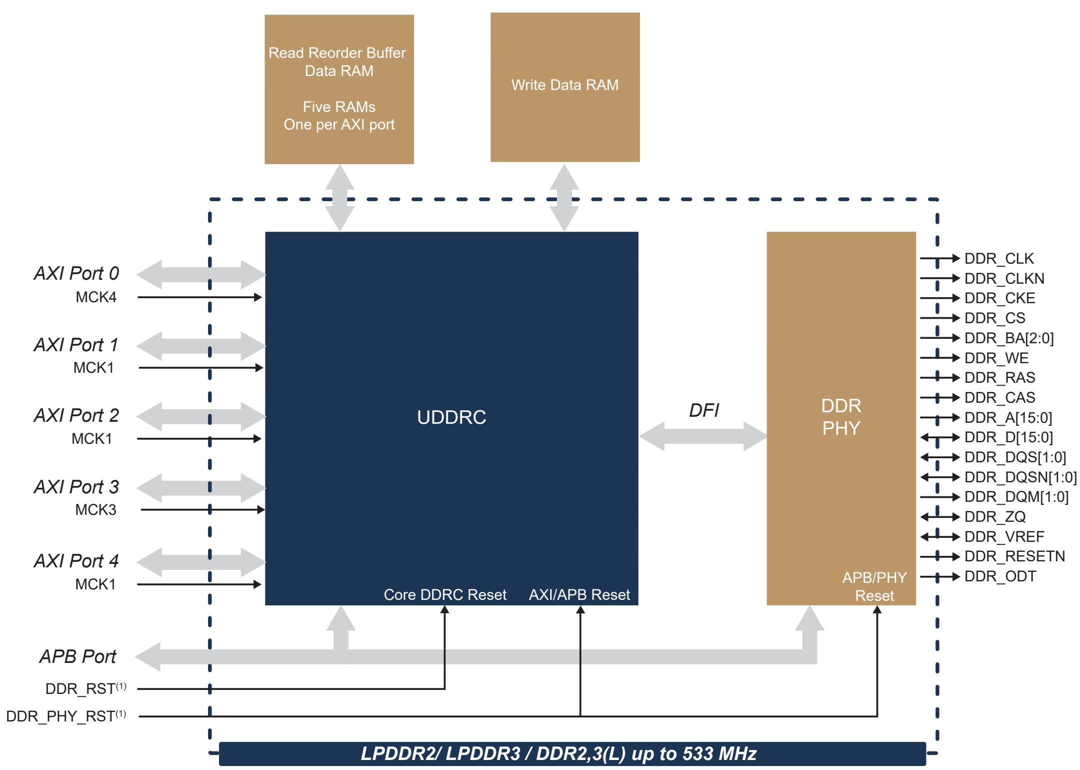
17.2 Embedded Characteristics

- Interface to DDR2, DDR3, LPDDR2, LPDDR3 Memories
- All Signals Supported on Control, Write Data and Read Data Interfaces
- Internal 5 AXI Ports Controller with Arbitration
- External 16-bit DDR Interface
- Support for 1 Memory Rank
- For DDR3, LPDDR2 and LPDDR3 Configurations: Direct Software Request Control or Programmable Internal Control for ZQ Short Calibration Cycles
- For DDR3, LPDDR2 and LPDDR3 Configurations: Support for ZQ Long Calibration after Self-refresh Exit
- For LPDDR2 and LPDDR3 Configurations: Support for ZQ Reset Feature through Software
- Dynamic Scheduling to Optimize Bandwidth and Latency
- Read and Write Buffers in Fully Associative CAMs (Content Addressable Memories)
- Delayed Writes for Optimum Performance on SDRAM Data Bus
- Software-programmable Quality of Service (QoS) Support
- Control Options to Avoid Starvation of Lower Priorities
- Coherency for Write-After-Read (WAR) and Read-After-Write (RAW) Hazards
- Paging Policy Selectable by Configuration Registers:
  - Leave pages open after accesses, or
  - Close page when no further accesses are available in the controller for that page, or
  - Auto-precharge with each access, with an optimization for Page Close mode which leaves the page open after a flush for read-write and write-read collision cases
- Supports Automatic DDR-SDRAM Power-down Entry and Exit caused by Lack of Incoming Transaction for a Programmable Time
- Supports Automatic Clock Stop (LPDDR2/LPDDR3) Entry and Exit caused by Lack of Incoming Transaction
- Supports Automatic UDDRC Low-power Mode Operation caused by Lack of Transaction Arrival for a Programmable Time through the Hardware Low-power Interface
- Supports Self-refresh Entry and Exit as follows:
  - Support for automatic self-refresh entry and exit caused by lack of incoming transaction for a programmable time
  - Support for self-refresh entry and exit under software control
  - Support for self-refresh entry and exit using dedicated DDRC hardware low-power interface control
- Support for Dynamically Changing Clock Frequency while in Self-refresh:
  - DDR3 DLL-off mode supported
  - Shadow timing registers provided to allow fast frequency changing
- Support for Deep Power-down Entry and Exit under Software Control (LPDDR2/LPDDR3)
- Support for explicit SDRAM Mode Register Updates under Software Control
- Flexible Address Mapper Logic to allow Application-specific Mapping of Row, Column, Bank, and Rank Bits

- Programmable Support for 1T or 2T Timing
- User-selectable Refresh Control Options:
  – Controller-generated auto-refreshes at programmable average intervals
  – Ability to disable controller-generated auto-refreshes
  – Ability to issue a refresh through direct software request
  – When LPDDR2/LPDDR3 is used, user-selectable ability to perform per-bank refreshes rather than all-banks refreshes
- Advanced Power-saving Design Includes No Unnecessary Toggling of Command, Address, and Data Pins (RAS/CAS/WE/BA/A hold last state after each command; DDR_D does not transition on writes when bytes are disabled)
- Support for DDR2, DDR3, DDR3L, LPDDR2, LPDDR3
- Leverages Out-of-order Requests to Maximize Throughout
- The UDDRC Implements the Following Standards:
  – JEDEC DDR2 SDRAM Specification, JESD79-2
  – JEDEC DDR3 SDRAM Specification, JESD79-3
  – JEDEC LPDDR2 SDRAM Specification, JESD209-2
  – JEDEC LPDDR3 SDRAM Specification, JESD209-3

17.3 Block Diagram

Figure 17-1. UDDRC Block Diagram



(1) DDR_RST and DDR_PHY_RST are driven by the reset controller. Refer to the “Reset Controller (RSTC)” section for more details.

17.4 I/O Lines Description

Table 17-1. DDR/LPDDR I/O Lines Description

Name	Function	Type	Active Level
DDR/LPDDR Controller			
VDDIODDR	Power Supply of memory interface	Power	–

DDR_A7	CA7
DDR_A8	CA8
DDR_A9	CA9
Higher addresses	Higher CAs

17.5 Functional Description

The UDDRC converts system bus transactions into memory commands that are compliant with the DDR protocols.

The UDDRC performs the following functions:

- Accepts requests from the SoC core with system addresses and associated data for writes.
- Performs address mapping from system addresses to SDRAM addresses (rank, bank, bank group, row).
- Prioritizes requests to minimize the latency of reads (especially high priority reads) and maximize page hits.
- Ensures that the SDRAM is properly initialized.
- Ensures that all requests made to the SDRAM are legal (accounting for associated SDRAM constraints)
- Ensures that refreshes and other SDRAM maintenance requests are inserted as required.
- Controls when the SDRAM enters and exits the various power-saving modes appropriately.

17.5.1 AXI Port Interface (XPI)

The AXI protocol is burst-based with read and write request channels that specify the host ID for the request, start byte address, burst length, burst size, and burst type. This information is processed by the interface and is used subsequently by the UDDRC.

The XPI interfaces the AXI application port to the UDDRC and performs the following main functions:

- Read address generation
- Write address generation
- Write data generation
- Read data and response generation

- Write response generation

The XPI converts AXI bursts into read and write requests, which are forwarded to the Port Arbiter (PA). In the opposite direction, the XPI converts the responses from the DDRC into appropriate AXI responses.

The AXI Specification requires that transactions must not cross a 4K address boundary.

17.5.1.1 Read Address Channel

The AXI read address channel has the following features:

- The read transaction can be of any length up to 256 for incremental bursts, 16 for wrapping bursts.
- The burst types supported are incremental and wrapping.
- The burst start address can be unaligned to the AXI data width boundaries.
- The size of the burst can be less than the full width of the AXI data bus (also known as subsized transfers).

The signals on the read address channel are registered into the XPI in accordance with the AXI valid/read handshaking protocol and are synchronous with the AXI clock (aclk).

Read requests are accepted if the request can be written into the Read Address Queue (RAQ). This is used to store all the read address requests. There is a single address queue on a given port.

Each AXI port can store in its RAQ up to:

- Port 0: 8 addresses
- Port 1: 2 addresses
- Port 2: 16 addresses
- Port 3: 2 addresses
- Port 4: 16 addresses

17.5.1.2 Write Address Channel

Write Address Queue (WAQ) is used to store all the addresses for write requests from a given port. There is a single queue for all AXI IDs from a given port. The write address channel behavior is similar to the read address channel.

Each AXI port can stored in its WAQ up to:

- Port 0: 8 addresses
- Port 1: 2 addresses
- Port 2: 8 addresses
- Port 3: 4 addresses
- Port 4: 16 addresses

Write address and read address channels are independent and the ordering between the write and read requests may not be preserved.

To preserve the sequence, a higher-level protocol needs to wait for read/write response before sending the next transaction.

Transactions across the ports are independent and can be issued in any order.

17.5.1.3 Wrap Burst Expansion

A WRAP burst may be expanded by the XPI into multiple SDRAM transactions. This is also true for cases where WRAP bursts, which could be accommodated by a single transaction on the SDRAM interface.

17.5.1.4 Software Coherency for AXI Ports

The Address Collision Handling section describes how the DDRC handles in-order execution of commands to the same address.

For the commands issued at the AXI port, the logic in the DDRC protects against all types of software coherency hazards when the AXI host waits for write (read) response before sending the next same address read (same address write) or vice-versa.

17.5.2 Port Arbiter (PA)

The Port Arbiter block arbitrates command requests from the AXI ports to the HIF of the DDR Controller (DDRC). PA is comprised of multiple tiers of arbitration stages which include:

- Read/write arbitration
- 2-priority level arbitration based on port aging and expired-VPR/expired-VPW commands (timeout-priority0)
- 2-priority level arbitration for read requests based on DDRC read priorities
- 32-priority level arbitration based on internal port aging or 16-priority level arbitration based external AXI QoS inputs
- Round-robin arbitration to resolve ports having the same priority after passing all stages of arbitration

17.5.2.1 Registers Related to Port Arbiter

The following are the registers related to the Port Arbiter:

- UDDRC_SCHED
- UDDRC_SCHED1
- UDDRC_SCHED2

For more information about these registers, see Register Descriptions.

17.5.3 Address Mapper

Read and write requests are provided to the UDDRC with a system address. The system address is the command address of a transaction as presented on one of the data ports. The UDDRC converts this system address to a physical address. It maps the system address to the SDRAM rank, bank, row, and column addresses.

The first part of the mapping is conversion of system address to AXI byte address. The controller maps disjoint address regions to internal consecutive addresses. Otherwise, the controller assumes that the DRAM is always mapped as a monolithic block. For more information about this, see System Address Regions.

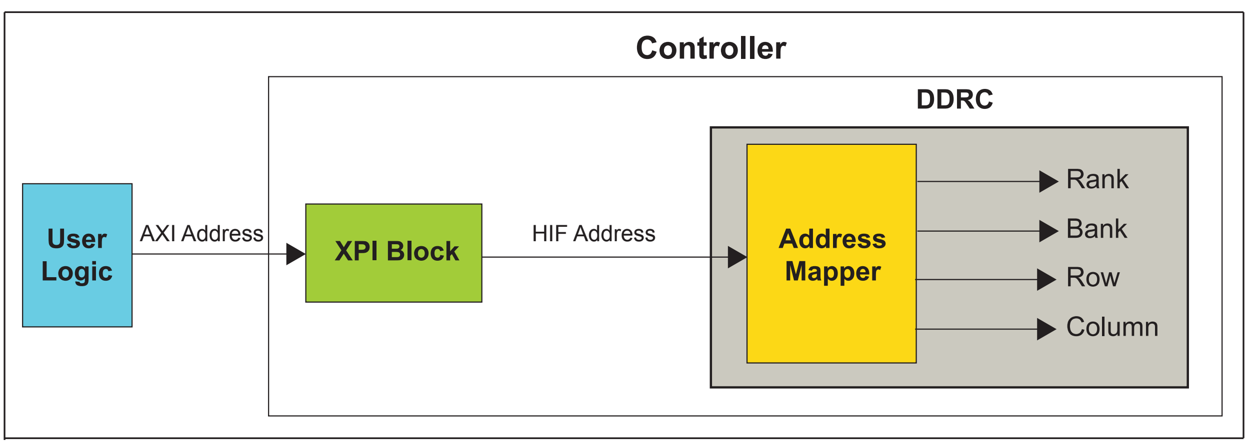
The second part of this mapping is the conversion of AXI byte address to HIF word address. This is performed in the XPI block, and is applicable to AXI configurations only. For more information about this, see Application to HIF Address Mapping.

The last part is the conversion of HIF word address to SDRAM address. A flexible address mapper maps the HIF word address to the SDRAM rank/bank/bank group/row/column address. This address mapper is located within the DDRC.

The address mapping to be used depends on the use-case. The UDDRC provides a set of registers that allows flexible re-programming of logical to physical address mapping. For more information about this, see HIF Address to SDRAM Address Mapping.

The following figure explains the conversion of AXI to HIF to the SDRAM rank/bank/row/column/bank group addresses.

Figure 17-2. Conversion of AXI to HIF to SDRAM Rank/Bank/Row/Column/Bank Group Addresses



17.5.3.1 System Address Regions

The system address regions add the capability to define up to four disjoint memory regions mapping to the DRAM as consecutive addresses.

Each region is defined by:

- Base Address: starting address of the region aligned to the minimum block size.
- Number of Blocks: size of the region in multiples of minimum block size.

The base address of each region is specified by the register SARBASEn.base_addr and the total number of blocks is specified by the register SARSIZEn.nblocks (see Register Descriptions).

System address region specification is the same for all ports. Error response is not generated by the controller for addresses falling outside the specified address regions and the same address translation is applied from one base address to the next base address.

The base addresses must be specified such that they are in the ascending order (SARBASE0 < SARBASE1 < SARBASE2 < SARBASE3) and such that regions do not overlap.

17.5.3.2 Application to HIF Address Mapping

The {ARADDR | AWADDR} is a byte address. XPI maps the MSB bits of the application address to the HIF address (hif_cmd_addr) in the following ways:

- hif_cmd_addr [36:3] = {ARADDR | AWADDR} [31:4]
- hif_cmd_addr[2] is internally generated by XPI
- hif_cmd_addr [1:0] = 0

17.5.3.3 HIF Address to SDRAM Address Mapping

The address mapper maps HIF word addresses to SDRAM addresses by selecting the HIF address bit that maps to each and every applicable SDRAM address bit. While it is possible to map HIF address bits to an SDRAM address in any desired manner, the full available address space is accessible only when no two SDRAM address bits are determined by the same HIF address bit. Each SDRAM address bit has an associated register vector to determine its source.

Registers ADDRMAPx (x = 0 to 11) are used to program the address mapper. For more information on ADDRMAP registers, see Register Descriptions.

The HIF address bit number is determined by adding the internal base of the ADDRMAPx (x = 0 to 11) register to the programmed value for that register, as described in the following equation:

HIF address bit number = [internal base] + [register value]

For example, for ADDRMAP3.addrmap_col_b7, the internal base is 7. When full data bus is in use, column bit 7 is determined by the following equation:

7 + [register value]

If this register is programmed to 2, the HIF address bit can be calculated by using following equation:

[HIF address bit number] = 7 + 2 = 9

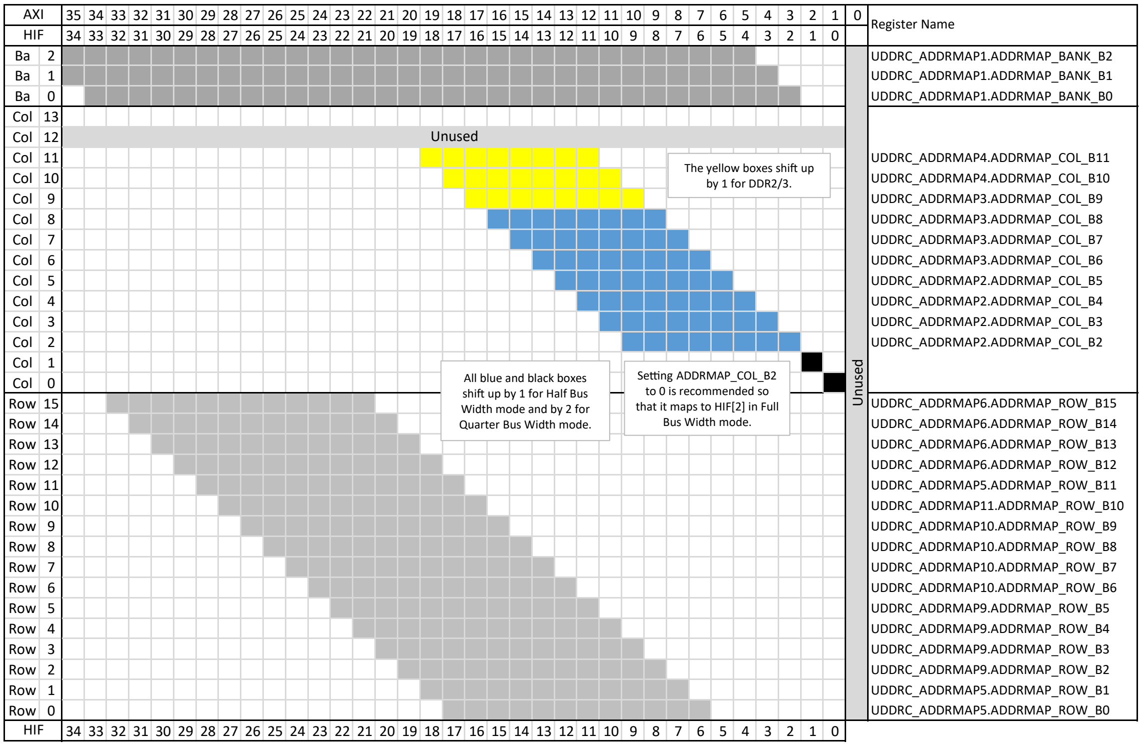
In other words, the column address bit 7 sent to SDRAM would always be equal to hif_cmd_addr[9] of the corresponding HIF source address.

Notes:

1. All of the column bits shift up 1 bit when only half of the data bus is in use. In this case, you need to look at ADDRMAP3.addrmap_col_b6 instead to determine the value of column address bit 7.
2. All of the column bits shift up 2 bits when only a quarter of the data bus is in use. In this case, you need to look at ADDRMAP2.addrmap_col_b5 instead to determine the value of column address bit 7.
3. The addressing for column bits is independent of hardware configuration. The column bits do not shift up by an additional 1 bit.
4. The register ADDRMAP5.addrmap_row_b2_10 can map multiple HIF address bits (if the value set is lesser than 15). If set to 15, then ADDRMAP9, ADDRMAP10, and ADDRMAP11 registers are used, which provide individual mapping for the HIF address bits (rows 2 to 10).
5. For any address bits which cannot be in use in all cases, all bits of the associated address map register must be set to 1 when the associated SDRAM address bit is not in use.

The system address to physical address mapping can be done by choosing any one of the possible combinations from the following figure. It explains the different possible ways to map the HIF address bits to the SDRAM rank/bank/bank group/row/column address.

Figure 17-3. System Address to Physical Address Mapping



17.5.3.4 Registers Related to Address Mapper

The following are the registers related to the Address Mapper:

- UDDRC_ADDRMAP1
- UDDRC_ADDRMAP2
- UDDRC_ADDRMAP3
- UDDRC_ADDRMAP4
- UDDRC_ADDRMAP5
- UDDRC_ADDRMAP6
- UDDRC_ADDRMAP9
- UDDRC_ADDRMAP10
- UDDRC_ADDRMAP11

For more information about these registers, see Register Descriptions.

17.5.4 Address Collision Handling

The UDDRC can execute transactions out-of-order while ensuring that all transactions appear as if they are executed in the order in which they are received. Every transaction that requires a response from the UDDRC arrives with a token number which is provided back to the SoC core as part of the response. Since the UDDRC queues transactions prior to execution, it is possible that multiple transactions to the same SDRAM address arrive before the first transaction to that address is issued.

For address collision, two HIF addresses are considered the same address if all of the HIF address bits (except for the LSB column values) are the same. That is, the "collision" ignores the LSB column values when comparing addresses. The following HIF address bits are ignored during comparison:

- HIF[2+addrmap_col_b2]
- HIF[1:0]

17.5.5 Quality of Service (QoS)

Quality of Service is extremely important in distributing the available resources (bandwidth or latency) amongst the different devices in a fair mechanism to meet the overall performance requirements.

In the circuit, there are multiple hosts trying to communicate with different clients through Interconnect. Interconnect is used to route the traffic between the hosts and clients. There are potential chances of bandwidth sensitive host starving for data and latency sensitive host requirements are not met. This impacts the overall performance of the subsystem. QoS addresses these kinds of performance issues in subsystem.

17.5.5.1 Traffic Classes

The UDDRC supports different traffic classes that are distinguished from each other by the internal ‘arqos’ signal.

17.5.5.1.1 Read Classes

- Low Priority Read (LPR): also called “the best effort traffic”. There is no resource allocation and it shares the resources with the other traffic types. LPR is always treated as low priority in the PA and in the DDRC. There are timeout mechanisms that can be used to prevent starvation for both the PA and the DDRC. When there is a timeout in the PA, that port becomes the highest priority (priority0). When there is a timeout in the LPR store in the DDRC (in other words, LPR store becomes critical), the LPR entries are served before HPR entries.
- Variable Priority Read (VPR): also called “the maximum latency bound traffic” for meeting real time deadlines in video or audio applications. VPR traffic shares the same resources with LPR in the DDRC. But, based on the configuration, it may have a dedicated queue (red or blue) in the XPI. It has the same priority as LPR, but lower priority than HPR for the PA. For the DDRC, VPR has the same initial priority as LPR. Each command tagged as VPR has an associated latency timer. When expired, VPR transactions have the highest priority in the controller, both in the PA and in the DDRC. The purpose of this traffic class is to limit the maximum latency, where this latency bound is expected to be a few hundred clock cycles.
- High Priority Read (HPR): it has allocated resources. If the XPIs are configured to have dual read address queues, then the red queue can be allocated to HPR. For DDRC, HPR traffic goes to its own dedicated store. HPR traffic has higher priority than LPR. HPR is meant for latency critical but not real time applications such as CPU.

17.5.5.1.2 Write Classes

- Normal Priority Write (NPW): it is also called as the best effort traffic. There is no resource allocation and it shares the resources with the other traffic types. It is always treated as normal priority in the PA and DDRC. There are timeout mechanisms that can be used to prevent starvation for the PA. When there is a timeout in the PA, that port becomes the highest priority (priority0).
- Variable Priority Write (VPW): it is also called as the maximum latency bound traffic to meet real time deadlines in video or audio applications. VPW traffic shares the same resources with NPW in the DDRC. For the DDRC, VPW has the same initial priority as NPW. Each command tagged as VPW has an associated latency timer. When expired, VPW transactions have the highest priority in the controller, both in the PA and in the DDRC. The purpose of this traffic class is to limit the maximum latency, where this latency bound is expected to be a few hundred clock cycles.

17.5.5.1.3 QoS Mapping

The priority of an initiator (host) is susceptible to change by the intermediate agents (for example, interconnect) before reaching the destination client depending on the service levels provided with respect to the required targets. Therefore, the relationship between the IDs and their class representations must be dynamically determined.

Arqos/awqos internal signal determines both port priorities and DDRC priorities dynamically. 16 QoS levels are divided to three regions for reads, two regions for writes. Each region can be assigned to any of the following traffic class—LPR, VPR, and HPR for reads, NPW and VPW for writes.

Regions 0 and 1 are assigned to the blue address queue (see Dual Read Address Queue). Typically, LPR/NPW and VPR/VPW may share this resource.

Region 2 is assigned to the red queue (see Dual Read Address Queue) for reads (when dual queue is selected), while for writes it is assigned to the same queue as Region 0 and Region 1 (being writes, always single queue). Region 2 can be mapped to HPR or VPR traffic for reads, VPW or NPW traffic for writes. In the DDRC, LPR/NPW and VPR/VPW share the same CAM store called LPR/NPW store. HPR has its own store in the DDRC.

The regions are mapped per port using PCFGQOS0_n and PCFGWQOS0_n registers (see Register Descriptions).

Fields for PCFGQOS0_n register are as follows:

- rqos_map_level<x> (where x is 1 to 2) indicates two separation levels for three regions. Possible values 0 to 14 correspond to an arqos value. These registers indicate the upper end of the region. For example, if rqos_map_level2 is set to 14, then Region 2 is identified as all transactions with arqos value of 15.
- rqos_map_region<y> (where y is 0 to 2) for region identifier. This register indicates the traffic class of each of the three regions. rqos_map_region2 is present only in dual read queue configurations (see Dual Read Address Queue).
  Valid values are:
  - 0–LPR
  - 1–VPR
  - 2–HPR

For single address queue configurations, Region 0 and Region 1 map to the blue queue. Being single queue, Region 2 is not present. In this case registers rqos_map_level2 and rqos_map_region2 do not exist. In this case Region 0 can be set to HPR or VPR, Region 1 to VPR or LPR.Fields for PCFGWQOS0_n register are as follows:

- wqos_map_level<x> (where x is 1 to 2) indicates the separation level for three regions Possible values 0 to 14 correspond to an awqos value. These registers indicate the upper end of the region. For example, if wqos_map_level2 is set to 14, then Region 2 is identified as all transactions with awqos value of 15.
- wqos_map_region<y> (where y is 0 to 2) for region identifier. This register indicates the traffic class of each of the two regions.

Valid values are:

- 0–NPW
- 1–VPW

Writes are always single queue: Region 0, Region 1 and Region 2 map all to the same queue. All fields always exist.

17.5.5.1.4 Dual Read Address Queue

In this circuit, the function is enabled for port 2, not for ports 0, 1, 3, 4.

When enabled, there are two separate read address queues in the XPI block—red queue and blue queue.

Both read queues request independently to the PA.

Red queue can be used for one traffic class only and associated to Region 2 in the QoS mapper (HPR or VPR).

Blue queue can be used for two traffic classes and associated to Region 0 and Region 1 in the QoS mapper (VPR and/or LPR).

There are separate time-outs for the blue and red queues. Timers are started to down count when the transaction is accepted in the XPI, which are then forwarded to DDRC together with the command.

17.5.5.1.5 ID Collisions

Due to the dynamic nature of the QoS with respect to the IDs, two transactions of the same ID can potentially exist in two queues. The collisions can be classified as:

- Blue after Red (BAR): a command with ID x is presented to the blue queue where a command with the same ID x is outstanding in the red queue.
- Red after Blue (RAB): a command with ID x is presented to the red queue where a command with same ID x is outstanding in the blue queue.

In the XPI, for both collision types, the ordering consistency within a given ID is preserved by stalling the incoming transaction to be pushed into the address queue it is mapped to until the colliding transaction in the opposite queue exists. This is required for functional correctness.

In case of any ID collision, the UDDRC does not speed up the drain of the stored transactions in the address queue causing collision even if the incoming transaction is HPR. In other words, address queues request arbitration to the Port Arbiter with their normal mapped priorities.

17.5.5.2 VPR/VPW Timeout

There are separate timeouts for the blue and red queues for read transactions, and one timeout for write transactions. Timers are started to down count when the transaction is accepted in the XPI, which are then forwarded to DDRC together with the command.

Timeouts are set per port and queue using PCFGQOS1_n and PCFGWQOS1_n registers (see UDDRC_PCFGQOS1_0 and UDDRC_PCFGWQOS1_0).

For PCFGQOS1_n register:

- RQOS_MAP_TIMEOUTB: specifies the timeout value for transactions mapped to the blue queue.
- RQOS_MAP_TIMEOUTR: specifies the timeout value for transactions mapped to the red queue.

For PCFGWQOS1_n register:

- WQOS_MAP_TIMEOUT: specifies the timeout value for write transactions.

When expired, VPR/VPW transactions from XPI are tagged as expired-VPR or expired-VPW instead of LPR/NPW during normal priority transaction flow. The Port Arbiter treats these transactions with the highest priority (priority0). In addition, the Port Arbiter asserts hif_go2critical_lpr signal to the DDRC if there are no LPR credits available (LPR store of the read CAM is full) when an expired-VPR port is pending, and hif_go2critical_wr signal to the DDRC if there are no write credits available when an expired-VPW is pending. If an expired-VPW is issued as RMW at the HIF interface, the Port Arbiter asserts hif_go2critical_lpr signal to the DDRC if there are no LPR credits hif_go2critical_lpr and hif_go2critical_wr are asserted at the same time, priority in the DDRC is given to the read.

If VPR/VPW timeout registers are set to 0, the VPR/VPW transactions expire immediately as they enter the DDRMC, thereby making them the highest priority transaction class within the device. If multiple VPR/VPW transactions expire at the same time in the XPI, they are executed by the PA in round-robin order.

17.5.5.3 Registers Related to QoS

The following are the registers related to the QoS:

- UDDRC_PCFGQOS0_x
- UDDRC_PCFGQOS1_x
- UDDRC_PCFGWQOS0_x
- UDDRC_PCFGWQOS1_x

Five AXI ports are available, so x can vary from 0 to 4. For more information about these registers, see Register Descriptions.

17.5.6 Bypass Operation

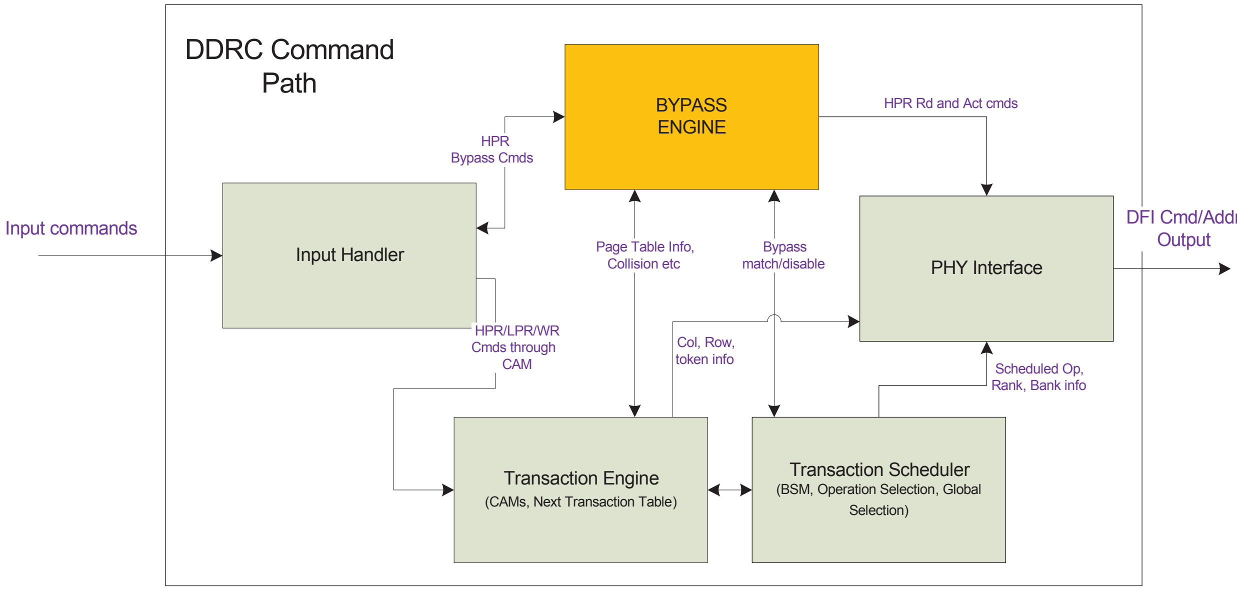
The bypass engine in the UDDRC handles high-priority, low-latency read requests.

The UDDRC supports two priority levels for read commands – high priority reads (HPR) and low priority reads (LPR). The Read CAM can be split into low and high priority sections using the SCHED.lpr_num_entries register. Generally, all the read commands of the controller are stored in the Read CAM. HPR commands are directed to the HP section and LPR commands directed to the LP section. The commands are then scheduled based on several factors such as priority, page match, and oldest entry. The HPR commands in the CAM are given higher priority over the LPR commands by the scheduling engine. However, the HPR commands can be present in the CAM for longer duration due to several factors.

If the bypass operation is enabled, the HPR commands can bypass the CAM and go directly to the PHY interface engine, thereby saving several clocks in latency.

The bypass and the CAM paths are shown in the following figure.

Figure 17-4. Bypass and CAM Paths



There are two types of bypass operations:

- Activate Bypass operation: if a HP Read command comes to a closed page, then the Activate request for this command is sent through the Bypass path. The command is still sent to the CAM and the Read part of this request happens through the CAM scheduling logic.
- Read Bypass operation: if a HP Read command comes to a page that is already open, then the Activate request is not necessary for this command. The Read is sent through the Bypass path.

Even if the input command satisfies the above mentioned conditions for the bypass operation, the command may not go through the Bypass path.

There are several reasons for this:

- The Controller is in Write mode.
- The Controller is performing critical maintenance commands such as Refresh, ZQ Calibration, MRW/MRR, and Critical Pre-charge.
- The Controller is handling a collision scenario.
- The Controller is performing a DFI Control Update request.

The idle latency through the DDRC for an Activate or a Read command going through the CAM path is 4 cycles. The idle latency when the same command goes through the Bypass path is 2 cycles.

17.5.6.1 Enabling Bypass Operation

To enable the bypass operation, DBG0.disable_act_bypass and DBG0.disable_rd_bypass registers should be 0 (see Register Descriptions).

17.5.6.2 Registers Related to Bypass Operation

The following are the registers related to the Bypass Operation:

- UDDRC_DBG0.DISABLE_ACT_BYPASS
- UDDRC_DBG0.DISABLE_RD_BYPASS

For more information about these registers, see Register Descriptions.

17.5.7 Burst Mode Operation

An abnormal read or write transaction on the host interface contains enough data for one DDR BL8 transaction in Full Bus Width mode. The actual burst length used on the DFI interface is controlled by MSTR.burst_rdwr[3:0] and the data bus width (MSTR.data_bus_width). When the PI (PHY interface block before DFI) splits read/write commands, it sends them back-to-back (or as close as is allowed by the protocol). This means that no other reads/writes/activates/

precharges can be sent to that bank, and no refreshes can be sent to that rank, between these commands. However, it is possible for a refresh to be sent to another rank at this time.

17.5.8 Refresh Controls

Refresh can be issued using the auto-refresh feature in the UDDRC or using the direct software request of the refresh command. The RFSHCTL3.dis_auto_refresh register bit selects the refresh method (see Register Descriptions). When this bit is set to 1, UDDRC uses direct software request of refresh command. When it is set to 0, the internal auto-refresh feature is used.

The purpose of refresh control is to:

- Reduce the bandwidth impact of refresh cycles
- Increase the likelihood of refreshes being serviced during idle periods
- Provide fine-gain control of the trading-off the above benefits (to gather refreshes) versus the increased worst case latencies associated with gathering refreshes

17.5.8.1 Refresh Using Direct Software Request of Refresh Command

Follow these steps to put the UDDRC in direct software request of Refresh Command mode:

1. Set the RFSHCTL3.dis_auto_refresh bit to 1. When the register bit is set, the UDDRC checks for any pending refreshes. Any pending refreshes are issued right away using the ‘critical refresh’ feature inside the UDDRC. After these refreshes are issued, all the refresh timers inside the UDDRC are reset to 0. They are re-activated only when the auto-refresh feature is enabled.
2. The SoC core must keep track of the refresh requirements of the SDRAM.
3. The refresh command can be issued by setting the register bits DBGCMD.rank*_refresh to 1 (see Register Descriptions). When the rank*_refresh request is stored in the UDDRC, the corresponding register bit is automatically cleared. The SoC core can initiate a rank*_refresh operation only if DBGSTAT.rank*_refresh_busy is low. The UDDRC issues refresh to the SDRAM at the earliest.
4. Software-driven refresh commands for each rank are loaded into a 9-entry buffer, and are issued by the UDDRC on the DFI as soon as it is legal to do so (the UDDRC controller must wait $t_{RFC(min)}$ between each refresh request). If the buffer saturates, the DBGSTAT.rank*_refresh_busy remains asserted to prevent software from initiating further refreshes.

17.5.8.2 Refresh Using Auto Refresh Feature Inside the UDDRC

The UDDRC provides advanced refresh controls. Besides fully-configurable refresh constraints ($t_{RFC(min)}$ and t_{REFI}), the UDDRC can also be programmed to gather refreshes to each rank of SDRAM to reduce the bandwidth consumed by refreshes and to increase the likelihood that refreshes can be serviced during an idle period.

Fine-grain control of the refreshes ensures these benefits can be balanced against worst case latencies associated with servicing refreshes together. Staggered refresh timers for multi-rank configurations of the UDDRC allow transactions to continue to other ranks while refreshes are taking place to just one rank.

To minimize the worst case impact of a forced refresh cycle, the UDDRC can be programmed to issue single refreshes at a time by forcing RFSHCTL0.refresh_burst = 0 (see Register Descriptions). It can be programmed to burst up to 8 refreshes (RFSHCTL0.refresh_burst = 7). In LPDDR2/3 mode, with per-bank refresh enabled (RFSHCTL0.per_bank_refresh = 1), the maximum refresh burst supported by UDDRC is 64 (RFSHCTL0.refresh_burst = 63). Burst refresh can be used to minimize the bandwidth lost to closing pages for refresh and to increase the likelihood that refreshes can be serviced during idle periods. It can also be programmed to any number in between to trade-off the benefits of each.

17.5.8.2.1 Single Refresh

When using single refresh (RFSHCTL0.refresh_burst = 0), the UDDRC issues refreshes every time the refresh timer (t_{REFI}) expires. This is the optimal mode of operation for systems that minimize the maximum latency associated with refresh cycles.

17.5.8.2.2 Burst Refresh

When burst refresh is enabled (RFSHCTL0.refresh_burst > 0), the UDDRC issues refreshes in bursts of (RFSHCTL0.refresh_burst+1) refreshes at one time. Bursting refreshes reduce the total latency associated with those refreshes by reducing the number of precharges and activates required for refresh, as banks must be precharged only once to perform the entire group of refreshes, instead of once for each refresh.

17.5.8.2.3 Speculative Refresh

When the burst refresh is enabled (RFSHCTL0.refresh_burst > 0), you can also make use of a feature called speculative refresh.

Burst refresh is implemented by counting the number of times t_{REFI} expires and issuing a group of refreshes when that number reaches the refresh burst number. Once t_{REFI} has expired at least once, the UDDRC can also perform speculative refreshes. This is done by automatically inserting refreshes when there are no transactions pending in the CAM to a rank/bank address.

The RFSHCTL0.refresh_to_x1_x32 register determines how long the UDDRC must be idle before considering inserting these speculative refreshes. Each time a speculative refresh is performed, the count of t_{REFI} expirations is decremented, thereby increasing the time before a burst of refreshes is required. This also ensures that speculative refreshes never occur more often than is required to keep the SDRAM properly refreshed.

If a new read or write transaction is accepted by the UDDRC during speculative refresh, the UDDRC services it as soon as legally possible. Most often it entails waiting for the required NOP cycles after a refresh before performing an activate and then servicing the read or write. If the UDDRC has begun closing pages for a speculative refresh but has not yet issued the refresh when the new transaction arrives, the speculative refresh is canceled.

17.5.8.2.4 Per-bank Refresh (LPDDR2/LPDDR3 only)

If RFSHCTL0.per_bank_refresh is set to 1 (see Register Descriptions), the UDDRC performs per-bank refreshes instead of all-bank refreshes. In this case, RFSHTMG.t_rfc_nom_x1_x32 and RFSHTMG.t_rfc_min should be set to the appropriate values for per-bank refresh (tREFIpb and tRFCpb respectively). In this mode, the UDDRC keeps track of which bank is being refreshed at any time, and is able to schedule commands to other banks immediately before and after the per-bank refresh commands, resulting in potential efficiency gains. To improve the accuracy of per-bank refresh timing, set RFSHTMG.t_rfc_nom_x1_sel to 1 and program RFSHTMG.t_rfc_nom_x1_x32 accordingly (see Register Descriptions).

If the refresh burst (RFSHCTL0.refresh_burst) is programmed with a large value in per-bank Refresh mode, and bursting per-bank refreshes start, it may take a longer time than bursting all-bank refreshes. The three possible cases where bursting per-bank refreshes may occur are:

1. Random traffic
   The UDDRC may not be able to issue a speculative refresh because the CAM always has transactions on some banks. This can be avoided with appropriate register settings. For example, setting smaller values to RFSHCTL0.refresh_burst or RFSHCTL0.refresh_to_x1_x32.
2. Toggling RFSHCTL3.refresh_update_level
3. Hardware Fast Frequency Change (HWFFC)

After operation 2 or 3, the UDDRC starts bursting refreshes to compensate for any updated refresh timing parameters.

17.5.8.2.5 Constraints on refresh_timerX_start_value_x32

The refresh_timerX_start_value_x32 register fields control the relative timing of refreshes to different ranks.

The register fields must obey the following constraint:

refresh_timerX_start_value_x32 + RoundUp(RFSHTMG.t_rfc_min/32) < RFSHTMG.t_rfc_nom_x1_x32

If RFSHTMG.t_rfc_nom_x1_sel is set, RoundDown(RFSHTMG.t_rfc_nom_x1_x32/32) should be used in the above constraint.

Also, note that the register field refresh_timerX_start_value_x32 cannot be changed after initialization. So the value of the register RFSHTMG.t_rfc_nom_x1_x32 used above should be anticipated as the minimum value which will be used, considering frequency change, fine granularity refresh, etc.

For LPDDR2/3, if DERATEEN.derate_enable =1, use minimum RFSHTMG.t_rfc_nom_x1_x32/4 as value in calculation of refresh_timerX_star_value_x32 to consider possible effect of derating in high temperature case.

17.5.8.2.6 Registers Related to Refresh Controls

- UDDRC_RFSHCTL0
- UDDRC_RFSHCTL1
- UDDRC_RFSHCTL2
- UDDRC_RFSHCTL4

- UDDRC_RFSHCTL3
- UDDRC_RFSHTMG
- UDDRC_RFSHTMG1

For more information about these registers, see Register Descriptions.

17.5.9 ZQ Calibration

This feature is applicable to DDR3 and LPDDR2/LPDDR3. The UDDRC controller uses the ZQ calibration command to calibrate SDRAM RON (Resistor On) and ODT (On-Die Termination) values over PVT (Process, Voltage, Temperature). DDR3 and LPDDR2/LPDDR3 SDRAMs need more time to calibrate RON and ODT at initialization and relatively less time to perform periodic calibrations. For more information, refer to the following specifications:

- DDR3 (JEDEC JESD79-3F)
- LPDDR2 (JEDEC JESD209-2E)
- LPDDR3 (JEDEC JESD209-3B)

17.5.9.1 DDR3 Devices

ZQCL (ZQ Calibration Long) command is used as follows:

- To perform the initial calibration during the power-up initialization sequence. This command is allowed a timing period of tZQinit determined by INIT5. dev_zqinit_x32 (see Register Descriptions) to perform full calibration and the transfer of values.
- To perform long ZQ Calibration after exiting from Self-refresh mode. This command is allowed a timing period of tZQOPER, determined by ZQCTL0._t_zq_long_nop. This command is automatically issued when ZQCTL0.dis_srx_zqcl (ZQCTL0.dis_mpsmx_zqcl) is set to 0. To disable issuing ZQCL after self-refresh exit, set ZQCTL0.dis_srx_zqcl (ZQCTL0.dis_mpsmx_zqcl) to 1.

ZQCS (ZQ Calibration Short) command is used to perform periodic calibration to account for VT (Voltage/ Temperature) variations. A shorter timing window is provided to perform calibration and transfer of values as defined by the timing parameter tZQCS (determined by ZQCTL0._t_zq_short_nop). ZQCS can be performed automatically on a regular interval or through direct software request. For more information, see Automatic and Software Initiated ZQCS.

In DDR3 mode, the ZQ Calibration commands are sent out encoded on the DFI command bus as mentioned in the JEDEC Specification. The UDDRC performs no other activities for the duration of tZQinit, tZQOPER and tZQCS. The quiet time on the SDRAM channel helps in accurate calibration of SDRAM RON and ODT. All banks are precharged and t_{RP} met before the UDDRC issues the ZQ Calibration commands.

17.5.9.2 LPDDR2/LPDDR3 Devices

The UDDRC supports all the ZQ Calibration commands that are supported by the JEDEC Specification.

- ZQInit (ZQ Initial Calibration) command performs the initial calibration during the power-up initialization sequence. This command is allowed a time period of tZQinit (determined by INIT5.dev_zqinit_x32).
- ZQCL (ZQ Long Calibration) command performs long ZQ Calibration after exiting from Self-refresh mode. This command is allowed a timing period of tZQCL (determined by ZQCTL0._t_zq_long_nop). This command is issued automatically when ZQCTL0. dis_srx_zqcl is set to 0. To disable issuing of ZQCL after self-refresh exit, set ZQCTL0. dis_srx_zqcl to 1.
- ZQCS (ZQ Short Calibration) command is used to perform periodic calibration to account for VT (Voltage/ Temperature) variations. A shorter timing window is provided to perform calibration and transfer of values as defined by the timing parameter tZQCS (determined by ZQCTL0._t_zq_short_nop). ZQCS can be performed automatically on a regular interval or through direct software request. For more information, see Automatic and Software Initiated ZQCS.
- ZQReset (ZQ Calibration Reset) command is used to reset the RON calibration to a default accuracy of ±30% across process, voltage and temperature. This command is used to ensure RON accuracy of ±30% when ZQCS and ZQCL are not used and is allowed a time period of tZQRESET, determined by ZQCTL1.t_zq_reset_nop. The command is issued by using the registers ZQCTL2.zq_reset and ZQSTAT.zq_reset_busy (see Register Descriptions). For more information, see LPDDR2/LPDDR3 ZQ Reset Command.

In LPDDR2/LPDDR3 mode, ZQ Calibration commands are sent out as Mode Register Write commands to the DRAM. The MRW is done to MR10 and the calibration codes for the different commands are as follows:

ZQInit – 0xFF, ZQCL – 0xAB, ZQCS – 0x56 and ZQRest – 0xC3

The UDDRC performs no other activities for the duration of tZQinit, tZQCL, tZQCS, and tZQRESET. The quiet time on the SDRAM channel helps in accurate calibration of SDRAM RON and ODT. All banks are precharged and t_{RP} met before the UDDRC issues the ZQ Calibration commands.

17.5.9.3 Automatic and Software Initiated ZQCS

The UDDRC issues a ZQCS command in the following ways:

- Automatic ZQCS by the UDDRC: in this case, UDDRC sends ZQCS commands to SDRAM periodically. The interval is determined by ZQCTL1.t_zq_short_interval_x1024. This method is used if ZQCTL0.dis_auto_zq is set to 0 (see Register Descriptions).
- ZQCS using direct software request: in this case, the SoC core sends a ZQCS command through software by setting DBGCMD.zq_calib_short to 1. When the ZQCS request is stored in the UDDRC, the register bit is automatically cleared. It is recommended not to set DBGCMD.zq_calib_short signal, in Init, Self-refresh, Deep Power-down operating modes or Maximum Power Saving mode (MPSM). The SoC core can initiate a ZQCS operation only if DBGSTAT.zq_calib_short_busy is low. The DBGSTAT.zq_calib_short_busy signal goes high in the clock after the UDDRC accepts a ZQCS request. It goes low when the ZQCS operation is initiated in the UDDRC. For proper SDRAM operation, user/SoC core should schedule this command frequently. This method is used if ZQCTL0.dis_auto_zq is set to 1.

For self-refresh, command is scheduled after SR/SR-Powerdown is exited. For Deep Power Down or MPSM, command is not scheduled although ZQSTAT.zq_calib_short_busy is de-asserted.

17.5.9.4 LPDDR2/LPDDR3 ZQ Reset Command

In LPDDR2/LPDDR3 mode, the ZQ Reset command is issued by setting ZQCTL2.zq_reset to 1 (see Register Descriptions). When the ZQ Reset operation is complete, the UDDRC automatically clears this register bit. In LPDDR2/LPDDR3 mode, it is recommended not to set this signal in Init, Self-refresh or Deep Power-down operating modes. The SoC core can initiate a ZQ Reset operation only if ZQSTAT.zq_reset_busy is low. This signal goes high in the clock after the UDDRC accepts a ZQ Reset request. It goes low when the ZQ reset command is issued to the SDRAM and the associated NOP period is completed.

For self-refresh, command is scheduled after SR/SR-Powerdown is exited. For Deep Power Down, command is not scheduled although ZQSTAT.zq_reset_busy is de-asserted.

17.5.9.5 Registers Related to ZQ Calibration

- UDDRC_ZQCTL0
- UDDRC_ZQCTL1
- UDDRC_ZQCTL2
- UDDRC_ZQSTAT

For more information about these registers, see Register Descriptions.

17.5.10 ODT Control

By default, ODT to memories is driven to all zeros.

The register inputs control the following:

- ODTMAP.rank*_wr_odt: the value desired for ODT following a write command (see Register Descriptions).
- ODTCFG.wr_odt_delay: the number of cycles to delay following a write command before driving the programmed values for write ODT, which depends primarily on CAS latency.
- ODTCFG.wr_odt_hold: the number of cycles to hold the programmed write value after it is first driven.
- ODTMAP.rank*_rd_odt: the value desired for ODT following a read command.
- ODTCFG.rd_odt_delay: the number of cycles to delay following a read command before driving the programmed values for write ODT, which depends primarily on CAS latency.
- ODTCFG.rd_odt_hold: the number of cycles to hold the programmed read value after it is first driven.

Notes:
1. ODT control for memories is not required for LPDDR2. It is a DDR2/DDR3/LPDDR3 specific feature.
2. For LPDDR2, set ODTMAP.rank*_wr/rd_odt to all zeroes.

All of these must be set by the SoC core before taking the UDDRC out of reset. They are then applied to every read or write issued by the UDDRC.

For recommended settings for ODT-related registers in each protocol, see Register Descriptions.

17.5.10.1 Registers Related to ODT Control

The following are the registers related to the ODT Control:

- UDDRC_ODTCFG
- UDDRC_ODTMAP

For more information about these registers, see Register Descriptions.

17.5.11 High-Level SDRAM Initialization Procedure

Proceed as follows to initialize the SDRAM. Code example is given in provided software (Linux, Harmony).

Note: This sequence can also be used as a re-initialization phase from Self-refresh mode. In such case, some commands must be skipped or added. See SDRAM Self-Refresh Mode in the section "Electrical Characteristics" for more details.

17.5.11.1 Global Configuration

1. Update the SFRBU DDR Power Control register (SFRBU_DDRPWR) to take the DDR I/Os out of Retention state.
   – Wait for the command to complete by polling bit SFRBU_DDRPWR.RETENTION until it sets to 1.
2. Update the RSTC Generic Reset register (RSTC_GRSTR) to reset the DDR PHY and DDR controllers.
3. Perform a dummy read to allow 128 cycles for synchronization.
4. Update RSTC_GRSTR to release the DDR3PHY reset.
5. Perform a dummy read to allow 128 cycles for synchronization.

17.5.11.2 Step 1

1. Clear the DFI Miscellaneous Control register (UDDRC_DFIMISC).
2. Update the Host register 0 (UDDRC_MSTR) to enter details about the DDR used, indicate whether BURSTCHOP is used and set the required burst length.
3. If using LPDDR2/3 above 85°C: program the Temperature Derate Enable (UDDRC_DERATEEN) and Temperature Derate Interval (UDDRC_DERATEINT) registers.
4. Update the Low Power Control register (UDDRC_PWRCTL) to enable assertion of en_dfi_dram_clk_disable.
5. Update the Low Power Timing register (UDDRC_PWRTMG) with:
   – Number of clocks with command channel idle before UDDRC automatically puts SDRAM into Self-refresh mode
   – Number of clocks with command channel idle before UDDRC automatically puts SDRAM into Power-down mode
   – Minimum number of DFI clocks in Deep Power-down mode once PWRCTL.DEEPPOWERDOWN_EN is de-asserted
6. Update the Hardware Low Power Control register (UDDRC_HWLPCTL) to:
   – enable exiting from Automatic Clock Stop, Automatic Power-down or Automatic Self-refresh mode,
   – program the number of DFI clock cycles necessary once the command channel is idle before the active_ddrc output is driven low.
7. Update the Refresh Control register 0 (UDDRC_RFSHCTL0) with:
   – Refresh burst value
   – Refresh period
   – Critical refresh threshold margin value
8. Clear the UDDRC Refresh Control register 3 (UDDRC_RFSHCTL3).
9. According to the memory type, fill the following fields in the UDDRC Refresh Timing register (UDDRC_RFSHTMG):
   – T_RFC_MIN
   – T_RFC_NOM_X1_X32
10. Clear the CRC Parity Control register 0 (UDDRC_CRCPARCTL0).
11. Update SDRAM Initialization registers 0 to 5 (UDDRC_INIT0 to UDDRC_INIT5).

12. Clear the DIMM Control register (UDDRC_DIMMCTL).
13. Update SDRAM Timing registers 0 to 8 (UDDRC_DRAMTMG0 to UDDRC_DRAMTMG8) (and UDDRC_DRAMTMG14 for LPDDR1/2/3).
14. Update ZQ Control registers 0 and 1 (UDDRC_ZQCTL0 and UDDRC_ZQCTL1).
15. Update DFI Timing registers 0 and 1 (UDDRC_DFITMG0 and UDDRC_DFITMG1).
16. Update the DFI Low Power Configuration register 0 (UDDRC_DFILPCFG0).
17. Update DFI Update registers 0 to 2 (UDDRC_DFIUPD0 to UDDRC_DFIUPD2).
18. Disable the PHY host interface by clearing the DFI PHY Host register (UDDRC_DFIPHYMSTR).
19. Update the SAR Base Address register 0 (UDDRC_SARBASE0).
20. Update the SAR Size register 0 (UDDRC_SARSIZE0).
21. Update Address Map registers 1 to 11 (UDDRC_ADDRMAP1 to UDDRC_ADDRMAP11) depending on the type of DDR memory used.
22. If a DDR2 or DDR3 is being configured, update the ODT Configuration (UDDRC_ODTCFG) and ODT/Rank Map (UDDRC_ODTMAP) registers.
23. Update Scheduler Control registers 0 and 1 (UDDRC_SCHED and UDDRC_SCHED1).
24. Update the High Priority Read CAM register 1 (UDDRC_PERFHPR1).
25. Update the Low Priority Read CAM register 1 (UDDRC_PERFLPR1).
26. Update the Write CAM register 1 (UDDRC_PERFWR1) so that a low priority write timeout will be the same as a high priority write.
27. Update the Debug register 0 (UDDRC_DBG0).
28. Update the Port Common Configuration register (UDDRC_PCCFG).
29. For each port (0 to 4), update:
    – Port Configuration Read register
    – Port Configuration Write register
    – Port Read QoS Configuration registers 0 and 1
    – Port Write QoS Configuration registers 0 and 1

In case of re-initialization only:

1. Update the SDRAM Initialization register 0 (UDDRC_INIT0) to skip the SDRAM initialization while keeping the controller in Self-refresh mode.
2. Update UDDRC_PWRCTL to keep the memory in Self-refresh mode.
3. Clear UDDRC_DFIMISC.

17.5.11.3 Step 2

Update the RSTC Generic Reset register (RSTC_GRSTR) to bring the DDR Controller out of Reset state.

17.5.11.4 Step 3

Update:

1. DDR3PHY DRAM Configuration register
2. DDR3PHY PHY General Configuration register
3. DDR3PHY PHY Timing registers 0 to 2
4. DDR3PHY Mode registers 0 to 3
5. DDR3PHY ODT Configuration register
6. DDR3PHY DRAM Timing Parameters registers 0 to 2
7. DDR3PHY DDR System General Configuration register
8. DDR3PHY DATX8 Common Configuration register
9. DDR3PHY ZQ Impedance Control register 1 (if a DDR2 or DDR3 is being configured)

In case of re-initialization only: bypass the impedance calibration of ZQ control blocks by setting ZCALBYP in the DDR3PHY Initialization register (DDR3PHY_PIR).

17.5.11.5 Step 4

1. Wait for the DDR3PHY initialization to complete by polling the IDONE bit in the DDR3PHY PHY General Status register (DDR3PHY_PGSR).

2. In case of re-initialization only: override the ZQ Control impedance calibration by:
   – writing 1 to ZDEN in DDR3PHY ZQ Impedance Control register 0 (DDR3PHY_ZQ0CR0),
   – filling the ZQ impedance field with the previously saved impedance values,
   – restoring data corrupted by the training.

17.5.11.6 Step 5

1. Start the DDR system initialization. Use the controller by setting the DDR3PHY_PIR.INIT and DDR3PHY_PIR.CTLDINIT bits.
2. Wait for the DDR PHY initialization to complete by polling DDR3PHY_PGSR.IDONE.
3. In case of re-initialization only:
   – Update the SFRBU DDR Power Control register (SFRBU_DDRPWR) to clear the SFRBU_DDRPWR.RETENTION bit and take the DDR I/Os out of Retention state.
   – Wait for the command to complete by polling the SFRBU_DDRPWR.RETENTION bit until it sets to 1.
   – Remove the ZQ calibration override by writing 0 to DDR3PHY_ZQ0CR0.ZDEN.
   – Trigger ZQ calibration.
   – Wait for calibration to finish.
   – Read DDR3PHY_ZQ0CR0.ZCAL to check for a ZQ calibration error.
4. For full strength (18-Ohm) DDR2, perform a custom calibration. Refer to the provided sample initialization code.

17.5.11.7 Step 6

Update the Software Register Programming Control Enable register (UDDRC_SWCTL) to enable quasi-dynamic register programming.

17.5.11.8 Step 7

Update UDDRC_DFIMISC to set the DFI_INIT_COMPLETE_EN bit.

17.5.11.9 Step 8

Set UDDRC_SWCTL.SW_DONE to indicate that UDDRC programming is completed.

17.5.11.10 Step 9

In the Software Register Programming Control Status register (UDDRC_SWSTAT), poll the SW_DONE_ACK bit until it changes to 1, acknowledging that programming is complete.

In case of re-initialization only:

1. Update UDDRC_PWRCTL.SELFREF_SW to exit Self-refresh mode.
   – Wait until OPERATING MODE, in the Operating Mode Status register (UDDRC_STAT), changes to 0x1.

17.5.11.11 Step 10

Wait until UDDRC_STAT.OPERATING MODE changes to 0x1.

17.5.11.12 Step 11

1. Update UDDRC_RFSHCTL3 to disable auto-refreshes by setting DIS_AUTO_REFRESH to 1.
2. Toggle UDDRC_RFSHCTL3.REFRESH_UPDATE_LEVEL.
3. Update UDDRC_SWCTL to enable quasi-dynamic register programming.
4. Update UDDRC_DFIMISC to set DFI_INIT_COMPLETE_EN.
5. Set UDDRC_SWCTL.SW_DONE to indicate that UDDRC programming is completed.
   – Poll the UDDRC_SWSTAT.SW_DONE_ACK bit until it changes to 1, acknowledging that programming is complete.
6. Update Port Control registers for ports 0 to 4 (UDDRC_PCTRL_0 to UDDRC_PCTRL_4) to enable the AXI ports.

17.5.11.13 Step 12

In the DDR3PHY PHY General Configuration register (DDR3PHY_PGCR), set the RANKEN field to enable training for rank 1.

17.5.11.14 Step 13

Update DDR3PHY_PIR to launch RV and QS trainings.

- Wait for the DDR3PHY initialization to complete by polling DDR3PHY_PGSR.IDONE.

17.5.11.15 Step 14

Read DDR3PHY_PGSR to check whether the training was successful or if errors occurred.

In case of re-initialization only: restore data corrupted by the training using the DCU command cache.

17.5.11.16 Step 15

1. Update UDDRC_RFSHCTL3 to enable auto-refreshes by clearing DIS_AUTO_REFRESH.
2. Toggle UDDRC_RFSHCTL3.REFRESH_UPDATE_LEVEL.
3. Update UDDRC_SWCTL to enable quasi-dynamic register programming.
4. Update UDDRC_DFIMISC to set DFI_INIT_COMPLETE_EN.
5. Set UDDRC_SWCTL.SW_DONE to indicate that UDDRC programming is completed.
   – Poll the UDDRC_SWSTAT.SW_DONE_ACK bit until it changes to 1, acknowledging that programming is complete.
6. Update Port Control registers for ports 0 to 4 (UDDRC_PCTRL_0 to UDDRC_PCTRL_4) to enable the AXI ports.

17.5.11.17 Step 16

Program the TrustZone controllers to enable SDRAM use.

This initialization allows TZC400 to accept all accesses (secure or not secure) in the DDR address space.

Note: If TZC400 is not programmed, all accesses are blocked (without any response error).

17.5.12 Mode Register Reads and Writes

This section explains how to perform mode register reads and writes through software. Mode Register Reads (MRR) are applicable only to LPDDR2/LPDDR3, and are used to read configuration and status data from mode registers in the SDRAM. Mode Register Writes (MRW or MRS) are applicable to all supported DDR protocols, and are used to write configuration data to mode registers in the SDRAM. Access to the mode register is initiated by programming the MRCTRL0 and MRCTRL1 registers (see Register Descriptions). This must be done in three steps:

1. Poll MRSTAT.mr_wr_busy until it is ‘0’. This checks that there is no outstanding MR transaction. No writes should be performed to MRCTRL0 and MRCTRL1 if MRSTAT.mr_wr_busy = 1.
2. Write the MRCTRL0.mr_type, MRCTRL0.mr_addr, MRCTRL0.mr_rank and (for MRWs) MRCTRL1.mr_data to define the MR transaction.
3. In a separate APB transaction, write the MRCTRL0.mr_wr to 1. This bit is self-clearing, and triggers the MR transaction. The UDDRC then asserts the MRSTAT.mr_wr_busy while it performs the MR transaction to SDRAM, and no further accesses can be initiated until it is deasserted.

17.5.12.1 Mode Register Write

MRW transactions can be specified for either any single rank, or any combination of several ranks, by programming MRCTRL0.mr_rank.

If any part of the SDRAM’s MR register is updated by software, it is also the responsibility of the software to update corresponding INIT*.*mr* so that it is aligned to the SDRAM’s MR register. For LPDDR2/3, INIT* registers are used to perform SDRAM initialization after DPDX.

17.5.12.2 Mode Register Read

MRR transactions should only be performed to one rank at a time, to avoid bus contention. When an MRR is performed, the Mode register contents are available on hif_mrr_data, qualified by hif_mrr_data_valid, after the Mode register read command is issued by the UDDRC to the SDRAM. Note that the entire width of the SDRAM data is mapped to hif_mrr_data. You must select the appropriate byte, depending on whether the bytes are swapped on the board or not.

17.5.12.3 Registers Related to Mode Register Reads and Writes

The following are the registers related to the Mode register reads and writes:

- UDDRC_MRCTRL0
- UDDRC_MRCTRL1
- UDDRC_INIT0
- UDDRC_INIT1
- UDDRC_INIT2
- UDDRC_INIT3
- UDDRC_INIT4
- UDDRC_INIT5
- UDDRC_INIT6
- UDDRC_INIT7

For more information about these registers, see Register Descriptions.

17.5.13 2T Memory Command Timing

Memory command duration is one memory clock cycle, which is referred to as 1T command timing.

Optionally, to provide sufficient address setup time in heavily loaded memory bus configurations, memory address and memory command are asserted for two memory clock cycles which is referred to as 2T command timing.

Figure 17-5. 1T Memory Command Timing

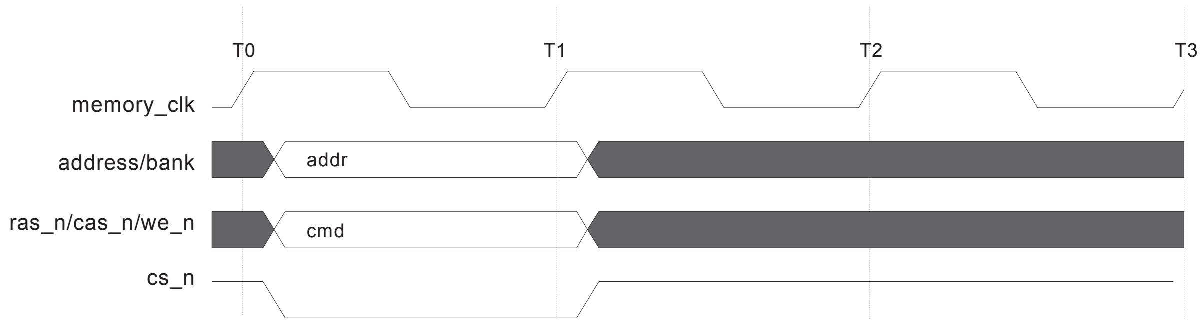


Figure 17-6. 2T Memory Command Timing

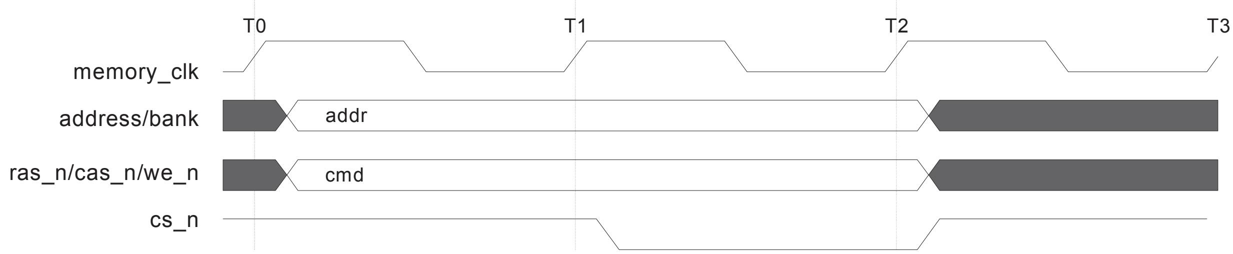

Notes:
1. 2T mode is not supported when BL2 is selected.
2. 2T mode is not supported in LPDDR2/LPDDR3 modes.

Enabling 2T Memory Command Timing:

This feature is enabled using the register MSTR.en_2t_timing_mode.

For more information about these registers, see Register Descriptions.

17.5.14 Power Saving Features

The UDDRC supports various SDRAM power saving modes, such as Precharge Power-down, Self-refresh, Deep Power-down, Maximum Power Saving, and support for disabling clock to the DRAM through dfi_dram_clk_disable.

Refer to Self-refresh mode entering and exiting procedures in the section "Electrical Characteristics".

17.5.14.1 SDRAM Power Saving Features

17.5.14.1.1 Precharge Power-down

Entering Precharge Power-down

When PWRCTL.powerdown_en = 1 (see Register Descriptions), UDDRC automatically enters precharge power-down when the period specified by PWRTMG.powerdown_to_x32 has passed while the UDDRC is idle (except for issuing refreshes).

Entering Precharge Power-down mode involves the following steps:

1. If there is a self-refresh exit previously, wait for at least one refresh command (or 8 per-bank refresh commands if LPDDR2/3 per-bank refresh is enabled) to all active ranks. Auto-refresh logic must be enabled, or refresh should be issued using direct software requests of refresh command through DBGCMD.rank*_refresh.
2. Precharging (closing) all open pages. Pages are closed one-at-a-time in no specified order.
3. Waiting for t_{RP} (row precharge) idle period.
4. Issuing the command to enter precharge power-down (NOP/deselect with CKE = 0).
5. This step occurs only if DFI low-power interface for power-down is enabled (DFILPCFG0.dfi_lp_en_pd). Attempts an entry to Low-power mode through DFI low-power interface and with dfi_lp_wakeup set by DFILPCFG0.dfi_lp_wakeup_pd. The low power entry attempt is delayed with DFITMG0.dfi_t_ctrl_delay + DRAMTMG7.t_ckpde clock cycles. This is needed to satisfy SDRAM timings related to disabling clocks when the PHY is programmed to gate the clock to save maximum power.

If the UDDRC receives a read or write request from the SoC core during step 2 or step 3 above, the power-down entry is immediately aborted. The same is true if PWRCTL.powerdown_en is driven to ‘0’ during step 2 or step 3. Once the power-down entry command is issued, then proper power-down exit is required, as described in “Entering Precharge Power-down” below.

Exiting Precharge Power-down

Once the UDDRC has put the DDR SDRAM device(s) in Precharge Power-down mode, the UDDRC automatically performs the precharge power-down exit sequence for any of the following reasons:

- A refresh cycle is required to any rank in the system.
- The UDDRC receives a new request from the SoC core.
- A self-refresh entry is requested.
- PWRCTL.powerdown_en is set to 0 (see Register Descriptions).

The UDDRC follows these steps when exiting Precharge Power-down mode:

1. Inserting any NOP/deselect commands required to satisfy the t_{CKE} requirement after entering precharge power-down.
2. This step occurs only if DFI Low-power mode entry during power-down entry is successful. Performs an exit from DFI Low-power mode. DFI Low-power mode is exited after the wakeup time specified by DFILPCFG0.dfi_lp_wakeup_pd, but not earlier than DFITMG1.dfi_t_dram_clk_enable + DRAMTMG6.t_ckpdx clock cycles.
3. Issuing the power-down exit command (NOP/deselect with CKE = 1).
4. Issuing NOP/deselect for the period defined by t_{XP}.

Notes:

1. DDR2: Fast Exit versus Slow Exit Active Power-down
The DDR2 Specification describes two different variations on active power-down exit, depending on the programmed value of MR bit 12. As the UDDRC uses precharge power-down rather than active power-down, this programming has no effect on the UDDRC or th SDRAM devices.
2. DDR3: Fast Exit versus Slow Exit Precharge Power-down
The DDR3 Specification describes two different variations on precharge power-down exit, depending on the programmed value of MR0 bit 12. If slow precharge power-down is used (MR0[12] = 0), DRAMTMG1.t_xp should be set to tXPDLL. If fast precharge power-down is used (MR0[12] = 1), DRAMTMG1.t_xp should be set to tXP.
3. Other supported DDR protocols do not specify the difference between fast and slow power-down exit.

17.5.14.1.2 Deep Power-Down

This power saving mode is applicable for LPDDR2 and LPDDR3 devices only.

Entering Deep Power-down

By setting the PWRCTL.deeppowerdown_en bit (see Register Descriptions), you can put the SDRAM device(s) into Deep Power-down mode, if all the following conditions are true:

- The period specified by PWRTMG.powerdown_to_x32 has passed while the UDDRC is idle (except for issuing refreshes).
- PWRCTL.selfref_sw = 0
- PWRCTL.selfref_en = 0
- If HWLPCTL.hw_lp_en = 1, DPD is entered only when the hardware low-power interface has completed a self-refresh exit. (This can be checked by observing STAT.operating_mode and STAT.selfref_type).
- If HWLPCTL.hw_lp_exit_idle_en = 1, DPD is entered only when all bits of cactive_in_ddrc = 0

Entering Deep power-down involves the following steps:

1. If there is a self-refresh exit previously, wait for at least one refresh command (or 8 per-bank refresh commands if LPDDR2/3 per-bank refresh is enabled) to all active ranks. Auto-refresh logic must be enabled, or refresh should be issued using direct software requests of refresh command through DBGCMD.rank*_refresh.
2. Precharging (closing) all open pages. Pages are closed one-at-a-time in no specified order.
3. Waiting for t_{RP} (row precharge) idle period.
4. Issuing the command to enter deep power-down. For multi-rank systems, all chip-selects are asserted so that all ranks enter deep power-down simultaneously. The deep power-down entry command is:
   CKE = 0, CSN = 0, CA0 = 1, CA1 = 1, CA2 = 0
5. This step occurs only if DFI low-power interface for deep power-down is enabled (DFILPCFG0.dfi_lp_en_dpd). It attempts an entry to Low-power mode through DFI low-power interface with dfi_lp_wakeup set by DFILPCFG0.dfi_lp_wakeup_dpd. The low power entry attempt is delayed with DFITMG0.dfi_t_ctrl_delay + DRAMTMG6.t_ckdpde clock cycles, this is needed to satisfy SDRAM timings related to disabling clocks when the PHY is programmed to gate the clock, to save maximum power.

If the UDDRC receives a read or write request from the SoC core during step 1 or step 3 above, the deep power-down entry is immediately aborted. The same is true if PWRCTL.deep_powerdown_en is driven to ‘0’ during step 1 or step 3. Once the deep power-down entry command is issued, proper deep power-down exit is required, as described in the following section.

Note: Contents of SDRAM may be lost upon entry into Deep Power-down mode.

Exiting Deep Power-down

Once the UDDRC puts the DDR SDRAM device(s) in Deep Power-down mode, the UDDRC automatically exits deep power-down and re-runs the initialization sequence when PWRCTL.deeppowerdown_en is reset to 0 (see Register Descriptions). An exit from DFI Low-power mode is performed prior to exiting deep power-down (this occurs only if DFI Low- power mode entry during deep power-down entry is successful). DFI Low-power mode is exited after the wakeup time specified by DFILPCFG0.dfi_lp_wakeup_dpd, but not earlier than DFITMG1.dfi_t_dram_clk_enable + DRAMTMG6.t_ckdpdx clock cycles.

Exiting Deep power-down involves the following steps when SDRAM initialization is performed by the PHY (INIT0.skip_dram_init = 2’b01 or 2’b11):

1. To prevent the UDDRC asserting dfi_cke before the SDRAM initialization is complete, it is necessary to set INIT0.skip_dram_init = 2’b11 before clearing PWRCTL.deeppowerdown_en.
2. If step 1 is performed, to ensure that controller updates will not occur when INIT0.skip_dram_init will be changed back to 2’b01 (which could make DFI bus active when dfi_ctrlupd_req), it is necessary to set DFIUPD0.dis_auto_ctrlupd and DBG1.dis_hif and to stop sending software controller updates before clearing PWRCTL.deeppowerdown_en.
3. Clear DFIMISC.dfi_init_complete_en=“0” register, before clearing PWRCTL.deeppowerdown_en to ensure that the UDDRC will wait until the PHY completes its initialization.
4. Reset PWRCTL.deeppowerdown_en to 0 and poll STAT.operating mode to detect when the UDDRC exits from DPD and then start the SDRAM initialization by setting the PUB_PIR register.

5. Once PHY Init is started and PIR is programmed, set back the old value of skip_dram_init, if it was updated as described in step 1.
6. Poll the relevant PUB's PGSR register to detect when the PUB Initialization is complete.
7. Change back the DFIUPD0.dis_auto_ctrlupd and DBG1.dis_hif values and/or restart sending software controller updates, if they were disabled as described in step 2.
8. Set DFIMISC.dfi_init_complete_en to 1 in order to allow the UDDRC's state machine to exit the Initialization state.

For more information, see SDRAM Initialization Sequence.

17.5.14.1.3 Assertion of dfi_dram_clk_disable

Assertion of dfi_dram_clk_disable occurs only if PWRTL.en_dfi_dram_clk_disable = 1.

dfi_dram_clk_disable is also dependent on the operating mode:

- In DDR2/DDR3, dfi_dram_clk_disable can be asserted only in Self-refresh mode.
- In LPDDR2/LPDDR3, dfi_dram_clk_disable can be asserted in the following modes:
  – in Self-refresh
  – in Power-down
  – in Deep Power-down
  – in Normal mode (“Clock Stop” feature)

The timing of the assertion and de-assertion of dfi_dram_clk_disable in various modes is as follows:

- In Self-refresh or Self-refresh Power-down mode:
  – Asserted at least DFITMG0.dfi_t_ctrl_delay + DRAMTMG5.t_cksre DFITMG1.dfi_t_dram_clk_disable cycles after SRE command.
  – De-asserted at least DFITMG1.dfi_t_dram_clk_enable + DRAMTMG5.t_cksrx - DFITMG0.dfi_t_ctrl_delay cycles before SRX command.
- In Power-down:
  – Asserted at least DFITMG0.dfi_t_ctrl_delay + DRAMTMG7.t_ckpde -DFITMG1.dfi_t_dram_clk_disable cycles after PDE command.
  – De-asserted at least DFITMG1.dfi_t_dram_clk_enable + DRAMTMG7.t_ckpdx -DFITMG0.dfi_t_ctrl_delay cycles before PDX command.
- In Deep Power-down:
  – Asserted at least DFITMG0.dfi_t_ctrl_delay + DRAMTMG6.t_ckdpde - DFITMG1.dfi_t_dram_clk_disable cycles after DPDE command.
  – De-asserted at least DFITMG1.dfi_t_dram_clk_enable + DRAMTMG6.t_ckdpdx -DFITMG0.dfi_t_ctrl_delay cycles before DPDX command.
- In Normal mode (Clock Stop):
  – Asserted at least DFITMG0.dfi_t_ctrl_delay - DFITMG0.dfi_t_dram_clk_disable cycles after any command other than SRE/PDE/DPDE.
  – De-asserted at least DFITMG1.dfi_t_dram_clk_enable + DRAMTMG6.t_ckcsx - DFITMG0.dfi_t_ctrl_delay cycles before any command other than SRX/PDX/DPDX.

For more information about the above modes, see Register Descriptions.

17.5.14.1.4 DLL-off Mode (DDR3)

DLL-off mode enables DDR3 SDRAMs to be operated at low frequencies. The UDDRC supports DLL-off mode, and transitions between DLL-on and DLL-off mode, under software control.

To enable DLL-off mode from initialization, the following register fields must be set:

- INIT3.emr[0], so that the SDRAM mode register is set for DLL-off mode
- MSTR.dll_off_mode = 1
- The DDR PHY should be put in PLL-bypass mode

To perform a transition between DLL-off and DLL-on modes, the software must implement the sequence specified in the JEDEC specification.

Note that geardown and programmable preamble are not supported in DLL-off mode.

17.5.14.2 Power Saving in PHY through DFI Low-Power Interface

Based on whether SDRAM is in Precharge Power-down, Self-refresh, Self-refresh Power-down or Deep Power-down mode (see SDRAM Power Saving Features), the PHY can be placed in power saving modes through the DFI low-power interface.

17.5.14.3 Software Sequence for Removal of Clocks

Software can be used to keep the SDRAM in self-refresh. The AXI and DDRC clocks can be removed when in self-refresh by following the sequence described in the following table.

Note: Dynamic and quasi dynamic registers cannot be programmed if any of the clocks has been removed. Clocks must be turned back on before starting the programming sequence. Also, the clock gating logic must ensure there are no glitches on the clocks when they are removed/enabled.

Table 17-4. Software Clock Removal Sequence

Step	Description	Comment
1	Write 0 to PCTRL_n.port_en	Blocks AXI ports from taking any more transactions
2	Poll PSTAT.rd_port_busy_n = 0 Poll PSTAT.wr_port_busy_n = 0	Waits until all AXI ports are idle
3	Write 1 to PWRCTL.selfref_sw	Causes the system to move to Self-refresh state
4	Poll STAT.selfref_type= 2’b10	Waits until Self-refresh state is entered
5	Remove AXI clocks	–
6	Remove DDRC core clock	–

The clocks should be re-enabled by following the sequence described in the following table.

Table 17-5. Re-enabling the Clocks

Step	Description	Comment
1	Enable AXI clocks	–
2	Enable DDRC core clock	–
3	Write 0 to PWRCTL.selfref_sw	Causes the system to exit from Self-refresh state
4	Poll STAT.selfref_type = 2’b00	Waits until Self-refresh state is exited
5	Write 1 to PCTRL_n.port_en	AXI ports are no longer blocked from taking transactions

17.5.14.4 Power Removal Flow

Table 17-6. Power Removal

Step	Description	Comment
1	Write 0 to PCTRL_n.port_en	Blocks AXI ports from taking any more transactions
2	Poll PSTAT.rd_port_busy_n = 0 Poll PSTAT.wr_port_busy_n = 0	Waits unit all AXI ports are idle
3	Write 1 to PWRCTL.selfref_sw	Causes system to move to Self-refresh state
4	Poll STAT.selfref_type= 2’b10	Waits until Self-refresh state is entered
5	Place IOs in Retention mode	Refer to the section “DDR/LPDDR Physical Interface (DDR3PHY)”
6	Remove power	–

Table 17-7. Re-enabling the Power

Step	Description	Comment
1	Enable Power	–
2	Reset controller/PHY by driving core_ddrc_rstn = 1’b0, aresetn_n = 1’b0, presetn = ’b0	_
3	Remove APB reset, presetn =1’b1, and rereprogram the registers to pre-power removal values	_
4	Program INIT0.skip_dram_init = 2’b11	Skips the DRAM init routine and starts up in Self-refresh mode
5	Programs PWRCTL.selfref_sw = 1’b1	Keeps the controller in Self-refresh mode
6	Program DFIMISC.dfi_init_complete_en to 1’b0	PHY initialization needs to be rerun, so set to 0 until initialization complete
7	Remove the core reset core_ddrc_rstn = 1’b1 aresetn_n = 1’b1	–
8	Run PHY initialization/training as required, including removing the IOs from Retention mode	Refer to the section “DDR3PHY”
9	Program DFIMISC.dfi_init_complete_en to 1’b1	Indicates to controller that PHY has completed re-training/initialization
10	Program PWRCTL.selfref_sw = 1’b0	Triggers Self-refresh exit
11	Poll STAT.selfref_type = 2’b00	Wait until Self-refresh state is exited
12	Poll STAT.operating_mode for Normal mode entry	–
13	Write PCTRL.port_en = 1	AXI ports are no longer blocked from taking transactions

17.5.14.5 Registers Related to Power-Saving Features

The following registers are related to the power saving features:

- UDDRC_DRAMTMG5.t_cke
- Precharge power-down controls:
  - UDDRC_PWRCTL.POWERDOWN_EN
  - UDDRC_PWRTMG.POWERDOWN_TO_X32
  - UDDRC_DRAMTMG1.T_XP
- Self-refresh controls:
  - UDDRC_PWRCTL.SELFREF_SW
  - UDDRC_PWRCTL.SELFREF_EN
  - UDDRC_HWLPCTL.HW_LP_EN
- Hardware low-power interface: csysreq_*/csysack_*/cactive_*
  - UDDRC_PWRTMG.SELFREF_TO_x32
  - UDDRC_STAT.SELFREF_TYPE
  - UDDRC_PWRCTL.STAY_IN_SELFREF
  - UDDRC_STAT.SELFREF_STATE
- Hardware low-power interface:
  - UDDRC_HWLPCTL.HW_LP_EXIT_IDLE_EN
  - UDDRC_HWLPCTL.HW_LP_IDLE_X32
- Deep power-down controls:
  - UDDRC_PWRCTL.DEEPPOWERDOWN_EN
  - UDDRC_PWRTMG.T_DPD_X4096

- Maximum Power-saving mode controls:
  - UDDRC_PWRCTL.MPSM_EN
  - UDDRC_DRAMTMG11.T_MPX_LH
  - UDDRC_DRAMTMG11.T_MPX_S
  - UDDRC_DRAMTMG11.T_CKMPE
- Assertion of dfi_dram_clk_disable to disable the clocks to the DRAM controls:
  - UDDRC_WRCTL.EN_DFI_DRAM_CLK_DISABLE
  - UDDRC_DFITMG1.DFI_T_DRAM_CLK_DISABLE
  - UDDRC_DFITMG1.DFI_T_DRAM_CLK_ENABLE
  - UDDRC_DRAMTMG5.T_CKSRE
  - UDDRC_DRAMTMG5.T_CKSRX
  - UDDRC_DRAMTMG6.T_CKPDE
  - UDDRC_DRAMTMG6.T_CKPDX
  - UDDRC_RAMTMG6.T_CKDPDE
  - UDDRC_DRAMTMG6.T_CKDPDX
  - UDDRC_DRAMTMG6.T_CKCSX

For more information about these registers, see Register Descriptions.

17.6 Register Summary

In the following register descriptions, "Programming Mode" specifies the register type:

- Static: can be written only when the controller is in reset.
- Dynamic: can be written at any time during operation.
- Quasi-dynamic: can be written when the controller is in reset and some specific conditions outside reset. There are four groups this type.

Offset	Name	Bit Pos.	7	6	5	4	3	2	1	0
0x00	UDDRC_MSTR	31:24								
		23:16					BURST_RDWR[3:0]			
		15:8	DLL_OFF_MODE		DATA_BUS_WIDTH[1:0]			EN_2T_TIMING_MODE	BURSTCHOP	
		7:0					LPDDR3	LPDDR2		DDR3
0x04	UDDRC_STAT	31:24								
		23:16								
		15:8				SELFREF_CAM_NOT_EMPTY				
		7:0			SELFREF_TYPE[1:0]			OPERATING_MODE[2:0]

17.6.1 UDDRC Host Register 0

Name: UDDRC_MSTR
Offset: 0x000
Reset: 0x00040001
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
					BURST_RDWR[3:0]			
Access					R/W	R/W	R/W	R/W
Reset					0	1	0	0

Bit	15	14	13	12	11	10	9	8
	DLL_OFF_MODE		DATA_BUS_WIDTH[1:0]			EN_2T_TIMING_MODE	BURSTCHOP	
Access	R/W		R/W	R/W		R/W	R/W	
Reset	0		0	0		0	0	

Bit	7	6	5	4	3	2	1	0
					LPDDR3	LPDDR2		DDR3
Access					R/W	R/W		R/W
Reset					0	0		1

Bits 19:16 – BURST_RDWR[3:0] SDRAM burst length used
This controls the burst size used to access the SDRAM. This must match the burst length mode register setting in the SDRAM. (For BC4/8 on-the-fly mode of DDR3, set this field to 0x0100). Burst length of 2 is not supported.
Burst length of 2 is only supported when the controller is operating in 1:1 frequency mode.
For DDR3 and LPDDR3, this must be set to 0x0100 (BL8).
Programming mode: Static

Value	Description
0001	Reserved
0010	Burst length of 4
0100	Burst length of 8
1000	Burst length of 16 (only supported for LPDDR2)
–	All other values are reserved.

Bit 15 – DLL_OFF_MODE
Set to 1 when the UDDRC and DRAM has to be put in DLL-off mode for low frequency operation.
Set to 0 to put UDDRC and DRAM in DLL-on mode for normal frequency operation.
Programming mode: Quasi-dynamic Group 2

Bits 13:12 – DATA_BUS_WIDTH[1:0]
Selects proportion of DQ bus width that is used by the SDRAM.
Note that half bus width mode is only supported when the SDRAM bus width is a multiple of 16. Bus width refers to DQ bus width.
Programming mode: Static

Value	Description
00	Full DQ bus width to SDRAM
01	Half DQ bus width to SDRAM
10	Quarter DQ bus width to SDRAM
11	Reserved

Bit 10 – EN_2T_TIMING_MODE
If 1, then UDDRC uses 2T timing. Otherwise, uses 1T timing. In 2T timing, all command signals (except chip select) are held for 2 clocks on the SDRAM bus. Chip select is asserted on the second cycle of the command.
2T timing is not supported in the following cases:

- in LPDDR2/LPDDR3 mode
- in Shared-AC dual channel mode and the register value is don't care.

Programming mode: Static

Bit 9 – BURSTCHOP
When set, enable burst-chop (BC4 or 8 on-the-fly) in DDR3. Burst Chop for Reads is not exercised. Burst Chop for Writes is exercised.
BC4 (fixed) mode is not supported.
Programming mode: Static

Bit 3 – LPDDR3 Select LPDDR3 SDRAM
Present only in designs configured to support LPDDR3.
Programming mode: Static

Value	Description
0	Non-LPDDR3 device in use.
1	LPDDR3 SDRAM device in use.

Bit 2 – LPDDR2 Select LPDDR2 SDRAM
Present only in designs configured to support LPDDR2.
Programming mode: Static

Value	Description
0	Non-LPDDR2 device in use
1	LPDDR2 SDRAM device in use.

Bit 0 – DDR3 Select DDR3 SDRAM
Only present in designs that support DDR3.
Programming mode: Static

Value	Description
0	Non-DDR3 SDRAM device in use
1	DDR3 SDRAM device in use

17.6.2 UDDRC Operating Mode Status Register

Name: UDDRC_STAT
Offset: 0x004
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
				SELFREF_CAM_NOT_EMPTY				
Access				R				
Reset				0				

Bit	7	6	5	4	3	2	1	0
			SELFREF_TYPE[1:0]			OPERATING_MODE[2:0]		
Access			R	R		R	R	R
Reset			0	0		0	0	0

Bit 12 – SELFREF_CAM_NOT_EMPTY Self-refresh with CAMs not empty
Set to 1 when Self-refresh is entered but CAMs are not drained. Cleared after exiting Self-refresh.
Programming Mode: Static

Bits 5:4 – SELFREF_TYPE[1:0]
Flags if Self-refresh is entered and if it was under Automatic Self-refresh control only or not.
Programming Mode: Static

Value	Description
00	SDRAM is not in Self-refresh. If retry is enabled by CRCPARCTRL1.crc_parity_retry_enable, this also indicates the SRE command is still in parity error window or retry is in progress.
11	SDRAM is in Self-refresh, which was caused by Automatic Self-refresh only. If retry is enabled, this ensures the SRE command is executed correctly without parity error.
10	SDRAM is in Self-refresh, which was not caused solely under Automatic Self-refresh control. It could have been caused by Hardware Low Power Interface and/or Software (PWRCTL.selfref_sw). If retry is enabled, this ensures the SRE command is executed correctly without parity error.
01	SDRAM is in Self-refresh, which was caused by PHY Host Request.

Bits 2:0 – OPERATING_MODE[2:0] Operating mode
This is 3-bit wide in configurations with LPDDR2/LPDDR3 support and 2-bit wide in all other configurations.
Programming Mode: Static

Value	Description
	Non-LPDDR2/LPDDR3 designs:
00	Init
01	Normal
10	Power-down
11	Self-refresh
	LPDDR2/LPDDR3 designs:

Value	Description
000	Init
001	Normal
010	Power-down
011	Self-refresh
1XX	Deep Power-down / Maximum Power Saving mode

17.6.3 UDDRC Mode Register Read/Write Control Register 0

Name: UDDRC_MRCTRL0
Offset: 0x010
Reset: 0x00000010
Property: R/W

Bit	31	30	29	28	27	26	25	24
	MR_WR							
Access	R/W							
Reset	0							

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
	MR_ADDR[3:0]							
Access	R/W	R/W	R/W	R/W				
Reset	0	0	0	0				

Bit	7	6	5	4	3	2	1	0
				MR_RANK				MR_TYPE
Access				R/W				R/W
Reset				1				0

Bit 31 – MR_WR
Setting this register bit to 1 triggers a mode register read or write operation. When the MR operation is complete, the UDDRC automatically clears this bit.
The other register fields of this register must be written in a separate APB transaction, before setting this mr_wr bit. It is recommended NOT to set this signal if in Init, Deep Power-down or MPSM operating modes.
Programming mode: Dynamic

Bits 15:12 – MR_ADDR[3:0] Address of the Mode register that is to be written to.
Don't Care for LPDDR2/LPDDR3 (see UDDRC_MRCTRL1.MR_DATA for mode register addressing in LPDDR2/LPDDR3).
This signal is also used for writing to control words of the register chip on RDIMMs/LRDIMMs. In that case, it corresponds to the bank address bits sent to the RDIMM/LRDIMM.
Programming mode: Dynamic

Value	Description
0000	MR0
0001	MR1
0010	MR2
0011	MR3
0100	MR4
0101	MR5
0110	MR6
0111	MR7

Bit 4 – MR_RANK
Controls which rank is accessed by MRCTRL0.mr_wr. Normally, it is desired to access all ranks, so all bits should be set to 1. However, for multi-rank UDIMMs/RDIMMs/LRDIMMs which implement address mirroring, it may be necessary to access ranks individually.
Examples (assume UDDRC is configured for 4 ranks):
Programming mode: Dynamic

Value	Description
0x1	Select rank 0 only
0x2	Select rank 1 only
0x5	Select ranks 0 and 2
0xA	Select ranks 1 and 3
0xF	Select ranks 0, 1, 2 and 3

Bit 0 – MR_TYPE
Indicates whether the Mode register operation is read or write. Only used for LPDDR2/LPDDR3.
Programming mode: Dynamic

Value	Description
0	Write
1	Read

17.6.4 UDDRC Mode Register Read/Write Control Register 1

Name: UDDRC_MRCTRL1
Offset: 0x014
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
	MR_DATA[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	MR_DATA[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 15:0 – MR_DATA[15:0]
Mode register write data for all non-LPDDR2/non-LPDDR3 modes.
For LPDDR2/LPDDR3, MRCTRL1[15:0] are interpreted as
[15:8] MR Address
[7:0] MR data for writes, don't care for reads. This is 16-bit wide for all configurations.
Programming mode: Dynamic

17.6.5 UDDRC Mode Register Read/Write Status Register

Name: UDDRC_MRSTAT
Offset: 0x018
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
								MR_WR_BUSY
Access								R
Reset								0

Bit 0 – MR_WR_BUSY
The SoC core may initiate a MR write operation only if this signal is low. This signal goes high in the clock after the UDDRC accepts the MRW/MRR request. It goes low when the MRW/MRR command is issued to the SDRAM. It is recommended not to perform MRW/MRR commands when 'MRSTAT.mr_wr_busy' is high.
Programming mode: Dynamic

Value	Description
0	Indicates that the SoC core can initiate a mode register write operation.
1	Indicates that mode register write operation is in progress.

17.6.6 UDDRC Temperature Derate Enable Register

Name: UDDRC_DERATEEN
Offset: 0x020
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
				DERATE_MR4_TUF_DIS				
Access				R/W				
Reset				0				

Bit	7	6	5	4	3	2	1	0
	DERATE_BYTE[3:0]					DERATE_VALUE[1:0]		DERATE_ENABLE
Access	R/W	R/W	R/W	R/W		R/W	R/W	R/W
Reset	0	0	0	0		0	0	0

Bit 12 – DERATE_MR4_TUF_DIS
Disable use of MR4 TUF flag (MR4[7]) bit.
For LPDDR2 and LPDDR3, contact your memory vendor for recommended usage.
This affects both the periodic derate logic (DERATEEN.derate_enable) and the derate_temp_limit_intr.
Programming mode: Quasi-dynamic Group 2, Group 4

Value	Description
0	Use MR4 TUF flag (MR4[7]).
1	Do not use MR4 TUF Flag (MR4[7]).

Bits 7:4 – DERATE_BYTE[3:0] Derate byte
Present only in designs configured to support LPDDR2/LPDDR3.
Indicates which byte of the MRR data is used for derating. The maximum valid value is 1.
Programming mode: Static

Bits 2:1 – DERATE_VALUE[1:0] Derate value
Present only in designs configured to support LPDDR2/LPDDR3.
Set to 0 for all LPDDR2 speed grades as derating value of +1.875 ns is less than a core_ddrc_core_clk period.
For LPDDR3, if the period of core_ddrc_core_clk is less than 1.875ns, this register field should be set to 1; otherwise it should be set to 0.
Programming mode: Quasi-dynamic Group 2, Group 4

Value	Description
0	Derating uses +1
1	Derating uses +2

Bit 0 – DERATE_ENABLE Enables derating
Present only in designs configured to support LPDDR2/LPDDR3.
This field must be set to '0' for non-LPDDR2/LPDDR3 mode.
Programming mode: Dynamic

Value	Description
0	Timing parameter derating is disabled.
1	Timing parameter derating is enabled using MR4 read value.

17.6.7 UDDRC Temperature Derate Interval Register

Name: UDDRC_DERATEINT
Offset: 0x024
Reset: 0x00800000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
	MR4_READ_INTERVAL[31:24]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	MR4_READ_INTERVAL[23:16]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	1	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	MR4_READ_INTERVAL[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	MR4_READ_INTERVAL[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 31:0 – MR4_READ_INTERVAL[31:0] Interval between two MR4 reads
Used to derate the timing parameters.
Present only in designs configured to support LPDDR2/LPDDR3. This register must not be set to zero.
Unit: DFI clock cycles.
Programming mode: Static

17.6.8 UDDRC Temperature Derate Control Register

Name: UDDRC_DERATECTL
Offset: 0x02C
Reset: 0x00000001
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
						DERATE_TEMP_LIMIT_INTR_FORCE	DERATE_TEMP_LIMIT_INTR_CLR	DERATE_TEMP_LIMIT_INTR_EN
Access						R/W	R/W	R/W
Reset						0	0	1

Bit 2 – DERATE_TEMP_LIMIT_INTR_FORCE Interrupt force bit for derate_temp_limit_intr
Setting this register to 1 will cause the derate_temp_limit_intr output pin to be asserted.
At the end of the interrupt force operation, the UDDRC automatically clears this bit.
Programming mode: Dynamic

Bit 1 – DERATE_TEMP_LIMIT_INTR_CLR Interrupt clear bit for derate_temp_limit_intr
At the end of the interrupt clear operation, the UDDRC automatically clears this bit.
Programming mode: Dynamic

Bit 0 – DERATE_TEMP_LIMIT_INTR_EN Interrupt enable bit for derate_temp_limit_intr output pin
Programming mode: Dynamic

Value	Description
0	Enabled
1	Disabled

17.6.9 UDDRC Low Power Control Register

Name: UDDRC_PWRCTL
Offset: 0x030
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
	DIS_CAM_DRAIN_SELFREF		SELFREF_SW		EN_DFI_DRAM_CLK_DISABLE	DEEPPOWERDOWN_EN	POWERDOWN_EN	SELFREF_EN
Access	R/W		R/W		R/W	R/W	R/W	R/W
Reset	0		0		0	0	0	0

Bit 7 – DIS_CAM_DRAIN_SELFREF
Indicates whether skipping CAM draining is allowed when entering Self-refresh.
This register field cannot be modified while PWRCTL.selfref_sw=1.
Note: PWRCTL.dis_cam_drain_selfref=1 is unsupported in this release. PWRCTL.dis_cam_drain_selfref=0 is required.
Programming mode: Dynamic

Value	Description
0	CAMs must be empty before entering SR.
1	CAMs are not emptied before entering SR (unsupported).

Bit 5 – SELFREF_SW
A value of 1 to this register causes system to move to Self-refresh state immediately, as long as it is not in Init or DPD/MPSM operating_mode. This is referred to as software entry/exit to Self-refresh.
Programming mode: Dynamic

Value	Description
0	Software entry to Self-refresh
1	Software exit from Self-refresh

Bit 3 – EN_DFI_DRAM_CLK_DISABLE
Enable the assertion of dfi_dram_clk_disable whenever a clock is not required by the SDRAM.
If set to 0, dfi_dram_clk_disable is never asserted.
Assertion of dfi_dram_clk_disable is as follows:

- In DDR2/DDR3, can only be asserted in Self-refresh.
- In LPDDR2/LPDDR3, can be asserted in the following cases:
  - in Self-refresh
  - in Power-down
  - in Deep Power-down

– during normal operation (clock stop)

Programming mode: Dynamic

Bit 2 – DEEPPOWERDOWN_EN
When this is 1, UDDRC puts the SDRAM into Deep Power-down mode when the transaction store is empty.
This register must be reset to '0' to bring UDDRC out of Deep Power-down mode. Controller performs automatic SDRAM initialization on deep power-down exit.
Present only in designs configured to support LPDDR2 or LPDDR3. For non-LPDDR2/non-LPDDR3, this register should not be set to 1.
For performance only.
Programming mode: Dynamic

Bit 1 – POWERDOWN_EN
If true then the UDDRC goes into Power-down after a programmable number of cycles "maximum idle clocks before power down" (PWRTMG.powerdown_to_x32).
This register bit may be re-programmed during the course of normal operation.
Programming mode: Dynamic

Bit 0 – SELFREF_EN
If true then the UDDRC puts the SDRAM into Self-refresh after a programmable number of cycles "maximum idle clocks before Self Refresh (PWRTMG.selfref_to_x32)". This register bit may be re-programmed during the course of normal operation.
Programming mode: Dynamic

17.6.10 UDDRC Low Power Timing Register

Name: UDDRC_PWRTMG
Offset: 0x034
Reset: 0x00402010
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								
Bit	23	22	21	20	19	18	17	16
	SELFREF_TO_X32[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	1	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8
	T_DPD_X4096[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	1	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
				POWERDOWN_TO_X32[4:0]				
Access				R/W	R/W	R/W	R/W	R/W
Reset				1	0	0	0	0

Bits 23:16 – SELFREF_TO_X32[7:0]
After this many clocks of the DDRC command channel being idle the UDDRC automatically puts the SDRAM into Self-refresh.
The DDRC command channel is considered idle when there are no HIF commands outstanding. This must be enabled in the PWRCTL.selfref_en.
For performance only.
Unit: Multiples of 32 DFI clock cycles.
Programming mode: Quasi-dynamic Group 4

Bits 15:8 – T_DPD_X4096[7:0] Minimum deep power-down time
For LPDDR2/LPDDR3, value from the JEDEC specification is 500 μs.
Present only in designs configured to support LPDDR2 or LPDDR3.
For performance only.
Unit: Multiples of 4096 DFI clock cycles.
Programming mode: Quasi-dynamic Group 4

Bits 4:0 – POWERDOWN_TO_X32[4:0]
After this many clocks of the DDRC command channel being idle the UDDRC automatically puts the SDRAM into Power-down. The DDRC command channel is considered idle when there are no HIF commands outstanding. This must be enabled in the PWRCTL.powerdown_en.
For performance only.
Unit: Multiples of 32 DFI clock cycles.
Programming mode: Quasi-dynamic Group 4

17.6.11 UDDRC Hardware Low Power Control Register

Name: UDDRC_HWLPCTL
Offset: 0x038
Reset: 0x00000003
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
					HW_LP_IDLE_X32[11:8]			
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bit	23	22	21	20	19	18	17	16
	HW_LP_IDLE_X32[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Access								
Reset								

Bit	7	6	5	4	3	2	1	0
							HW_LP_EXIT_IDLE_EN	HW_LP_EN
Access							R/W	R/W
Reset							1	1

Bits 27:16 – HW_LP_IDLE_X32[11:0] Hardware Idle Period
The cactive_ddrc output is driven low if the DDRC command channel is idle for hw_lp_idle * 32 cycles if not in Init or DPD/MPSM operating_mode. The DDRC command channel is considered idle when there are no HIF commands outstanding. The hardware idle function is disabled when hw_lp_idle_x32=0. hw_lp_idle_x32=1 is an illegal value.
For performance only.
Unit: Multiples of 32 DFI clock cycles.
Programming mode: Static

Bit 1 – HW_LP_EXIT_IDLE_EN
When this bit is programmed to 1 the cactive_in_ddrc pin of the DDRC can be used to exit from the Automatic Clock Stop, Automatic Power-down or Automatic Self-refresh modes. Note, it will not cause exit of Self-refresh that was caused by hardware low-power Interface and/or software (PWRCTL.selfref_sw).
Programming mode: Static

Bit 0 – HW_LP_EN Enable for Hardware Low Power Interface
Programming mode: Quasi-dynamic Group 2

17.6.12 UDDRC Refresh Control Register 0

Name: UDDRC_RFSHCTL0
Offset: 0x050
Reset: 0x00210000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
	REFRESH_MARGIN[3:0]							REFRESH_TO_X1_X32[4]
Access	R/W	R/W	R/W	R/W				R/W
Reset	0	0	1	0				1

Bit	15	14	13	12	11	10	9	8
	REFRESH_TO_X1_X32[3:0]						REFRESH_BURST[5:4]	
Access	R/W	R/W	R/W	R/W			R/W	R/W
Reset	0	0	0	0			0	0

Bit	7	6	5	4	3	2	1	0
	REFRESH_BURST[3:0]					PER_BANK_REFRESH		
Access	R/W	R/W	R/W	R/W		R/W		
Reset	0	0	0	0		0		

Bits 23:20 – REFRESH_MARGIN[3:0]
Threshold value in number of DFI clock cycles before the critical refresh or page timer expires. A critical refresh is to be issued before this threshold is reached. It is recommended that this not be changed from the default value, currently shown as 0x2. It must always be less than internally used t_rfc_nom/32.
Note that internally used t_rfc_nom is equal to RFSHTMG.t_rfc_nom_x1_x32 * 32 if RFSHTMG.t_rfc_nom_x1_sel=0. If RFSHTMG.t_rfc_nom_x1_sel=1 (for LPDDR2/LPDDR3 per-bank refresh only), internally used t_rfc_nom is equal to RFSHTMG.t_rfc_nom_x1_x32. Note that, in LPDDR2/LPDDR3, internally used t_rfc_nom may be divided by four if derating is enabled (DERATEEN.derate_enable=1).
Unit: Multiples of 32 DFI clock cycles.
Programming mode: Dynamic - Refresh Related

Bits 16:12 – REFRESH_TO_X1_X32[4:0]
If the refresh timer (tRFCnom, also known as tREFI) has expired at least once, then a speculative refresh may be performed. A speculative refresh is a refresh performed at a time when refresh would be useful. When the SDRAM bus is idle for a period of time determined by this RFSHCTL0.refresh_to_x1_x32 and the refresh timer has expired at least once since the last refresh, then a speculative refresh is performed. Speculative refreshes continues successively until there are no refreshes pending or until new reads or writes are issued to the UDDRC.
For performance only.
Unit: DFI clock cycles or multiples of 32 DFI clock cycles, depending on RFSHTMG.t_rfc_nom_x1_sel.
Programming mode: Dynamic - Refresh Related

Bits 9:4 – REFRESH_BURST[5:0]
The programmed value + 1 is the number of refresh timeouts that is allowed to accumulate before traffic is blocked and the refreshes are forced to execute. Closing pages to perform a refresh is a one-time penalty that must be paid for each group of refreshes. Therefore, performing refreshes in a burst reduces the per-refresh penalty of these page closings. Higher numbers for RFSHCTL.refresh_burst slightly increases utilization; lower numbers decreases the worst-case latency associated with refreshes.
For information on burst refresh feature refer to section 3.9 of DDR2 JEDEC specification - JESD79-2F.pdf.

For DDR2/3, the refresh is always per-rank and not per-bank. The rank refresh can be accumulated over 8*tREFI cycles using the burst refresh feature.
In per-bank refresh mode of LPDDR2/LPDDR3 (RFSHCTL0.per_bank_refresh = 1), 64 refreshes can be postponed.
Programming mode: Dynamic - Refresh Related

Value	Description
0	Single refresh
1	Burst-of-2 refresh
7	Burst-of-8 refresh

Bit 2 – PER_BANK_REFRESH
Per-bank refresh allows traffic to flow to other banks. Per-bank refresh is not supported by all LPDDR2 devices but should be supported by all LPDDR3 devices. Present only in designs configured to support LPDDR2/LPDDR3.
Programming mode: Static

Value	Description
0	All-bank refresh
1	Per-bank refresh

17.6.13 UDDRC Refresh Control Register 3

Name: UDDRC_RFSHCTL3
Offset: 0x060
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								
Bit	23	22	21	20	19	18	17	16
Access								
Reset								
Bit	15	14	13	12	11	10	9	8
Access								
Reset								
Bit	7	6	5	4	3	2	1	0
							REFRESH_UPDATE_LEVEL	DIS_AUTO_REFRESH
Access							R/W	R/W
Reset							0	0

Bit 1 – REFRESH_UPDATE_LEVEL
Toggle this signal (either from 0 to 1 or from 1 to 0) to indicate that the refresh register(s) have been updated.
refresh_update_level must not be toggled when the DDRC is in reset (core_ddrc_rstn = 0).
The refresh register(s) are automatically updated when exiting reset.
Programming mode: Dynamic

Bit 0 – DIS_AUTO_REFRESH
When '1', disable Auto-refresh generated by the UDDRC. When Auto-refresh is disabled, the SoC core must generate refreshes using the registers DBGCMD.rankn_refresh.
When dis_auto_refresh transitions from 0 to 1, any pending refreshes are immediately scheduled by the UDDRC.
This register field is changeable on the fly.
Programming mode: Dynamic - Refresh Related

17.6.14 UDDRC Refresh Timing Register

Name: UDDRC_RFSHTMG
Offset: 0x064
Reset: 0x0062008C
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
	T_RFC_NOM_X1_SEL				T_RFC_NOM_X1_X32[11:8]			
Access	R/W				R/W	R/W	R/W	R/W
Reset	0				0	0	0	0

Bit	23	22	21	20	19	18	17	16
	T_RFC_NOM_X1_X32[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	1	1	0	0	0	1	0

Bit	15	14	13	12	11	10	9	8
	LPDDR3_TREFBW_EN						T_RFC_MIN[9:8]	
Access	R/W						R/W	R/W
Reset	0						0	0

Bit	7	6	5	4	3	2	1	0
	T_RFC_MIN[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	1	0	0	0	1	1	0	0

Bit 31 – T_RFC_NOM_X1_SEL
Specifies whether the RFSHTMG.t_rfc_nom_x1_x32 and RFSHCTL0.refresh_to_x1_x32 register values are x1 or x32.
This applies only when per-bank refresh is enabled (RFSHCTL0.per_bank_refresh=1); if per-bank refresh is not enabled, the x32 register values are used and this register field is ignored.
Programming mode: Dynamic - Refresh Related

Value	Description
0	x32 register values are used.
1	x1 register values are used.

Bits 27:16 – T_RFC_NOM_X1_X32[11:0]
Average time interval between refreshes per rank (Specification: 7.8 μs for DDR2 and DDR3. See JEDEC specification for LPDDR2 and LPDDR3).
When the controller is operating in 1:1 mode, set this register to RoundDown(tREFI/tCK).
When the controller is operating in 1:2 mode, set this register to RoundDown(RoundDown(tREFI/tCK)/2).
In both the above cases, if RFSHTMG.t_rfc_nom_x1_sel = 0, divide the above result by 32 and round down.
For LPDDR2/LPDDR3:

- If using all-bank refreshes (RFSHCTL0.per_bank_refresh = 0), use tREFIab in the above calculations.
- If using per-bank refreshes (RFSHCTL0.per_bank_refresh = 1), use tREFIpb in the above calculations.

Note that:

- RFSHTMG.t_rfc_nom_x1_x32 must be greater than 0x1.
- If RFSHTMG.t_rfc_nom_x1_sel == 1, RFSHTMG.t_rfc_nom_x1_x32 must be greater than RFSHTMG.t_rfc_min.
- If RFSHTMG.t_rfc_nom_x1_sel == 0, RFSHTMG.t_rfc_nom_x1_x32 * 32 must be greater than RFSHTMG.t_rfc_min.
- In Fixed 1x mode: RFSHTMG.t_rfc_nom_x1_x32 must be less than or equal to 0xFFE.

Unit: DFI clock cycles or multiples of 32 DFI clock cycles, depending on RFSHTMG.t_rfc_nom_x1_sel.

Programming mode: Dynamic - Refresh Related

Bit 15 – LPDDR3_TREFBW_EN
Used only when LPDDR3 memory type is connected. Should only be changed when UDDRC is in reset. Specifies whether to use the tREFBW parameter (required by some LPDDR3 devices which comply with earlier versions of the LPDDR3 JEDEC specification) or not.
Programming mode: Static

Value	Description
0	tREFBW parameter not used.
1	tREFBW parameter used.

Bits 9:0 – T_RFC_MIN[9:0] tRFC (min): Minimum time from refresh to refresh or activate.
When the controller is operating in 1:1 mode, t_rfc_min should be set to RoundUp(tRFCmin/tCK).
When the controller is operating in 1:2 mode, t_rfc_min should be set to RoundUp(RoundUp(tRFCmin/tCK)/2).
In LPDDR2/LPDDR3 mode:

- If using all-bank refreshes, the tRFCmin value in the above equations is equal to tRFCab.
- If using per-bank refreshes, the tRFCmin value in the above equations is equal to tRFCpb.

Unit: DFI clock cycles.
Programming mode: Dynamic - Refresh Related

17.6.15 UDDRC CRC Parity Control Register 0

Name: UDDRC_CRCPARCTL0
Offset: 0x0C0
Reset: 0x00000000
Property: Read/Write

Note: Do not perform any APB access to CRCPARCTL0 within 32 pclk cycles of previous access to CRCPARCTL0, as this might lead to data loss.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
						DFI_ALERT_ERR_CNT_CLR	DFI_ALERT_ERR_INT_CLR	DFI_ALERT_ERR_INT_EN
Access						R/W	R/W	R/W
Reset						0	0	0

Bit 2 – DFI_ALERT_ERR_CNT_CLR DFI Alert Error Count Clear
Clear bit for DFI alert error counter. Asserting this bit will clear the DFI alert error counter, CRCPARSTAT.dfi_alert_err_cnt. UDDRC automatically clears this bit.
Programming mode: Dynamic

Bit 1 – DFI_ALERT_ERR_INT_CLR Interrupt Clear Bit for DFI Alert Error
If this bit is set, the alert error interrupt on CRCPARSTAT.dfi_alert_err_int will be cleared. UDDRC automatically clears this bit.
Programming mode: Dynamic

Bit 0 – DFI_ALERT_ERR_INT_EN Interrupt enable bit for DFI alert error
If this bit is set, any parity/CRC error detected on the dfi_alert_n input will result in an interrupt being set on CRCPARSTAT.dfi_alert_err_int.
Programming mode: Dynamic

17.6.16 UDDRC CRC Parity Status Register

Name: UDDRC_CRCPARSTAT
Offset: 0x0CC
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
								DFI_ALERT_ERR_INT
Access								R
Reset								0

Bit	15	14	13	12	11	10	9	8
	DFI_ALERT_ERR_CNT[15:8]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	DFI_ALERT_ERR_CNT[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit 16 – DFI_ALERT_ERR_INT DFI Alert Error Interrupt
If a parity/CRC error is detected on dfi_alert_n, and the interrupt is enabled by CRCPARCTL0.dfi_alert_err_int_en, this interrupt bit will be set. It will remain set until cleared by CRCPARCTL0.dfi_alert_err_int_clr.
Programming Mode: Static

Bits 15:0 – DFI_ALERT_ERR_CNT[15:0] DFI Alert Error Count
If a parity/CRC error is detected on dfi_alert_n, this counter be incremented. This is independent of the setting of CRCPARCTL0.dfi_alert_err_int_en. It will saturate at 0xFFFF, and can be cleared by asserting CRCPARCTL0.dfi_alert_err_cnt_clr.
Programming Mode: Static

17.6.17 UDDRC SDRAM Initialization Register 0

Name: UDDRC_INIT0
Offset: 0x0D0
Reset: 0x0002004E
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
	SKIP_DRAM_INIT[1:0]						POST_CKE_X1024[9:8]	
Access	R/W	R/W					R/W	R/W
Reset	0	0					0	0

Bit	23	22	21	20	19	18	17	16
	POST_CKE_X1024[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	1	0

Bit	15	14	13	12	11	10	9	8
					PRE_CKE_X1024[11:8]			
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bit	7	6	5	4	3	2	1	0
	PRE_CKE_X1024[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	1	0	0	1	1	1	0

Bits 31:30 – SKIP_DRAM_INIT[1:0]
If lower bit is enabled the SDRAM initialization routine is skipped. The upper bit decides what state the controller starts up in when reset is removed.
Programming mode: Quasi-dynamic Group 2

Value	Description
00	SDRAM Initialization routine is run after power-up.
01	SDRAM Initialization routine is skipped after power-up. Controller starts up in Normal mode.
11	SDRAM Initialization routine is skipped after power-up. Controller starts up in Self-refresh mode.
10	Reserved

Bits 25:16 – POST_CKE_X1024[9:0]
Cycles to wait after driving CKE high to start the SDRAM initialization sequence.
DDR2 typically requires a 400 ns delay, requiring this value to be programmed to 2 at all clock speeds.
LPDDR2/LPDDR3 typically requires this to be programmed for a delay of 200 µs.
When the controller is operating in 1:2 frequency ratio mode, program this to JEDEC spec value divided by 2, and round it up to the next integer value.
Unit: Multiples of 1024 DFI clock cycles.
Programming mode: Static

Bits 11:0 – PRE_CKE_X1024[11:0]
Cycles to wait after reset before driving CKE high to start the SDRAM initialization sequence.
DDR2 specifications typically require this to be programmed for a delay of ≥200 µs.
LPDDR2/LPDDR3: tINIT1 of 100 ns (min)
When the controller is operating in 1:2 frequency ratio mode, program this to JEDEC spec value divided by 2, and round it up to the next integer value.
For DDR3 RDIMMs, this should include the time needed to satisfy tSTAB.
Unit: Multiples of 1024 DFI clock cycles.
Programming mode: Static

17.6.18 UDDRC SDRAM Initialization Register 1

Name: UDDRC_INIT1
Offset: 0x0D4
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
								DRAM_RSTN_X1024[8]
Access								R/W
Reset								0

Bit	23	22	21	20	19	18	17	16
	DRAM_RSTN_X1024[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
					PRE_OCD_X32[3:0]			
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bits 24:16 – DRAM_RSTN_X1024[8:0]
Number of cycles to assert SDRAM reset signal during init sequence.
This is only present for designs supporting DDR3 devices. For use with a DDR PHY, this should be set to a minimum of 1.
When the controller is operating in 1:2 frequency ratio mode, program this to JEDEC spec value divided by 2, and round it up to the next integer value.
Unit: Multiples of 1024 DFI clock cycles.
Programming mode: Static

Bits 3:0 – PRE_OCD_X32[3:0]
Wait period before driving the OCD complete command to SDRAM.
There is no known specific requirement for this; it may be set to zero.
Unit: Multiples of 32 DFI clock cycles.
Programming mode: Static

17.6.19 UDDRC SDRAM Initialization Register 2

Name: UDDRC_INIT2
Offset: 0x0D8
Reset: 0x00000D05
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
	IDLE_AFTER_RESET_X32[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	1	1	0	1

Bit	7	6	5	4	3	2	1	0
					MIN_STABLE_CLOCK_X1[3:0]			
Access					R/W	R/W	R/W	R/W
Reset					0	1	0	1

Bits 15:8 – IDLE_AFTER_RESET_X32[7:0] Idle time after the reset command, tINIT4
Present only in designs configured to support LPDDR2.
When the controller is operating in 1:2 frequency ratio mode, program this to JEDEC spec value divided by 2, and round it up to the next integer value.
Unit: Multiples of 32 DFI clock cycles.
Programming mode: Static

Bits 3:0 – MIN_STABLE_CLOCK_X1[3:0] Time to wait after the first CKE high, tINIT2
Present only in designs configured to support LPDDR2/LPDDR3.
LPDDR2/LPDDR3 typically requires 5 x tCK delay.
When the controller is operating in 1:2 frequency ratio mode, program this to JEDEC spec value divided by 2, and round it up to the next integer value.
Unit: DFI clock cycles.
Programming mode: Static

17.6.20 UDDRC SDRAM Initialization Register 3

Name: UDDRC_INIT3
Offset: 0x0DC
Reset: 0x00000510
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
	MR[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	MR[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	EMR[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	1	0	1

Bit	7	6	5	4	3	2	1	0
	EMR[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	1	0	0	0	0

Bits 31:16 – MR[15:0]
DDR2: value to write to MR register. Bit 8 is for DLL and the setting here is ignored. The UDDRC sets this bit appropriately.
DDR3: value loaded into MR0 register.
LPDDR2/LPDDR3: value to write to MR1 register
Programming mode: Quasi-dynamic Group 1, Group 4

Bits 15:0 – EMR[15:0]
DDR2: Value to write to EMR register. Bits 9:7 are for OCD and the setting in this register is ignored. The UDDRC sets those bits appropriately.
DDR3: value to write to MR1 register. Set bit 7 to 0.
LPDDR2/LPDDR3: value to write to MR2 register
Programming mode: Quasi-dynamic Group 4

17.6.21 UDDRC SDRAM Initialization Register 4

Name: UDDRC_INIT4
Offset: 0x0E0
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
	EMR2[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	EMR2[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	EMR3[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 31:16 – EMR2[15:0] DDR2: Value to write to EMR2 register.
DDR3: Value to write to MR2 register
LPDDR2/LPDDR3: Value to write to MR3 register
Programming Mode: Quasi-dynamic Group 4

Bits 15:0 – EMR3[15:0] DDR2: Value to write to EMR3 register.
DDR3: Value to write to MR3 register
LPDDR2/LPDDR3: Unused
Programming Mode: Quasi-dynamic Group 2, Group 4

17.6.22 UDDRC SDRAM Initialization Register 5

Name: UDDRC_INIT5
Offset: 0x0E4
Reset: 0x00100004
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
	DEV_ZQINIT_X32[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	1	0	0	0	0

Bit	15	14	13	12	11	10	9	8
							MAX_AUTO_INIT_X1024[9:8]	
Access							R/W	R/W
Reset							0	0

Bit	7	6	5	4	3	2	1	0
	MAX_AUTO_INIT_X1024[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	1	0	0

Bits 23:16 – DEV_ZQINIT_X32[7:0] ZQ initial calibration, tZQINIT. Present only in designs configured to support DDR3 or LPDDR2/LPDDR3.
DDR3 typically requires 512 SDRAM clock cycles.
LPDDR2/LPDDR3 requires 1 µs.
When the controller is operating in 1:2 frequency ratio mode, program this to JEDEC spec value divided by 2, and round it up to the next integer value.
Unit: Multiples of 32 DFI clock cycles.
Programming Mode: Static

Bits 9:0 – MAX_AUTO_INIT_X1024[9:0] Maximum duration of the auto initialization, tINIT5. Present only in designs configured to support LPDDR2/LPDDR3.
LPDDR2/LPDDR3 typically requires 10 µs.
Unit: Multiples of 1024 DFI clock cycles.
Programming Mode: Static

17.6.23 UDDRC DIMM Control Register

Name: UDDRC_DIMMCTL
Offset: 0x0F0
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
							DIMM_ADDR_MIRR_EN	DIMM_STAGGER_CS_EN
Access							R/W	R/W
Reset							0	0

Bit 1 – DIMM_ADDR_MIRR_EN Address Mirroring Enable (for multi-rank UDIMM implementations).
Some UDIMMs implement address mirroring for odd ranks, which means that the following address, bank address and bank group bits are swapped: (A3, A4), (A5, A6), (A7, A8), (BA0, BA1). Setting this bit ensures that, for mode register accesses during the automatic initialization routine, these bits are swapped within the UDDRC to compensate for this UDIMM/RDIMM/LRDIMM swapping.
This is not supported for LPDDR2 or LPDDR3 SDRAMs.
Programming Mode: Static
Note: This has no effect on the address of any other memory accesses, or of software-driven mode register accesses.

Value	Description
0	For odd ranks, implement address mirroring for MRS commands to during initialization
1	Do not implement address mirroring

Bit 0 – DIMM_STAGGER_CS_EN Staggering enable for multi-rank accesses (for multi-rank UDIMM, RDIMM and LRDIMM implementations only). This is not supported for LPDDR2 or LPDDR3 SDRAMs.
Programming Mode: Static
Note: Even if this bit is set it does not take care of software driven MR commands (via MRCTRL0/MRCTRL1), where software is responsible to send them to separate ranks as appropriate.

Value	Description
0	Send all commands to even and odd ranks separately
1	Do not stagger accesses

17.6.24 UDDRC SDRAM Timing Register 0

Name: UDDRC_DRAMTMG0
Offset: 0x100
Reset: 0x0F101B0F
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
		WR2PRE[6:0]						
Access		R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset		0	0	0	1	1	1	1

Bit	23	22	21	20	19	18	17	16
			T_FAW[5:0]					
Access			R/W	R/W	R/W	R/W	R/W	R/W
Reset			0	1	0	0	0	0

Bit	15	14	13	12	11	10	9	8
		T_RAS_MAX[6:0]						
Access		R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset		0	0	1	1	0	1	1

Bit	7	6	5	4	3	2	1	0
			T_RAS_MIN[5:0]					
Access			R/W	R/W	R/W	R/W	R/W	R/W
Reset			0	0	1	1	1	1

Bits 30:24 – WR2PRE[6:0] Minimum time between write and precharge to same bank.
Specifications: WL + BL/2 + tWR = approximately 8 cycles + 15 ns = 14 clocks @400MHz and less for lower frequencies
where:
- WL = write latency
- BL = burst length. This must match the value programmed in the BL bit of the mode register to the SDRAM. BST (burst terminate) is not supported at present.
- tWR = Write recovery time. This comes directly from the SDRAM specification.

Add one extra cycle for LPDDR2/LPDDR3 for this parameter.
When the controller is operating in 1:2 frequency ratio mode, 1T mode, divide the above value by 2. No rounding up.
When the controller is operating in 1:2 frequency ratio mode or 2T mode, divide the above value by 2 and round it up to the next integer value.
Note that, depending on the PHY, if using LRDIMM, it may be necessary to adjust the value of this parameter to compensate for the extra cycle of latency through the LRDIMM.
Unit: DFI clock cycles.
Programming Mode: Quasi-dynamic Group 1, Group 2, Group 4

Bits 21:16 – T_FAW[5:0] tFAW: Valid only when 8 or more banks (or banks x bank groups) are present.
In 8-bank design, at most 4 banks must be activated in a rolling window of tFAW cycles.
When the controller is operating in 1:2 frequency ratio mode, program this to (tFAW/2) and round up to next integer value.
In a 4-bank design, set this register to 0x1 independent of the 1:1/1:2 frequency mode.
Unit: DFI clock cycles.
Programming Mode: Quasi-dynamic Group 2, Group 4

Bits 14:8 – T_RAS_MAX[6:0] tRAS(max): Maximum time between activate and precharge to same bank. This is the maximum time that a page can be kept open
Minimum value of this register is 1. Zero is invalid.
When the controller is operating in 1:1 frequency ratio mode, t_ras_max should be set to RoundDown(tRAS(max)/tCK/1024).

When the controller is operating in 1:2 frequency ratio mode, t_ras_max should be set to RoundDown((RoundDown(tRAS(max)/tCK/1024)-1)/2).
Unit: Multiples of 1024 DFI clock cycles.
Programming Mode: Quasi-dynamic Group 2, Group 4

Bits 5:0 – T_RAS_MIN[5:0] tRAS(min): Minimum time between activate and precharge to the same bank.
When the controller is operating in 1:2 frequency mode, 1T mode, program this to tRAS(min)/2. No rounding up.
When the controller is operating in 1:2 frequency ratio mode or 2T mode, program this to (tRAS(min)/2) and round it up to the next integer value.
Unit: DFI clock cycles.
Programming Mode: Quasi-dynamic Group 2, Group 4

17.6.25 UDDRC SDRAM Timing Register 1

Name: UDDRC_DRAMTMG1
Offset: 0x104
Reset: 0x00080414
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
				T_XP[4:0]				
Access				R/W	R/W	R/W	R/W	R/W
Reset				0	1	0	0	0

Bit	15	14	13	12	11	10	9	8
			RD2PRE[5:0]					
Access			R/W	R/W	R/W	R/W	R/W	R/W
Reset			0	0	0	1	0	0

Bit	7	6	5	4	3	2	1	0
		T_RC[6:0]						
Access		R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset		0	0	1	0	1	0	0

Bits 20:16 – T_XP[4:0] tXP: Minimum time after power-down exit to any operation. For DDR3, this should be programmed to tXPDLL if slow powerdown exit is selected in MR0[12].
When the controller is operating in 1:2 frequency ratio mode, program this to (tXP/2) and round it up to the next integer value.
Units: DFI clock cycles.
Programming Mode: Quasi-dynamic Group 2, Group 4

Bits 13:8 – RD2PRE[5:0] tRTP: Minimum time from read to precharge of same bank.
- DDR2: tAL + BL/2 + max(tRTP, 2) - 2
- DDR3: tAL + max (tRTP, 4)
- LPDDR2: Depends on if it's LPDDR2-S2 or LPDDR2-S4:
LPDDR2-S2: BL/2 + tRTP - 1.
LPDDR2-S4: BL/2 + max(tRTP,2) - 2.
- LPDDR3: BL/2 + max(tRTP,4) - 4
When the controller is operating in 1:2 mode, 1T mode, divide the above value by 2. No rounding up.
When the controller is operating in 1:2 mode or 2T mode, divide the above value by 2 and round it up to the next integer value.
Unit: DFI clock cycles.
Programming Mode: Quasi-dynamic Group 1, Group 2, Group 4

Bits 6:0 – T_RC[6:0] tRC: Minimum time between activates to same bank.
When the controller is operating in 1:2 frequency ratio mode, program this to (tRC/2) and round up to next integer value.
Unit: DFI clock cycles.
Programming Mode: Quasi-dynamic Group 2, Group 4

17.6.26 UDDRC SDRAM Timing Register 2

Name: UDDRC_DRAMTMG2
Offset: 0x108
Reset: 0x0305060D
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
			WRITE_LATENCY[5:0]					
Access			R/W	R/W	R/W	R/W	R/W	R/W
Reset			0	0	0	0	1	1

Bit	23	22	21	20	19	18	17	16
			READ_LATENCY[5:0]					
Access			R/W	R/W	R/W	R/W	R/W	R/W
Reset			0	0	0	1	0	1

Bit	15	14	13	12	11	10	9	8
			RD2WR[5:0]					
Access			R/W	R/W	R/W	R/W	R/W	R/W
Reset			0	0	0	1	1	0

Bit	7	6	5	4	3	2	1	0
			WR2RD[5:0]					
Access			R/W	R/W	R/W	R/W	R/W	R/W
Reset			0	0	1	1	0	1

Bits 29:24 – WRITE_LATENCY[5:0] Set to WL
Time from write command to write data on SDRAM interface. This must be set to WL.
Note that, depending on the PHY, if using RDIMM/LRDIMM, it may be necessary to adjust the value of WL to compensate for the extra cycle of latency through the RDIMM/LRDIMM.
When the controller is operating in 1:2 frequency ratio mode, divide the value calculated using the above equation by 2, and round it up to next integer.
This register field is not required for DDR2 and DDR3, as the DFI read and write latencies defined in DFITMG0 and DFITMG1 are sufficient for those protocols
For all protocols, in addition to programming this register field, it is necessary to program DFITMG0 and DFITMG1 to control the read and write latencies
Unit: DFI clock cycles.
Programming Mode: Quasi-dynamic Group 1, Group 2, Group 4

Bits 21:16 – READ_LATENCY[5:0] Set to RL
Time from read command to read data on SDRAM interface. This must be set to RL.
Note that, depending on the PHY, if using RDIMM/LRDIMM, it may be necessary to adjust the value of RL to compensate for the extra cycle of latency through the RDIMM/LRDIMM.
When the controller is operating in 1:2 frequency ratio mode, divide the value calculated using the above equation by 2, and round it up to next integer.
This register field is not required for DDR2 and DDR3, as the DFI read and write latencies defined in DFITMG0 and DFITMG1 are sufficient for those protocols
For all protocols, in addition to programming this register field, it is necessary to program DFITMG0 and DFITMG1 to control the read and write latencies
Unit: DFI clock cycles.
Programming Mode: Quasi-dynamic Group 1, Group 2, Group 4

Bits 13:8 – RD2WR[5:0]
DDR2/3: RL + BL/2 + 2 - WL
LPDDR2/LPDDR3: RL + BL/2 + RU(tDQSCKmax/tCK) + 1 - WL

Minimum time from read command to write command. Include time for bus turnaround and all per-bank, per-rank, and global constraints.
Please see the relevant PHY databook for details of what should be included here.
Where:
- WL = write latency
- BL = burst length. This must match the value programmed in the BL bit of the mode register to the SDRAM
- RL = read latency = CAS latency
After PHY has completed training the value programmed may need to be increased. Refer to relevant PHY documentation.
For LPDDR2/LPDDR3, if derating is enabled (DERATEEN.derate_enable=1), derated tDQSCKmax should be used.
When the controller is operating in 1:2 frequency ratio mode, divide the value calculated using the above equation by 2, and round it up to next integer.
Note that, depending on the PHY, if using LRDIMM, it may be necessary to adjust the value of this parameter to compensate for the extra cycle of latency through the LRDIMM.
Unit: DFI clock cycles.
Programming Mode: Quasi-dynamic Group 1, Group 2, Group 4

Bits 5:0 – WR2RD[5:0]
LPDDR2/3: WL + BL/2 + tWTR + 1
Others: CWL + BL/2 + tWTR
Please see the relevant PHY databook for details of what should be included here.
Where:
- CWL = CAS write latency
- WL = Write latency
- PL = Parity latency
- BL = burst length. This must match the value programmed in the BL bit of the mode register to the SDRAM
- tWTR_L = internal write to read command delay for same bank group. This comes directly from the SDRAM specification.
- tWTR = internal write to read command delay. This comes directly from the SDRAM specification.
After PHY has completed training the value programmed may need to be increased. Refer to relevant PHY documentation.
Add one extra cycle for LPDDR2/LPDDR3 operation.
When the controller is operating in 1:2 mode, divide the value calculated using the above equation by 2, and round it up to next integer.
Unit: DFI clock cycles.
Programming Mode: Quasi-dynamic Group 1, Group 2, Group 4

17.6.27 UDDRC SDRAM Timing Register 3

Name: UDDRC_DRAMTMG3
Offset: 0x10C
Reset: 0x0050400C
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
			T_MRW[9:4]					
Access			R/W	R/W	R/W	R/W	R/W	R/W
Reset			0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	T_MRW[3:0]						T_MRD[5:4]	
Access	R/W	R/W	R/W	R/W			R/W	R/W
Reset	0	1	0	1			0	0

Bit	15	14	13	12	11	10	9	8
	T_MRD[3:0]						T_MOD[9:8]	
Access	R/W	R/W	R/W	R/W			R/W	R/W
Reset	0	1	0	0			0	0

Bit	7	6	5	4	3	2	1	0
	T_MOD[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	1	1	0	0

Bits 29:20 – T_MRW[9:0] Time to wait after a mode register write or read (MRW or MRR).
Present only in designs configured to support LPDDR2 or LPDDR3.
LPDDR2 typically requires value of 5.
LPDDR3 typically requires value of 10.
For LPDDR2, this register is used for the time from a MRW/MRR to all other commands.
When the controller is operating in 1:2 frequency ratio mode, program this to the above values divided by 2 and round it up to the next integer value.
For LDPDR3, this register is used for the time from a MRW/MRR to a MRW/MRR.
Unit: DFI clock cycles.
Programming Mode: Quasi-dynamic Group 2, Group 4

Bits 17:12 – T_MRD[5:0] tMRD: Cycles to wait after a mode register write or read. Depending on the connected SDRAM, tMRD represents:
DDR2: Time from MRS to any command
DDR3: Time from MRS to MRS command
LPDDR2: not used
LPDDR3: Time from MRS to non-MRS command.
When the controller is operating in 1:2 frequency ratio mode, program this to (tMRD/2) and round it up to the next integer value.
If CAL mode is enabled (DFITMG1.dfi_t_cmd_lat > 0), tCAL (=DFITMG1.dfi_cmd_lat) should be added to the above calculations.
Unit: DFI clock cycles.
Programming Mode: Quasi-dynamic Group 2, Group 4

Bits 9:0 – T_MOD[9:0] tMOD: Parameter used only in DDR3. Cycles between load mode command and following non-load mode command.
If CAL mode is enabled (DFITMG1.dfi_t_cmd_lat > 0), tCAL (=DFITMG1.dfi_cmd_lat) should be added to the above calculations.
Set to tMOD if controller is operating in 1:1 frequency ratio mode, or tMOD/2 (rounded up to next integer) if controller is operating in 1:2 frequency ratio mode. Note that if using RDIMM/LRDIMM, depending on the PHY, it may be

necessary to adjust the value of this parameter to compensate for the extra cycle of latency applied to mode register writes by the RDIMM/LRDIMM chip.
Also note that if using LRDIMM, the minimum value of this register is tMRD_L2 if controller is operating in 1:1 frequency ratio mode, or tMRD_L2/2 (rounded up to next integer) if controller is operating in 1:2 frequency ratio mode.
Unit: DFI clock cycles.
Programming Mode: Quasi-dynamic Group 2, Group 4

17.6.28 UDDRC SDRAM Timing Register 4

Name: UDDRC_DRAMTMG4
Offset: 0x110
Reset: 0x05040405
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
				T_RCD[4:0]				
Access				R/W	R/W	R/W	R/W	R/W
Reset				0	0	1	0	1

					T_RRD[3:0]			
Access					R/W	R/W	R/W	R/W
Reset					0	1	0	0

Bit	7	6	5	4	3	2	1	0
				T_RP[4:0]				
Access				R/W	R/W	R/W	R/W	R/W
Reset				0	0	1	0	1

Bits 28:24 – T_RCD[4:0] tRCD - tAL: Minimum time from activate to read or write command to same bank.
When the controller is operating in 1:2 frequency ratio mode, program this to ((tRCD - tAL)/2) and round it up to the next integer value.
Minimum value allowed for this register is 1, which implies minimum (tRCD - tAL) value to be 2 when the controller is operating in 1:2 frequency ratio mode.
Unit: DFI clock cycles.
Programming Mode: Quasi-dynamic Group 1, Group 2, Group 4

Bits 19:16 – T_CCD[3:0] tCCD: This is the minimum time between two reads or two writes
When the controller is operating in 1:2 frequency ratio mode, program this to (tCCD_L/2 or tCCD/2) and round it up to the next integer value.
Unit: DFI clock cycles.
Programming Mode: Quasi-dynamic Group 2, Group 4

Bits 11:8 – T_RRD[3:0] tRRD: Minimum time between activates from bank "a" to bank "b"
When the controller is operating in 1:2 frequency ratio mode, program this to (tRRD_L/2 or tRRD/2) and round it up to the next integer value.
Unit: DFI clock cycles.
Programming Mode: Quasi-dynamic Group 2, Group 4

Bits 4:0 – T_RP[4:0] tRP: Minimum time from single-bank precharge to activate of same bank.
When the controller is operating in 1:1 frequency ratio mode, t_rp should be set to RoundUp(tRP/tCK).
When the controller is operating in 1:2 frequency ratio mode, t_rp should be set to RoundDown(RoundUp(tRP/tCK)/2) + 1.
Unit: DFI clock cycles.
Programming Mode: Quasi-dynamic Group 2, Group 4

17.6.29 UDDRC SDRAM Timing Register 5

Name: UDDRC_DRAMTMG5
Offset: 0x114
Reset: 0x05050403
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
					T_CKSRX[3:0]			
Access					R/W	R/W	R/W	R/W
Reset					0	1	0	1

					T_CKSRE[3:0]			
Access					R/W	R/W	R/W	R/W
Reset					0	1	0	1

Bit	15	14	13	12	11	10	9	8
			T_CKESR[5:0]					
Access			R/W	R/W	R/W	R/W	R/W	R/W
Reset			0	0	0	1	0	0

Bit	7	6	5	4	3	2	1	0
				T_CKE[4:0]				
Access				R/W	R/W	R/W	R/W	R/W
Reset				0	0	0	1	1

Bits 27:24 – T_CKSRX[3:0] This is the time before Self Refresh Exit that CK is maintained as a valid clock before issuing SRX. Specifies the clock stable time before SRX.
Recommended settings:
- LPDDR2: 2
- LPDDR3: 2
- DDR2: 1
- DDR3: tCKSRX
When the controller is operating in 1:2 frequency ratio mode, program this to recommended value divided by two and round it up to next integer.
Unit: DFI clock cycles.
Programming Mode: Quasi-dynamic Group 2, Group 4

Bits 19:16 – T_CKSRE[3:0] This is the time after Self Refresh Down Entry that CK is maintained as a valid clock. Specifies the clock disable delay after SRE.
Recommended settings:
- LPDDR2: 2
- LPDDR3: 2
- DDR2: 1
- DDR3: max (10 ns, 5 tCK)
Unit: DFI clock cycles.
Programming Mode: Quasi-dynamic Group 2, Group 4

Bits 13:8 – T_CKESR[5:0] Minimum CKE low width for Self refresh or Self refresh power down entry to exit timing in memory clock cycles.
Recommended settings:
- LPDDR2: tCKESR
- LPDDR3: tCKESR
- DDR2: tCKE
- DDR3: tCKE + 1
Unit: DFI clock cycles.

Programming Mode: Quasi-dynamic Group 2, Group 4

Bits 4:0 – T_CKE[4:0] Minimum number of cycles of CKE HIGH/LOW during power-down and self refresh.
- LPDDR2/LPDDR3 mode: Set this to the larger of tCKE or tCKESR
- Non-LPDDR2/non-LPDDR3 designs: Set this to tCKE value.
When the controller is operating in 1:2 frequency ratio mode, program this to (value described above)/2 and round it up to the next integer value.
Unit: DFI clock cycles.
Programming Mode: Quasi-dynamic Group 2, Group 4

17.6.30 UDDRC SDRAM Timing Register 6

Name: UDDRC_DRAMTMG6
Offset: 0x118
Reset: 0x02020005
Property: Read/Write

Bits 27:24 – T_CKDPDE[3:0] This is the time after Deep Power Down Entry that CK is maintained as a valid clock. Specifies the clock disable delay after DPDE.
Recommended settings:
- LPDDR2: 2
- LPDDR3: 2
When the controller is operating in 1:2 frequency ratio mode, program this to recommended value divided by two and round it up to next integer.
This is only present for designs supporting LPDDR2/LPDDR3 devices.
Unit: DFI clock cycles.
Programming Mode: Quasi-dynamic Group 2, Group 4

Bits 19:16 – T_CKDPDX[3:0] This is the time before Deep Power Down Exit that CK is maintained as a valid clock before issuing DPDX. Specifies the clock stable time before DPDX.
Recommended settings:
- LPDDR2: 2
- LPDDR3: 2
When the controller is operating in 1:2 frequency ratio mode, program this to recommended value divided by two and round it up to next integer.
This is only present for designs supporting LPDDR2 devices.
Unit: DFI clock cycles.
Programming Mode: Quasi-dynamic Group 2, Group 4

Bits 3:0 – T_CKCSX[3:0] This is the time before Clock Stop Exit that CK is maintained as a valid clock before issuing Clock Stop Exit. Specifies the clock stable time before next command after Clock Stop Exit.
Recommended settings:
- LPDDR2: tXP + 2
- LPDDR3: tXP + 2
When the controller is operating in 1:2 frequency ratio mode, program this to recommended value divided by two and round it up to next integer.
This is only present for designs supporting LPDDR2/LPDDR3 devices.

Unit: DFI clock cycles.
Programming Mode: Quasi-dynamic Group 2, Group 4

17.6.31 UDDRC SDRAM Timing Register 7

Name: UDDRC_DRAMTMG7
Offset: 0x11C
Reset: 0x00000202
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access

Access					R/W	R/W	R/W	R/W
Reset					0	0	1	0

Bits 11:8 – T_CKPDE[3:0] This is the time after Power Down Entry that CK is maintained as a valid clock. Specifies the clock disable delay after PDE.
Recommended settings:
- LPDDR2: 2
- LPDDR3: 2

When using DDR2/3 SDRAM, this register should be set to the same value as DRAMTMG5.t_cksre.
When the controller is operating in 1:2 frequency ratio mode, program this to recommended value divided by two and round it up to next integer.
This is only present for designs supporting LPDDR2/LPDDR3 devices.
Unit: DFI clock cycles.
Programming Mode: Quasi-dynamic Group 2, Group 4

Bits 3:0 – T_CKPDX[3:0] This is the time before Power Down Exit that CK is maintained as a valid clock before issuing PDX. Specifies the clock stable time before PDX.
Recommended settings:
- LPDDR2: 2
- LPDDR3: 2

When using DDR2/3 SDRAM, this register should be set to the same value as DRAMTMG5.t_cksrx.
When the controller is operating in 1:2 frequency ratio mode, program this to recommended value divided by two and round it up to next integer.
This is only present for designs supporting LPDDR2/LPDDR3 devices.
Unit: DFI clock cycles.
Programming Mode: Quasi-dynamic Group 2, Group 4

17.6.32 UDDRC SDRAM Timing Register 8

Name: UDDRC_DRAMTMG8

Bit	7	6	5	4	3	2	1	0
		T_XS_X32[6:0]						
Access		R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset		0	0	0	0	1	0	1

Bits 14:8 – T_XS_DLL_X32[6:0] tXSDLL: Exit Self Refresh to commands requiring a locked DLL.
When the controller is operating in 1:2 frequency ratio mode, program this to the above value divided by 2 and round up to next integer value.
Unit: Multiples of 32 DFI clock cycles.
Programming Mode: Quasi-dynamic Group 2, Group 4
Note: Used only for DDR2 and DDR3 SDRAMs.

Bits 6:0 – T_XS_X32[6:0] tXS: Exit Self Refresh to commands not requiring a locked DLL.
When the controller is operating in 1:2 frequency ratio mode, program this to the above value divided by 2 and round up to next integer value.
Unit: Multiples of 32 DFI clock cycles.
Programming Mode: Quasi-dynamic Group 2, Group 4
Note: Used only for DDR2 and DDR3 SDRAMs.

17.6.33 UDDRC SDRAM Timing Register 14

Name: UDDRC_DRAMTMG14
Offset: 0x138
Reset: 0x000000A0
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	1	0	1	0	0	0	0	0

Bits 11:0 – T_XSR[11:0] tXSR: Exit Self Refresh to any command.
When the controller is operating in 1:2 frequency ratio mode, program this to the above value divided by 2 and round up to next integer value.
The value 0xfff is illegal for this register field.
Unit: DFI clock cycles.
Programming Mode: Quasi-dynamic Group 2, Group 4
Note: Used only for LPDDR2/LPDDR3 mode.

17.6.34 UDDRC SDRAM Timing Register 15

Name: UDDRC_DRAMTMG15
Offset: 0x13C
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
	EN_DFI_LP_T_STAB							
Access	R/W							
Reset	0							

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access

Bit	7	6	5	4	3	2	1	0
	T_STAB_X32[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit 31 – EN_DFI_LP_T_STAB
Programming Mode: Quasi-dynamic Group 2, Group 4

Value	Description
0	Disable using tSTAB when exiting DFI LP.
1	Enable using tSTAB when exiting DFI LP. Needs to be set when the PHY is stopping the clock during DFI LP to save maximum power.

Bits 7:0 – T_STAB_X32[7:0] tSTAB: Stabilization time.
It is required in the following two cases for DDR3 RDIMM:

- when exiting power saving mode, if the clock was stopped, after re-enabling it the clock must be stable for a time specified by tSTAB
- after issuing control words that refers to clock timing

(Specification: 6 μs for DDR3)
When the controller is operating in 1:2 frequency ratio mode, program this to recommended value divided by two and round it up to next integer.
Unit: Multiples of 32 DFI clock cycles.
Programming Mode: Quasi-dynamic Group 2, Group 4

17.6.35 UDDRC ZQ Control Register 0

Name: UDDRC_ZQCTL0
Offset: 0x180
Reset: 0x02000040
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
	DIS_AUTO_ZQ	DIS_SRX_ZQCL	ZQ_RESISTOR_SHARED			T_ZQ_LONG_NOP[10:8]		
Access	R/W	R/W	R/W			R/W	R/W	R/W
Reset	0	0	0			0	1	0

Bit	23	22	21	20	19	18	17	16

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
							T_ZQ_SHORT_NOP[9:8]	
Access							R/W	R/W
Reset							0	0

Bit	7	6	5	4	3	2	1	0
	T_ZQ_SHORT_NOP[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	1	0	0	0	0	0	0

Bit 31 – DIS_AUTO_ZQ
This is only present for designs supporting DDR3 or LPDDR2/LPDDR3 devices.
Programming Mode: Dynamic

Value	Description
0	Internally generate ZQCS/MPC(ZQ calibration) commands based on ZQCTL1.t_zq_short_interval_x1024.
1	Disable UDDRC generation of ZQCS/MPC(ZQ calibration) command. Register DBGCMD.zq_calib_short can be used instead to issue ZQ calibration request from APB module.

Bit 30 – DIS_SRX_ZQCL
This is only present for designs supporting DDR3 or LPDDR2/LPDDR3 devices.
Programming Mode: Quasi-dynamic Group 2, Group 4

Value	Description
0	Enable issuing of ZQCL/MPC(ZQ calibration) command at Self-Refresh/SR-Powerdown exit. Only applicable when run in DDR3, LPDDR2 or LPDDR3 mode.
1	Disable issuing of ZQCL/MPC(ZQ calibration) command at Self-Refresh/SR-Powerdown exit. Only applicable when run in DDR3, LPDDR2 or LPDDR3 mode.

Bit 29 – ZQ_RESISTOR_SHARED
This is only present for designs supporting DDR3 or LPDDR2/LPDDR3 devices.
Programming Mode: Static

Value	Description
0	ZQ resistor is not shared.
1	Denotes that ZQ resistor is shared between ranks. Means ZQinit/ZQCL/ZQCS/MPC(ZQ calibration) commands are sent to one rank at a time with tZQinit/tZQCL/tZQCS/tZQCAL/tZQLAT timing met between commands so that commands to different ranks do not overlap.

Bits 26:16 – T_ZQ_LONG_NOP[10:0] tZQoper for DDR3, tZQCL for LPDDR2/LPDDR3: Number of DFI clock cycles of NOP required after a ZQCL (ZQ calibration long)/MPC(ZQ Start) command is issued to SDRAM.
When the controller is operating in 1:2 frequency ratio mode:
DDR3: program this to tZQoper/2 and round it up to the next integer value.
LPDDR2/LPDDR3: program this to tZQCL/2 and round it up to the next integer value.
This is only present for designs supporting DDR3 or LPDDR2/LPDDR3 devices.
Unit: DFI clock cycles.
Programming Mode: Static

Bits 9:0 – T_ZQ_SHORT_NOP[9:0] tZQCS for DDR3/DD4/LPDDR2/LPDDR3: Number of DFI clock cycles of NOP required after a ZQCS (ZQ calibration short)/MPC(ZQ Latch) command is issued to SDRAM.
When the controller is operating in 1:2 frequency ratio mode, program this to tZQCS/2 and round it up to the next integer value.
This is only present for designs supporting DDR3 or LPDDR2/LPDDR3 devices.
Unit: DFI clock cycles.
Programming Mode: Static

17.6.36 UDDRC ZQ Control Register 1

Name: UDDRC_ZQCTL1
Offset: 0x184
Reset: 0x02000100
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
			T_ZQ_RESET_NOP[9:4]					
Access			R/W	R/W	R/W	R/W	R/W	R/W

	T_ZQ_RESET_NOP[3:0]				T_ZQ_SHORT_INTERVAL_X1024[19:16]			
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	T_ZQ_SHORT_INTERVAL_X1024[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	1

Bit	7	6	5	4	3	2	1	0
	T_ZQ_SHORT_INTERVAL_X1024[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 29:20 – T_ZQ_RESET_NOP[9:0] tZQReset: Number of DFI clock cycles of NOP required after a ZQReset (ZQ calibration Reset) command is issued to SDRAM.
When the controller is operating in 1:2 frequency ratio mode, program this to tZQReset/2 and round it up to the next integer value.
This is only present for designs supporting LPDDR2/LPDDR3 devices.
Unit: DFI clock cycles.
Programming Mode: Static

Bits 19:0 – T_ZQ_SHORT_INTERVAL_X1024[19:0] Average interval to wait between automatically issuing ZQCS (ZQ calibration short)/MPC(ZQ calibration) commands to DDR3/LPDDR2/LPDDR3 devices.
Meaningless, if ZQCTL0.dis_auto_zq=1.
This is only present for designs supporting DDR3 or LPDDR2/LPDDR3 devices.
Unit: Multiples of 1024 DFI clock cycles.
Programming Mode: Static

17.6.37 UDDRC ZQ Control Register 2

Name: UDDRC_ZQCTL2
Offset: 0x188
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
								ZQ_RESET
Access								R/W
Reset								0

Bit 0 – ZQ_RESET
Setting this register bit to 1 triggers a ZQ Reset operation. When the ZQ Reset operation is complete, the UDDRC automatically clears this bit. It is recommended NOT to set this register bit if in Init, in Self-Refresh or Deep power-down operating modes.
For Self-Refresh or SR-Powerdown it will be scheduled after SR has been exited.
For Deep power down, it will not be scheduled, although ZQSTAT.zq_reset_busy will be de-asserted.
This is only present for designs supporting LPDDR2/LPDDR3 devices.
Programming Mode: Dynamic

17.6.38 UDDRC ZQ Status Register

Name: UDDRC_ZQSTAT
Offset: 0x18C
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
								ZQ_RESET_BUSY
Access								R
Reset								0

Bit 0 – ZQ_RESET_BUSY SoC core may initiate a ZQ Reset operation only if this signal is low. This signal goes high in the clock after the UDDRC accepts the ZQ Reset request. It goes low when the ZQ Reset command is issued to the SDRAM and the associated NOP period is over. It is recommended not to perform ZQ Reset commands when this signal is high.
Programming Mode: Dynamic

Value	Description
0	Indicates that the SoC core can initiate a ZQ Reset operation.
1	Indicates that ZQ Reset operation is in progress.

17.6.39 UDDRC DFI Timing Register 0

Name: UDDRC_DFITMG0
Offset: 0x190
Reset: 0x07020002
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
				DFI_T_CTRL_DELAY[4:0]				
Access				R/W	R/W	R/W	R/W	R/W
Reset				0	0	1	1	1

Bit	23	22	21	20	19	18	17	16
	DFI_RDDATA_USE_DFI_PHY_CLK	DFI_T_RDDATA_EN[6:0]						
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	1	0

Bit	15	14	13	12	11	10	9	8
	DFI_WRDATA_USE_DFI_PHY_CLK		DFI_TPHY_WRDATA[5:0]					
Access	R/W		R/W	R/W	R/W	R/W	R/W	R/W
Reset	0		0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
			DFI_TPHY_WRLAT[5:0]					
Access			R/W	R/W	R/W	R/W	R/W	R/W
Reset			0	0	0	0	1	0

Bits 28:24 – DFI_T_CTRL_DELAY[4:0] Specifies the number of DFI clock cycles after an assertion or de-assertion of the DFI control signals that the control signals at the PHY-DRAM interface reflect the assertion or de-assertion. If the DFI clock and the memory clock are not phase-aligned, this timing parameter should be rounded up to the next integer value. Note that if using RDIMM/LRDIMM, it is necessary to increment this parameter by RDIMM's/LRDIMM's extra cycle of latency in terms of DFI clock.
Unit: DFI clock cycles.
Programming Mode: Quasi-dynamic Group 4

Bit 23 – DFI_RDDATA_USE_DFI_PHY_CLK Defines whether dfi_rddata_en/dfi_rddata/dfi_rddata_valid is generated using HDR (DFI clock) or SDR (DFI PHY clock) values.
Selects whether value in DFITMG0.dfi_t_rddata_en is in terms of HDR (DFI clock) or SDR (DFI PHY clock) cycles:
- 0 in terms of HDR (DFI clock) cycles
- 1 in terms of SDR (DFI PHY clock) cycles
Refer to PHY specification for correct value.
Programming Mode: Static

Bits 22:16 – DFI_T_RDDATA_EN[6:0] Time from the assertion of a read command on the DFI interface to the assertion of the dfi_rddata_en signal.
Refer to PHY specification for correct value.
This corresponds to the DFI parameter trddata_en. Note that, depending on the PHY, if using RDIMM/LRDIMM, it may be necessary to use the adjusted value of CL in the calculation of trddata_en. This is to compensate for the extra cycle(s) of latency through the RDIMM/LRDIMM.
Unit: DFI clock cycles or DFI PHY clock cycles, depending on DFITMG0.dfi_rddata_use_dfi_phy_clk.
Programming Mode: Quasi-dynamic Group 1, Group 4

Bit 15 – DFI_WRDATA_USE_DFI_PHY_CLK Defines whether dfi_wrdata_en/dfi_wrdata/dfi_wrdata_mask is generated using HDR (DFI clock) or SDR (DFI PHY clock) values
Selects whether value in DFITMG0.dfi_tphy_wrlat is in terms of HDR (DFI clock) or SDR (DFI PHY clock) cycles
Selects whether value in DFITMG0.dfi_tphy_wrdata is in terms of HDR (DFI clock) or SDR (DFI PHY clock) cycles
- 0 in terms of HDR (DFI clock) cycles
- 1 in terms of SDR (DFI PHY clock) cycles
Refer to PHY specification for correct value.
Programming Mode: Static

Bits 13:8 – DFI_TPHY_WRDATA[5:0] Specifies the number of clock cycles between when dfi_wrdata_en is asserted to when the associated write data is driven on the dfi_wrdata signal. This corresponds to the DFI timing parameter tphy_wrdata. Refer to PHY specification for correct value. Note, max supported value is 8.
Unit: DFI clock cycles or DFI PHY clock cycles, depending on DFITMG0.dfi_wrdata_use_dfi_phy_clk.
Programming Mode: Quasi-dynamic Group 4

Bits 5:0 – DFI_TPHY_WRLAT[5:0] Write latency
Number of clocks from the write command to write data enable (dfi_wrdata_en). This corresponds to the DFI timing parameter tphy_wrlat.
Refer to PHY specification for correct value. Note that, depending on the PHY, if using RDIMM/LRDIMM, it may be necessary to use the adjusted value of CL in the calculation of tphy_wrlat. This is to compensate for the extra cycle(s) of latency through the RDIMM/LRDIMM.
Unit: DFI clock cycles or DFI PHY clock cycles, depending on DFITMG0.dfi_wrdata_use_dfi_phy_clk.
Programming Mode: Quasi-dynamic Group 1, Group 4

17.6.40 UDDRC DFI Timing Register 1

Name: UDDRC_DFITMG1
Offset: 0x194
Reset: 0x00000404
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
							DFI_T_PARIN_LAT[1:0]	
Access							R/W	R/W
Reset							0	0

Bit	23	22	21	20	19	18	17	16
				DFI_T_WRDATA_DELAY[4:0]				
Access				R/W	R/W	R/W	R/W	R/W
Reset				0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
				DFI_T_DRAM_CLK_DISABLE[4:0]				
Access				R/W	R/W	R/W	R/W	R/W
Reset				0	0	1	0	0

Bit	7	6	5	4	3	2	1	0
				DFI_T_DRAM_CLK_ENABLE[4:0]				
Access				R/W	R/W	R/W	R/W	R/W
Reset				0	0	1	0	0

Bits 25:24 – DFI_T_PARIN_LAT[1:0] Specifies the number of DFI PHY clock cycles between when the dfi_cs signal is asserted and when the associated dfi_parity_in signal is driven.
Unit: DFI PHY clock cycles.
Programming Mode: Quasi-dynamic Group 4

Bits 20:16 – DFI_T_WRDATA_DELAY[4:0] Specifies the number of DFI clock cycles between when the dfi_wrdata_en signal is asserted and when the corresponding write data transfer is completed on the DRAM bus.
This corresponds to the DFI timing parameter twrdata_delay. Refer to PHY specification for correct value.
For DFI 3.0 PHY, set to twrdata_delay, a new timing parameter introduced in DFI 3.0.
For DFI 2.1 PHY, set to tphy_wrdata + (delay of DFI write data to the DRAM).
Value to be programmed is in terms of DFI clocks, not PHY clocks.
In FREQ_RATIO=2, divide PHY's value by 2 and round up to next integer.
If using DFITMG0.dfi_wrdata_use_dfi_phy_clk=1, add 1 to the value.
Unit: DFI clock cycles.
Programming Mode: Quasi-dynamic Group 4

Bits 12:8 – DFI_T_DRAM_CLK_DISABLE[4:0] Specifies the number of DFI clock cycles from the assertion of the dfi_dram_clk_disable signal on the DFI until the clock to the DRAM memory devices, at the PHY-DRAM boundary, maintains a low value. If the DFI clock and the memory clock are not phase aligned, this timing parameter should be rounded up to the next integer value.
Unit: DFI clock cycles.
Programming Mode: Quasi-dynamic Group 4

Bits 4:0 – DFI_T_DRAM_CLK_ENABLE[4:0] Specifies the number of DFI clock cycles from the de-assertion of the dfi_dram_clk_disable signal on the DFI until the first valid rising edge of the clock to the DRAM memory devices, at the PHY-DRAM boundary. If the DFI clock and the memory clock are not phase aligned, this timing parameter should be rounded up to the next integer value.
Unit: DFI clock cycles.
Programming Mode: Quasi-dynamic Group 4

17.6.41 UDDRC DFI Low Power Configuration Register 0

Name: UDDRC_DFILPCFG0
Offset: 0x198
Reset: 0x07000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
				DFI_TLP_RESP[4:0]				
Access				R/W	R/W	R/W	R/W	R/W

Reset	0	0	0	0				0

Bits 28:24 – DFI_TLP_RESP[4:0] Setting in DFI clock cycles for DFI's tlp_resp time.
Same value is used for both Power Down, Self Refresh, Deep Power Down and Maximum Power Saving modes.
Refer to PHY databook for recommended values
Unit: DFI clock cycles.
Programming Mode: Static

Bits 23:20 – DFI_LP_WAKEUP_DPD[3:0] Value in DFI clock cycles to drive on dfi_lp_wakeup signal when Deep Power Down mode is entered.
Determines the DFI's tlp_wakeup time:
- 0x0 - 16 cycles
- 0x1 - 32 cycles
- 0x2 - 64 cycles
- 0x3 - 128 cycles
- 0x4 - 256 cycles
- 0x5 - 512 cycles
- 0x6 - 1024 cycles
- 0x7 - 2048 cycles
- 0x8 - 4096 cycles
- 0x9 - 8192 cycles
- 0xA - 16384 cycles
- 0xB - 32768 cycles
- 0xC - 65536 cycles
- 0xD - 131072 cycles
- 0xE - 262144 cycles
- 0xF - Unlimited

This is only present for designs supporting LPDDR2/LPDDR3 devices.
Unit: DFI clock cycles.

Programming Mode: Static

Bit 16 – DFI_LP_EN_DPD Enables DFI Low Power interface handshaking during Deep Power Down Entry/Exit.
This is only present for designs supporting LPDDR2/LPDDR3 devices.
Programming Mode: Static

Value	Description
0	Disabled
1	Enabled

Bits 15:12 – DFI_LP_WAKEUP_SR[3:0] Value in DFI clock cycles to drive on dfi_lp_wakeup signal when Self Refresh mode is entered.
Determines the DFI's tlp_wakeup time:
- 0x0 - 16 cycles
- 0x1 - 32 cycles
- 0x2 - 64 cycles
- 0x3 - 128 cycles
- 0x4 - 256 cycles
- 0x5 - 512 cycles
- 0x6 - 1024 cycles
- 0x7 - 2048 cycles
- 0x8 - 4096 cycles
- 0x9 - 8192 cycles
- 0xA - 16384 cycles
- 0xB - 32768 cycles
- 0xC - 65536 cycles
- 0xD - 131072 cycles
- 0xE - 262144 cycles
- 0xF - Unlimited

Unit: DFI clock cycles.
Programming Mode: Static

Bit 8 – DFI_LP_EN_SR Enables DFI Low Power interface handshaking during Self Refresh Entry/Exit.
Programming Mode: Static

Value	Description
0	Disabled
1	Enabled

Bits 7:4 – DFI_LP_WAKEUP_PD[3:0] Value in DFI clock cycles to drive on dfi_lp_wakeup signal when Power Down mode is entered.
Determines the DFI's tlp_wakeup time:
- 0x0 - 16 cycles
- 0x1 - 32 cycles
- 0x2 - 64 cycles
- 0x3 - 128 cycles
- 0x4 - 256 cycles
- 0x5 - 512 cycles
- 0x6 - 1024 cycles
- 0x7 - 2048 cycles
- 0x8 - 4096 cycles
- 0x9 - 8192 cycles
- 0xA - 16384 cycles
- 0xB - 32768 cycles
- 0xC - 65536 cycles
- 0xD - 131072 cycles
- 0xE - 262144 cycles
- 0xF - Unlimited

Unit: DFI clock cycles.
Programming Mode: Static

Bit 0 – DFI_LP_EN_PD Enables DFI Low Power interface handshaking during Power Down Entry/Exit.
Programming Mode: Static

Value	Description
0	Disabled
1	Enabled

17.6.42 UDDRC DFI Update Register 0

Name: UDDRC_DFIUPD0
Offset: 0x1A0
Reset: 0x00400003
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
	DIS_AUTO_CTRLUPD	DIS_AUTO_CTRLUPD_SRX	CTRLUPD_PRE_SRX				DFI_T_CTRLUP_MAX[9:8]	
Access	R/W	R/W	R/W				R/W	R/W
Reset	0	0	0				0	0

Bit	23	22	21	20	19	18	17	16
	DFI_T_CTRLUP_MAX[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	1	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
							DFI_T_CTRLUP_MIN[9:8]	
Access							R/W	R/W
Reset							0	0

Bit	7	6	5	4	3	2	1	0
	DFI_T_CTRLUP_MIN[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	1	1

Bit 31 – DIS_AUTO_CTRLUPD When '1', disable the automatic dfi_ctrlupd_req generation by the UDDRC. The core must issue the dfi_ctrlupd_req signal using register DBGCMD.ctrlupd.
When '0', UDDRC issues dfi_ctrlupd_req periodically.
Programming Mode: Quasi-dynamic Group 3

Bit 30 – DIS_AUTO_CTRLUPD_SRX When '1', disable the automatic dfi_ctrlupd_req generation by the UDDRC at self-refresh exit.
When '0', UDDRC issues a dfi_ctrlupd_req before or after exiting self-refresh, depending on DFIUPD0.ctrlupd_pre_srx.
Programming Mode: Static

Bit 29 – CTRLUPD_PRE_SRX Selects dfi_ctrlupd_req requirements at SRX:
If DFIUPD0.dis_auto_ctrlupd_srx=1, this register has no impact, because no dfi_ctrlupd_req will be issued when SRX.
Programming Mode: Static

Value	Description
0	Send ctrlupd after SRX.
1	Send ctrlupd before SRX.

Bits 25:16 – DFI_T_CTRLUP_MAX[9:0] Specifies the maximum number of DFI clock cycles that the dfi_ctrlupd_req signal can assert. Lowest value to assign to this variable is 0x40.
Unit: DFI clock cycles.
Programming Mode: Static

Bits 9:0 – DFI_T_CTRLUP_MIN[9:0] Specifies the minimum number of DFI clock cycles that the dfi_ctrlupd_req signal must be asserted. The UDDRC expects the PHY to respond within this time. If the PHY does not respond, the UDDRC will de-assert dfi_ctrlupd_req after dfi_t_ctrlup_min + 2 cycles. Lowest value to assign to this variable is 0x3.
Unit: DFI clock cycles.

Programming Mode: Static

17.6.43 UDDRC DFI Update Register 1

Name: UDDRC_DFIUPD1
Offset: 0x1A4
Reset: 0x00010001
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
	DFI_T_CTRLUPD_INTERVAL_MIN_X1024[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	1

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
	DFI_T_CTRLUPD_INTERVAL_MAX_X1024[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	1

Bits 23:16 – DFI_T_CTRLUPD_INTERVAL_MIN_X1024[7:0] This is the minimum amount of time between UDDRC initiated DFI update requests (which is executed whenever the UDDRC is idle). Set this number higher to reduce the frequency of update requests, which can have a small impact on the latency of the first read request when the UDDRC is idle. Minimum allowed value for this field is 1.
Unit: Multiples of 1024 DFI clock cycles.
Programming Mode: Static

Bits 7:0 – DFI_T_CTRLUPD_INTERVAL_MAX_X1024[7:0] This is the maximum amount of time between UDDRC initiated DFI update requests. This timer resets with each update request; when the timer expires dfi_ctrlupd_req is sent and traffic is blocked until the dfi_ctrlupd_ackx is received. PHY can use this idle time to recalibrate the delay lines to the DLLs. The DFI controller update is also used to reset PHY FIFO pointers in case of data capture errors. Updates are required to maintain calibration over PVT, but frequent updates may impact performance. Minimum allowed value for this field is 1.
Unit: Multiples of 1024 DFI clock cycles.
Programming Mode: Static
Note: Value programmed for DFIUPD1.dfi_t_ctrlupd_interval_max_x1024 must be greater than DFIUPD1.dfi_t_ctrlupd_interval_min_x1024.

17.6.44 UDDRC DFI Update Register 2

Name: UDDRC_DFIUPD2
Offset: 0x1A8
Reset: 0x80000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24

Bit	15	14	13	12	11	10	9	8
				DFI_FREQUENCY[4:0]				
Access				R/W	R/W	R/W	R/W	R/W
Reset				0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
			DFI_INIT_START	CTL_IDLE_EN				DFI_INIT_COMPLETE_EN
Access			R/W	R/W				R/W
Reset			0	0				1

Bits 12:8 – DFI_FREQUENCY[4:0] Indicates the operating frequency of the system. The number of supported frequencies and the mapping of signal values to clock frequencies are defined by the PHY.
Programming Mode: Quasi-dynamic Group 1

Bit 5 – DFI_INIT_START PHY init start request signal. When asserted it triggers the PHY init start request.
Programming Mode: Quasi-dynamic Group 3

Bit 4 – CTL_IDLE_EN Enables support of ctl_idle signal.
Programming Mode: Static

Bit 0 – DFI_INIT_COMPLETE_EN PHY initialization complete enable signal.
When asserted the dfi_init_complete signal can be used to trigger SDRAM initialisation
Programming Mode: Quasi-dynamic Group 3

17.6.46 UDDRC DFI Status Register

Name: UDDRC_DFISTAT
Offset: 0x1BC
Reset: 0x00000000
Property: Read-only

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
							DFI_LP_ACK	DFI_INIT_COMPLETE
Access							R	R
Reset							0	0

Bit 1 – DFI_LP_ACK Stores the value of the dfi_lp_ack input to the controller.
Programming Mode: Dynamic

Bit 0 – DFI_INIT_COMPLETE The status flag register which announces when the DFI initialization has been completed. The DFI INIT triggered by dfi_init_start signal and then the dfi_init_complete flag is polled to know when the initialization is done.
Programming Mode: Dynamic

17.6.47 UDDRC DFI PHY Host

Name: UDDRC_DFIPHYMSTR
Offset: 0x1C4
Reset: 0x00000001
Property: Read/Write

Reset			0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
			ADDRMAP_BANK_B0[5:0]					
Access			R/W	R/W	R/W	R/W	R/W	R/W
Reset			0	0	0	0	0	0

Bits 21:16 – ADDRMAP_BANK_B2[5:0] Selects the HIF address bit used as bank address bit 2.
Valid Range: 0 to 31, and 63
Internal Base: 4
The selected HIF address bit is determined by adding the internal base to the value of this field.
If unused, set to 63 and then bank address bit 2 is set to 0.
Programming Mode: Static

Bits 13:8 – ADDRMAP_BANK_B1[5:0] Selects the HIF address bits used as bank address bit 1.
Valid Range: 0 to 32, and 63
Internal Base: 3
The selected HIF address bit for each of the bank address bits is determined by adding the internal base to the value of this field.
If unused, set to 63 and then bank address bit 1 is set to 0.
Programming Mode: Static

Bits 5:0 – ADDRMAP_BANK_B0[5:0] Selects the HIF address bits used as bank address bit 0.
Valid Range: 0 to 32, and 63
Internal Base: 2
The selected HIF address bit for each of the bank address bits is determined by adding the internal base to the value of this field.
If unused, set to 63 and then bank address bit 0 is set to 0.
Programming Mode: Static

17.6.49 UDDRC Address Map Register 2

Name: UDDRC_ADDRMAP2
Offset: 0x208
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
					ADDRMAP_COL_B5[3:0]			
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

					ADDRMAP_COL_B4[3:0]			
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0
Bit	15	14	13	12	11	10	9	8
				ADDRMAP_COL_B3[4:0]				
Access				R/W	R/W	R/W	R/W	R/W
Reset				0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
					ADDRMAP_COL_B2[3:0]			
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bits 27:24 – ADDRMAP_COL_B5[3:0]
- Full bus width mode: Selects the HIF address bit used as column address bit 5.
- Half bus width mode: Selects the HIF address bit used as column address bit 6.
- Quarter bus width mode: Selects the HIF address bit used as column address bit 7.

Valid Range: 0 to 7, and 15
Internal Base: 5
The selected HIF address bit is determined by adding the internal base to the value of this field.
If unused, set to 15 and then this column address bit is set to 0.
Programming Mode: Static

Bits 19:16 – ADDRMAP_COL_B4[3:0]
- Full bus width mode: Selects the HIF address bit used as column address bit 4.
- Half bus width mode: Selects the HIF address bit used as column address bit 5.
- Quarter bus width mode: Selects the HIF address bit used as column address bit 6.

Valid Range: 0 to 7, and 15
Internal Base: 4
The selected HIF address bit is determined by adding the internal base to the value of this field.
If unused, set to 15 and then this column address bit is set to 0.
Programming Mode: Static

Bits 12:8 – ADDRMAP_COL_B3[4:0]
- Full bus width mode: Selects the HIF address bit used as column address bit 3.
- Half bus width mode: Selects the HIF address bit used as column address bit 4.
- Quarter bus width mode: Selects the HIF address bit used as column address bit 5.

Valid Range: 0 to 7.
Internal Base: 3
The selected HIF address bit is determined by adding the internal base to the value of this field.

Programming Mode: Static

Bits 3:0 – ADDRMAP_COL_B2[3:0]

- Full bus width mode: Selects the HIF address bit used as column address bit 2.
- Half bus width mode: Selects the HIF address bit used as column address bit 3.

Valid Range: 0 to 7
Internal Base: 2
The selected HIF address bit is determined by adding the internal base to the value of this field.
Note it is required to program this to 0 unless:

- in Half bus width (MSTR.data_bus_width!=00) and
- PCCFG.bl_exp_mode==1

Otherwise, if Full Bus Width (MSTR.data_bus_width)==00), it is recommended to program this to 0 so that HIF[2] maps to column address bit 2.
Programming Mode: Static

17.6.50 UDDRC Address Map Register 3

Name: UDDRC_ADDRMAP3
Offset: 0x20C
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
				ADDRMAP_COL_B9[4:0]				
Access				R/W	R/W	R/W	R/W	R/W

				ADDRMAP_COL_B6[4:0]				
Access				R/W	R/W	R/W	R/W	R/W
Reset				0	0	0	0	0

Bits 28:24 – ADDRMAP_COL_B9[4:0]
- Full bus width mode: Selects the HIF address bit used as column address bit 9.
- Half bus width mode: Selects the HIF address bit used as column address bit 11 (10 in LPDDR2/LPDDR3 mode).
- Quarter bus width mode: Selects the HIF address bit used as column address bit 13 (11 in LPDDR2/LPDDR3 mode).
Valid Range: 0 to 7, and 31.
Internal Base: 9
The selected HIF address bit is determined by adding the internal base to the value of this field.
In LPDDR2/LPDDR3, there is a dedicated bit for auto-precharge in the CA bus and hence column bit 10 is used.
If column bit 9 is the highest column address bit, it must map to the highest valid HIF address bit. (x = the highest valid HIF address bit - internal base)
If column bit 9 is the second highest column address bit, it must map to the second highest valid HIF address bit. (x = the highest valid HIF address bit - 1 - internal base)
If column bit 9 is the third highest column address bit, it must map to the third highest valid HIF address bit. (x = the highest valid HIF address bit - 2 - internal base)
If unused, set to 31 and then this column address bit is set to 0.
Programming Mode: Static
Note: Per JEDEC DDR2/3 specification, column address bit 10 is reserved for indicating auto-precharge, and hence no source address bit can be mapped to column address bit 10.

Bits 20:16 – ADDRMAP_COL_B8[4:0]
- Full bus width mode: Selects the HIF address bit used as column address bit 8.
- Half bus width mode: Selects the HIF address bit used as column address bit 9.
- Quarter bus width mode: Selects the HIF address bit used as column address bit 11 (10 in LPDDR2/LPDDR3 mode).
Valid Range: 0 to 7, and 31.
Internal Base: 8
The selected HIF address bit is determined by adding the internal base to the value of this field.
In LPDDR2/LPDDR3, there is a dedicated bit for auto-precharge in the CA bus and hence column bit 10 is used.

If column bit 8 is the second highest column address bit, it must map to the second highest valid HIF address bit. (x = the highest valid HIF address bit - 1 - internal base)
If column bit 8 is the third highest column address bit, it must map to the third highest valid HIF address bit. (x = the highest valid HIF address bit - 2 - internal base)
If unused, set to 31 and then this column address bit is set to 0.
Programming Mode: Static
Note: Per JEDEC DDR2/3 specification, column address bit 10 is reserved for indicating auto-precharge, and hence no source address bit can be mapped to column address bit 10.

Bits 12:8 – ADDRMAP_COL_B7[4:0]
- Full bus width mode: Selects the HIF address bit used as column address bit 7.
- Half bus width mode: Selects the HIF address bit used as column address bit 8.
- Quarter bus width mode: Selects the HIF address bit used as column address bit 9.
Valid Range: 0 to 7, and 31.
Internal Base: 7
The selected HIF address bit is determined by adding the internal base to the value of this field.
If column bit 7 is the third highest column address bit, it must map to the third highest valid HIF address bit. (x = the highest valid HIF address bit - 2 - internal base)
If unused, set to 31 and then this column address bit is set to 0.
Programming Mode: Static

Bits 4:0 – ADDRMAP_COL_B6[4:0]
- Full bus width mode: Selects the HIF address bit used as column address bit 6.
- Half bus width mode: Selects the HIF address bit used as column address bit 7.
- Quarter bus width mode: Selects the HIF address bit used as column address bit 8.
Valid Range: 0 to 7.
Internal Base: 6
The selected HIF address bit is determined by adding the internal base to the value of this field.
If unused, set to 31 and then this column address bit is set to 0.
Programming Mode: Static

17.6.51 UDDRC Address Map Register 4

Name: UDDRC_ADDRMAP4

- Full bus width mode: Selects the HIF address bit used as column address bit 13 (11 in LPDDR2/LPDDR3 mode).
- Half bus width mode: UNUSED. See later in this description for value you need to set to make it unused.
- Quarter bus width mode: UNUSED. See later in this description for value you need to set to make it unused.
Valid Range: 0 to 7, and 31.
Internal Base: 11
The selected HIF address bit is determined by adding the internal base to the value of this field.
In LPDDR2/LPDDR3, there is a dedicated bit for auto-precharge in the CA bus and hence column bit 10 is used.
If column bit 11 is the highest column address bit, it must map to the highest valid HIF address bit. (x = the highest valid HIF address bit - internal base)
If column bit 11 is the second highest column address bit, it must map to the second highest valid HIF address bit. (x = the highest valid HIF address bit - 1 - internal base)
If column bit 11 is the third highest column address bit, it must map to the third highest valid HIF address bit. (x = the highest valid HIF address bit - 2 - internal base)
If unused, set to 31 and then this column address bit is set to 0.
Programming Mode: Static
Note: Per JEDEC DDR2/3 specification, column address bit 10 is reserved for indicating auto-precharge, and hence no source address bit can be mapped to column address bit 10.

Bits 4:0 – ADDRMAP_COL_B10[4:0]
- Full bus width mode: Selects the HIF address bit used as column address bit 11 (10 in LPDDR2/LPDDR3 mode).
- Half bus width mode: Selects the HIF address bit used as column address bit 13 (11 in LPDDR2/LPDDR3 mode).
- Quarter bus width mode: UNUSED. See later in this description for value you need to set to make it unused.
Valid Range: 0 to 7, and 31.
Internal Base: 10
The selected HIF address bit is determined by adding the internal base to the value of this field.
In LPDDR2/LPDDR3, there is a dedicated bit for auto-precharge in the CA bus and hence column bit 10 is used.
If column bit 10 is the highest column address bit, it must map to the highest valid HIF address bit. (x = the highest valid HIF address bit - internal base)

If column bit 10 is the second highest column address bit, it must map to the second highest valid HIF address bit. (x = the highest valid HIF address bit - 1 - internal base)
If column bit 10 is the third highest column address bit, it must map to the third highest valid HIF address bit. (x = the highest valid HIF address bit - 2 - internal base)
If unused, set to 31 and then this column address bit is set to 0.
Programming Mode: Static
Note: Per JEDEC DDR2/3 specification, column address bit 10 is reserved for indicating auto-precharge, and hence no source address bit can be mapped to column address bit 10.

17.6.52 UDDRC Address Map Register 5

Name: UDDRC_ADDRMAP5
Offset: 0x214
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
					ADDRMAP_ROW_B11[3:0]			
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bit	23	22	21	20	19	18	17	16
					ADDRMAP_ROW_B2_10[3:0]			
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bit	15	14	13	12	11	10	9	8
					ADDRMAP_ROW_B1[3:0]			
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bit	7	6	5	4	3	2	1	0
					ADDRMAP_ROW_B0[3:0]			
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bits 27:24 – ADDRMAP_ROW_B11[3:0] Selects the HIF address bit used as row address bit 11.
Valid Range: 0 to 11, and 15
Internal Base: 17
The selected HIF address bit is determined by adding the internal base to the value of this field.
If unused, set to 15 and then row address bit 11 is set to 0.
Programming Mode: Static

Bits 19:16 – ADDRMAP_ROW_B2_10[3:0] Selects the HIF address bits used as row address bits 2 to 10.
Valid Range: 0 to 11, and 15
Internal Base: 8 (for row address bit 2), 9 (for row address bit 3), 10 (for row address bit 4) etc increasing to 16 (for row address bit 10)
The selected HIF address bit for each of the row address bits is determined by adding the internal base to the value of this field.
When set to 15, the values of row address bits 2 to 10 are defined by registers ADDRMAP9, ADDRMAP10, ADDRMAP11.
Programming Mode: Static

Bits 11:8 – ADDRMAP_ROW_B1[3:0] Selects the HIF address bits used as row address bit 1.
Valid Range: 0 to 11
Internal Base: 7
The selected HIF address bit for each of the row address bits is determined by adding the internal base to the value of this field.
Programming Mode: Static

Bits 3:0 – ADDRMAP_ROW_B0[3:0] Selects the HIF address bits used as row address bit 0.
Valid Range: 0 to 11
Internal Base: 6
The selected HIF address bit for each of the row address bits is determined by adding the internal base to the value of this field.
Programming Mode: Static

17.6.53 UDDRC Address Map Register 6

Name: UDDRC_ADDRMAP6
Offset: 0x218
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
	LPDDR3_6GB_12GB				ADDRMAP_ROW_B15[3:0]			
Access	R/W				R/W	R/W	R/W	R/W
Reset	0				0	0	0	0

Bit	23	22	21	20	19	18	17	16

Reset					0	0	0	0

Bit	7	6	5	4	3	2	1	0
					ADDRMAP_ROW_B12[3:0]			
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bit 31 – LPDDR3_6GB_12GB
Set this to 1 if there is an LPDDR3 SDRAM 6Gb or 12Gb device in use.
Present only in designs configured to support LPDDR3.
Programming Mode: Static

Value	Description
0	Non-LPDDR3 6Gb/12Gb device in use. All addresses are valid.
1	LPDDR3 SDRAM 6Gb/12Gb device in use. Every address having row[14:13]==2'b11 is considered as invalid.

Bits 27:24 – ADDRMAP_ROW_B15[3:0] Selects the HIF address bit used as row address bit 15.
Valid Range: 0 to 11, and 15
Internal Base: 21
The selected HIF address bit is determined by adding the internal base to the value of this field.
If unused, set to 15 and then row address bit 15 is set to 0.
Programming Mode: Static

Bits 19:16 – ADDRMAP_ROW_B14[3:0] Selects the HIF address bit used as row address bit 14.
Valid Range: 0 to 11, and 15
Internal Base: 20
The selected HIF address bit is determined by adding the internal base to the value of this field.
If unused, set to 15 and then row address bit 14 is set to 0.
Programming Mode: Static

Bits 11:8 – ADDRMAP_ROW_B13[3:0] Selects the HIF address bit used as row address bit 13.
Valid Range: 0 to 11, and 15
Internal Base: 19
The selected HIF address bit is determined by adding the internal base to the value of this field.
If unused, set to 15 and then row address bit 13 is set to 0.
Programming Mode: Static

Bits 3:0 – ADDRMAP_ROW_B12[3:0] Selects the HIF address bit used as row address bit 12.
Valid Range: 0 to 11, and 15
Internal Base: 18
The selected HIF address bit is determined by adding the internal base to the value of this field.
If unused, set to 15 and then row address bit 12 is set to 0.
Programming Mode: Static

17.6.54 UDDRC Address Map Register 9

Name: UDDRC_ADDRMAP9
Offset: 0x224
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24

Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bits 27:24 – ADDRMAP_ROW_B5[3:0] Selects the HIF address bits used as row address bit 5.
Valid Range: 0 to 11
Internal Base: 11
The selected HIF address bit for each of the row address bits is determined by adding the internal base to the value of this field. This register field is used only when ADDRMAP5.addrmap_row_b2_10 is set to value 15.
Programming Mode: Static

Bits 19:16 – ADDRMAP_ROW_B4[3:0] Selects the HIF address bits used as row address bit 4.
Valid Range: 0 to 11
Internal Base: 10
The selected HIF address bit for each of the row address bits is determined by adding the internal base to the value of this field. This register field is used only when ADDRMAP5.addrmap_row_b2_10 is set to value 15.
Programming Mode: Static

Bits 11:8 – ADDRMAP_ROW_B3[3:0] Selects the HIF address bits used as row address bit 3.
Valid Range: 0 to 11
Internal Base: 9
The selected HIF address bit for each of the row address bits is determined by adding the internal base to the value of this field. This register field is used only when ADDRMAP5.addrmap_row_b2_10 is set to value 15.
Programming Mode: Static

Bits 3:0 – ADDRMAP_ROW_B2[3:0] Selects the HIF address bits used as row address bit 2.
Valid Range: 0 to 11
Internal Base: 8
The selected HIF address bit for each of the row address bits is determined by adding the internal base to the value of this field. This register field is used only when ADDRMAP5.addrmap_row_b2_10 is set to value 15.
Programming Mode: Static

17.6.55 UDDRC Address Map Register 10

Name: UDDRC_ADDRMAP10
Offset: 0x228
Reset: 0x00000000
Property: Read/Write

					ADDRMAP_ROW_B6[3:0]			
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bits 27:24 – ADDRMAP_ROW_B9[3:0] Selects the HIF address bits used as row address bit 9.
Valid Range: 0 to 11
Internal Base: 15
The selected HIF address bit for each of the row address bits is determined by adding the internal base to the value of this field. This register field is used only when ADDRMAP5.addrmap_row_b2_10 is set to value 15.
Programming Mode: Static

Bits 19:16 – ADDRMAP_ROW_B8[3:0] Selects the HIF address bits used as row address bit 8.
Valid Range: 0 to 11
Internal Base: 14
The selected HIF address bit for each of the row address bits is determined by adding the internal base to the value of this field. This register field is used only when ADDRMAP5.addrmap_row_b2_10 is set to value 15.
Programming Mode: Static

Bits 11:8 – ADDRMAP_ROW_B7[3:0] Selects the HIF address bits used as row address bit 7.
Valid Range: 0 to 11
Internal Base: 13
The selected HIF address bit for each of the row address bits is determined by adding the internal base to the value of this field. This register field is used only when ADDRMAP5.addrmap_row_b2_10 is set to value 15.
Programming Mode: Static

Bits 3:0 – ADDRMAP_ROW_B6[3:0] Selects the HIF address bits used as row address bit 6.
Valid Range: 0 to 11
Internal Base: 12
The selected HIF address bit for each of the row address bits is determined by adding the internal base to the value of this field. This register field is used only when ADDRMAP5.addrmap_row_b2_10 is set to value 15.
Programming Mode: Static

17.6.56 UDDRC Address Map Register 11

Name: UDDRC_ADDRMAP11
Offset: 0x22C
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access

					ADDRMAP_ROW_B10[3:0]			
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bits 3:0 – ADDRMAP_ROW_B10[3:0] Selects the HIF address bits used as row address bit 10.
Valid Range: 0 to 11
Internal Base: 16
The selected HIF address bit for each of the row address bits is determined by adding the internal base to the value of this field. This register field is used only when ADDRMAP5.addrmap_row_b2_10 is set to value 15.
Programming Mode: Static

17.6.57 UDDRC ODT Configuration Register

Name: UDDRC_ODTCFG
Offset: 0x240
Reset: 0x04000400
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
					WR_ODT_HOLD[3:0]			
Access					R/W	R/W	R/W	R/W
Reset					0	1	0	0

Bit	23	22	21	20	19	18	17	16
				WR_ODT_DELAY[4:0]				
Access				R/W	R/W	R/W	R/W	R/W
Reset				0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
					RD_ODT_HOLD[3:0]			
Access					R/W	R/W	R/W	R/W
Reset					0	1	0	0

Bit	7	6	5	4	3	2	1	0
		RD_ODT_DELAY[4:0]						
Access		R/W	R/W	R/W	R/W	R/W		
Reset		0	0	0	0	0		

Bits 27:24 – WR_ODT_HOLD[3:0]
DFI PHY clock cycles to hold ODT for a write command. The minimum supported value is 2.
Recommended values:
DDR2:
- BL8: 0x5 (DDR2-400/533/667), 0x6 (DDR2-800), 0x7 (DDR2-1066)
- BL4: 0x3 (DDR2-400/533/667), 0x4 (DDR2-800), 0x5 (DDR2-1066)
DDR3:
- BL8: 0x6
WR_PREAMBLE = 1 (1tCK write preamble), 2 (2tCK write preamble)
CRC_MODE = 0 (not CRC mode), 1 (CRC mode)
LPDDR3:
- BL8: 7 + RU(tODTon(max)/tCK)
Unit: DFI PHY clock cycles.
Programming Mode: Quasi-dynamic Group 1, Group 4

Bits 20:16 – WR_ODT_DELAY[4:0]
The delay, in DFI PHY clock cycles, from issuing a write command to setting ODT values associated with that command. ODT setting must remain constant for the entire time that DQS is driven by the UDDRC.
Recommended values:
DDR2:
- CWL + AL - 3 (DDR2-400/533/667), CWL + AL - 4 (DDR2-800), CWL + AL - 5 (DDR2-1066)
If (CWL + AL - 3 < 0), UDDRC does not support ODT for write operation.
DDR3:
- 0x0
LPDDR3:
- WL - 1 - RU(tODTon(max)/tCK))
Unit: DFI PHY clock cycles.
Programming Mode: Quasi-dynamic Group 1, Group 4

Bits 11:8 – RD_ODT_HOLD[3:0]
DFI PHY clock cycles to hold ODT for a read command. The minimum supported value is 2.
Recommended values:
DDR2:
- BL8: 0x6 (not DDR2-1066), 0x7 (DDR2-1066)
- BL4: 0x4 (not DDR2-1066), 0x5 (DDR2-1066)
DDR3:
- BL8 - 0x6
LPDDR3:
- BL8: 5 + RU(tDQSCK(max)/tCK) - RD(tDQSCK(min)/tCK) + RU(tODTon(max)/tCK)
Unit: DFI PHY clock cycles.
Programming Mode: Quasi-dynamic Group 1, Group 4

Bits 6:2 – RD_ODT_DELAY[4:0]
The delay, in DFI PHY clock cycles, from issuing a read command to setting ODT values associated with that command. ODT setting must remain constant for the entire time that DQS is driven by the UDDRC.
Recommended values:
DDR2:
- CL + AL - 4 (not DDR2-1066), CL + AL - 5 (DDR2-1066)
If (CL + AL - 4 < 0), UDDRC does not support ODT for read operation.
DDR3:
- CL - CWL
LPDDR3:
- RL + RD(tDQSCK(min)/tCK) - 1 - RU(tODTon(max)/tCK)
Unit: DFI PHY clock cycles.
Programming Mode: Quasi-dynamic Group 1, Group 4

17.6.58 UDDRC ODT/Rank Map Register

Name: UDDRC_ODTMAP
Offset: 0x244
Reset: 0x00000011
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
				RANK0_RD_ODT				RANK0_WR_ODT
Access				R/W				R/W
Reset				1				1

Bit 4 – RANK0_RD_ODT Indicates which remote ODTs must be turned on during a read from rank 0.
Each rank has a remote ODT (in the SDRAM) which can be turned on by setting the appropriate bit here.
Rank 0 is controlled by the LSB; rank 1 is controlled by bit next to the LSB, etc.
For each rank, set its bit to 1 to enable its ODT.
Programming Mode: Static

Bit 0 – RANK0_WR_ODT Indicates which remote ODTs must be turned on during a write to rank 0.
Each rank has a remote ODT (in the SDRAM) which can be turned on by setting the appropriate bit here.
Rank 0 is controlled by the LSB; rank 1 is controlled by bit next to the LSB, etc.
For each rank, set its bit to 1 to enable its ODT.
Programming Mode: Static

17.6.59 UDDRC Scheduler Control Register 0

Name: UDDRC_SCHED
Offset: 0x250
Reset: 0x00001005
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
		RDWR_IDLE_GAP[6:0]						
Access		R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset		0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	GO2CRITICAL_HYSTERESIS[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
				LPR_NUM_ENTRIES[4:0]				
Access				R/W	R/W	R/W	R/W	R/W
Reset				1	0	0	0	0

Bit	7	6	5	4	3	2	1	0
						PAGECLOSE	PREFER_WRITE	FORCE_LOW_PRI_N
Access						R/W	R/W	R/W
Reset						1	0	1

Bits 30:24 – RDWR_IDLE_GAP[6:0] When the preferred transaction store is empty for these many clock cycles, switch to the alternate transaction store if it is non-empty.
The read transaction store (both high and low priority) is the default preferred transaction store and the write transaction store is the alternative store.
When prefer write over read is set this is reversed.
0x0 is a legal value for this register. When set to 0x0, the transaction store switching will happen immediately when the switching conditions become true.
For performance only.
Unit: DFI clock cycles.
Programming Mode: Static

Bits 23:16 – GO2CRITICAL_HYSTERESIS[7:0] UNUSED
Programming Mode: Static

Bits 12:8 – LPR_NUM_ENTRIES[4:0] Number of entries in the low priority transaction store is this value + 1.
(2 - (SCHED.lpr_num_entries + 1)) is the number of entries available for the high priority transaction store.
Setting this to maximum value allocates all entries to low priority transaction store.
Setting this to 0 allocates 1 entry to low priority transaction store and the rest to high priority transaction store.
Programming Mode: Static

Bit 2 – PAGECLOSE If true, bank is kept open only while there are page hit transactions available in the CAM to that bank. The last read or write command in the CAM with a bank and page hit will be executed with auto-precharge if SCHED1.pageclose_timer=0. Even if this register set to 1 and SCHED1.pageclose_timer is set to 0, explicit precharge (and not auto-precharge) may be issued in some cases where there is a mode switch between Write and Read or between LPR and HPR.
If false, the bank remains open until there is a need to close it (to open a different page, or for page timeout or refresh timeout) - also known as open page policy. The open page policy can be overridden by setting the per-command-autopre bit on the HIF interface (hif_cmd_autopre).
The pageclose feature provids a midway between Open and Close page policies.

For performance only.
Programming Mode: Quasi-dynamic Group 3

Bit 1 – PREFER_WRITE If set then the bank selector prefers writes over reads.
For debug only.
Programming Mode: Static

Bit 0 – FORCE_LOW_PRI_N Active low signal. When asserted ('0'), all incoming transactions are forced to low priority. This implies that all High Priority Read (HPR) and Variable Priority Read commands (VPR) will be treated as Low Priority Read (LPR) commands. On the write side, all Variable Priority Write (VPW) commands will be treated as Normal Priority Write (NPW) commands. Forcing the incoming transactions to low priority implicitly turns off Bypass path for read commands.
For performance only.
Programming Mode: Static

17.6.60 UDDRC Scheduler Control Register 1

Name: UDDRC_SCHED1
Offset: 0x254
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
	PAGECLOSE_TIMER[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 7:0 – PAGECLOSE_TIMER[7:0] This field works in conjunction with UDDRC_SCHED.PAGECLOSE.
It only has meaning if UDDRC_SCHED.PAGECLOSE=1.
If UDDRC_SCHED.PAGECLOSE=1 and UDDRC_SCHED1.PAGECLOSE=0, then an auto-precharge may be scheduled for last read or write command in the CAM with a bank and page hit.
Note, sometimes an explicit precharge is scheduled instead of the auto-precharge. See UDDRC_SCHED.PAGECLOSE for details of when this may happen.
If UDDRC_SCHED.PAGECLOSE=1 and PAGECLOSE_TIMER>0, then an auto-precharge is not scheduled for last read or write command in the CAM with a bank and page hit.
Instead, a timer is started, with PAGECLOSE_TIMER as the initial value.
There is a timer on a per bank basis.
The timer decrements unless the next read or write in the CAM to a bank is a page hit.
It gets reset to PAGECLOSE_TIMER value if the next read or write in the CAM to a bank is a page hit.
Once the timer has reached zero, an explicit precharge will be attempted to be scheduled.
Unit: DFI clock cycles.
Programming Mode: Static

17.6.61 UDDRC High Priority Read CAM Register 1

Name: UDDRC_PERFHPR1
Offset: 0x25C
Reset: 0x0F000001
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
	HPR_XACT_RUN_LENGTH[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	1	1	1	1

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
	HPR_MAX_STARVE[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	HPR_MAX_STARVE[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	1

Bits 31:24 – HPR_XACT_RUN_LENGTH[7:0]
Number of transactions that are serviced once the HPR queue goes critical is the smaller of:
- (a) This number
- (b) Number of transactions available.

Unit: Transaction.
For performance only.
Programming Mode: Quasi-dynamic Group 3

Bits 15:0 – HPR_MAX_STARVE[15:0] Number of DFI clocks that the HPR queue can be starved before it goes critical. The minimum valid functional value for this register is 0x1. Programming it to 0x0 will disable the starvation functionality; during normal operation, this function should not be disabled as it will cause excessive latencies.
For performance only.
Unit: DFI clock cycles.
Programming Mode: Quasi-dynamic Group 3

17.6.62 UDDRC Low Priority Read CAM Register 1

Name: UDDRC_PERFLPR1

	LPR_MAX_STARVE[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	1	1	1	1	1	1	1

Bits 31:24 – LPR_XACT_RUN_LENGTH[7:0]
Number of transactions that are serviced once the LPR queue goes critical is the smaller of:
- (a) This number
- (b) Number of transactions available.

Unit: Transaction.
For performance only.
Programming Mode: Quasi-dynamic Group 3

Bits 15:0 – LPR_MAX_STARVE[15:0] Number of DFI clocks that the LPR queue can be starved before it goes critical. The minimum valid functional value for this register is 0x1. Programming it to 0x0 will disable the starvation functionality; during normal operation, this function should not be disabled as it will cause excessive latencies.
For performance only.
Unit: DFI clock cycles.
Programming Mode: Quasi-dynamic Group 3

17.6.63 UDDRC Write CAM Register 1

Name: UDDRC_PERFWR1
Offset: 0x26C
Reset: 0x0F00007F
Property: Read/Write

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	1	1	1	1	1	1	1

Bits 31:24 – W_XACT_RUN_LENGTH[7:0]
Number of transactions that are serviced once the WR queue goes critical is the smaller of:
- (a) This number
- (b) Number of transactions available.

Unit: Transaction.
For performance only.
Programming Mode: Quasi-dynamic Group 3

Bits 15:0 – W_MAX_STARVE[15:0] Number of DFI clocks that the WR queue can be starved before it goes critical. The minimum valid functional value for this register is 0x1. Programming it to 0x0 will disable the starvation functionality; during normal operation, this function should not be disabled as it will cause excessive latencies.
For performance only.
Unit: DFI clock cycles.
Programming Mode: Quasi-dynamic Group 3

17.6.64 UDDRC Debug Register 0

Name: UDDRC_DBG0
Offset: 0x300
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
				DIS_COLLISION_PAGE_OPT		DIS_ACT_BYPASS	DIS_RD_BYPASS	DIS_WC
Access				R/W		R/W	R/W	R/W
Reset				0		0	0	0

Bit 4 – DIS_COLLISION_PAGE_OPT When this is set to '0', auto-precharge is disabled for the flushed command in a collision case. Collision cases are write followed by read to same address, read followed by write to same address, or write followed by write to same address with DBG0.dis_wc bit = 1 (where same address comparisons exclude the two address bits representing critical word).
For debug only.
Programming Mode: Static

Bit 2 – DIS_ACT_BYPASS Only present in designs supporting activate bypass.
When 1, disable bypass path for high priority read activates
For debug only.
Programming Mode: Static

Bit 1 – DIS_RD_BYPASS Only present in designs supporting read bypass.
When 1, disable bypass path for high priority read page hits.
For debug only.
Programming Mode: Static

Bit 0 – DIS_WC When 1, disable write combine.
For debug only
Programming Mode: Static

17.6.65 UDDRC Debug Register 1

Name: UDDRC_DBG1
Offset: 0x304
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
							DIS_HIF	DIS_DQ
Access							R/W	R/W
Reset							0	0

Bit 1 – DIS_HIF When 1, UDDRC asserts the HIF command signal hif_cmd_stall. UDDRC will ignore the hif_cmd_valid and all other associated request signals.
This bit is intended to be switched on-the-fly.
Programming Mode: Dynamic

Bit 0 – DIS_DQ When 1, UDDRC will not de-queue any transactions from the CAM. Bypass is also disabled. All transactions are queued in the CAM. No reads or writes are issued to SDRAM as long as this is asserted.
This bit may be used to prevent reads or writes being issued by the UDDRC, which makes it safe to modify certain register fields associated with reads and writes (see User Guide for details). After setting this bit, it is strongly recommended to poll DBGCAM.wr_data_pipeline_empty and DBGCAM.rd_data_pipeline_empty, before making changes to any registers which affect reads and writes. This will ensure that the relevant logic in the DDRC is idle.
This bit is intended to be switched on-the-fly.
Programming Mode: Dynamic

17.6.66 UDDRC CAM Debug Register

Name: UDDRC_DBGCAM
Offset: 0x308
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
			WR_DATA_PIPELINE_EMPTY	RD_DATA_PIPELINE_EMPTY		DBG_WR_Q_EMPTY	DBG_RD_Q_EMPTY	DBG_STALL
Access			R	R		R	R	R
Reset			0	0		0	0	0

Bit	23	22	21	20	19	18	17	16
			DBG_W_Q_DEPTH[5:0]					
Access			R	R	R	R	R	R
Reset			0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
			DBG_LPR_Q_DEPTH[5:0]					
Access			R	R	R	R	R	R
Reset			0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
			DBG_HPR_Q_DEPTH[5:0]					
Access			R	R	R	R	R	R
Reset			0	0	0	0	0	0

Bit 29 – WR_DATA_PIPELINE_EMPTY This bit indicates that the write data pipeline on the DFI interface is empty. This register is intended to be polled at least twice after setting DBG1.dis_dq, to ensure that all remaining commands/ data have completed.
Programming Mode: Dynamic

Bit 28 – RD_DATA_PIPELINE_EMPTY This bit indicates that the read data pipeline on the DFI interface is empty. This register is intended to be polled at least twice after setting DBG1.dis_dq, to ensure that all remaining commands/ data have completed.
Programming Mode: Dynamic

Bit 26 – DBG_WR_Q_EMPTY When 1, all the Write command queues and Write data buffers inside DDRC are empty. This register is to be used for debug purpose.
An example use-case scenario: When Controller enters Self-Refresh using the Low-Power entry sequence, Controller is expected to have executed all the commands in its queues and the write and read data drained. Hence this register should be 1 at that time.
For debug only
Programming Mode: Dynamic

Bit 25 – DBG_RD_Q_EMPTY When 1, all the Read command queues and Read data buffers inside DDRC are empty. This register is to be used for debug purpose.
An example use-case scenario: When Controller enters Self-Refresh using the Low-Power entry sequence, Controller is expected to have executed all the commands in its queues and the write and read data drained. Hence this register should be 1 at that time.
For debug only
Programming Mode: Dynamic

Bit 24 – DBG_STALL Stall
For debug only
Programming Mode: Dynamic

Bits 21:16 – DBG_W_Q_DEPTH[5:0] Write queue depth
This entry is not included in the calculation of the queue depth.
For debug only
Programming Mode: Dynamic

Bits 13:8 – DBG_LPR_Q_DEPTH[5:0] Low priority read queue depth
This entry is not included in the calculation of the queue depth.
For debug only
Programming Mode: Dynamic

Bits 5:0 – DBG_HPR_Q_DEPTH[5:0] High priority read queue depth
For debug only
Programming Mode: Dynamic

17.6.67 UDDRC Command Debug Register

Name: UDDRC_DBGCMD
Offset: 0x30C
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								
Bit	23	22	21	20	19	18	17	16
Access								
Reset								
Bit	15	14	13	12	11	10	9	8
Access								
Reset								
Bit	7	6	5	4	3	2	1	0
			CTRLUPD	ZQ_CALIB_SHORT				RANK0_REFRESH
Access			R/W	R/W				R/W
Reset			0	0				0

Bit 5 – CTRLUPD
Setting this register bit to 1 indicates to the UDDRC to issue a dfi_ctrlupd_req to the PHY. When this request is stored in the UDDRC, the bit is automatically cleared. This operation must only be performed when DFIUPD0.dis_auto_ctrlupd=1.
Programming Mode: Dynamic

Bit 4 – ZQ_CALIB_SHORT
Setting this register bit to 1 indicates to the UDDRC to issue a ZQCS (ZQ calibration short)/MPC(ZQ calibration) command to the SDRAM. When this request is stored in the UDDRC, the bit is automatically cleared. This operation can be performed only when ZQCTL0.dis_auto_zq=1. It is recommended NOT to set this register bit if in Init, in Self-Refresh or Deep power-down operating modes or Maximum Power Saving Mode.
For Self-Refresh it will be scheduled after SR has been exited.
For Deep power down and Maximum Power Saving Mode, it will not be scheduled, although DBGSTAT.zq_calib_short_busy will be de-asserted.
Programming Mode: Dynamic

Bit 0 – RANK0_REFRESH
Setting this register bit to 1 indicates to the UDDRC to issue a refresh to rank 0. Writing to this bit causes DBGSTAT.rank0_refresh_busy to be set. When DBGSTAT.rank0_refresh_busy is cleared, the command has been stored in UDDRC.
For 3DS configuration, refresh is sent to rank index 0.
This operation can be performed only when RFSHCTL3.dis_auto_refresh=1. It is recommended NOT to set this register bit if in Init or Deep power-down operating modes or Maximum Power Saving Mode.
Programming Mode: Dynamic

17.6.68 UDDRC Status Debug Register

Name: UDDRC_DBGSTAT
Offset: 0x310
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
			CTRLUPD_BUSY	ZQ_CALIB_SHORT_BUSY				RANK0_REFRESH_BUSY
Access			R	R				R
Reset			0	0				0

Bit 5 – CTRLUPD_BUSY SoC core may initiate a ctrlupd operation only if this signal is low.
This signal goes high in the clock after the UDDRC accepts the ctrlupd request. It goes low when the ctrlupd operation is initiated in the UDDRC.
It is recommended not to perform ctrlupd operations when this signal is high.
Programming Mode: Dynamic

Value	Description
0	Indicates that the SoC core can initiate a ctrlupd operation.
1	Indicates that ctrlupd operation has not been initiated yet in the UDDRC.

Bit 4 – ZQ_CALIB_SHORT_BUSY SoC core may initiate a ZQCS (ZQ calibration short) operation only if this signal is low. This signal goes high in the clock after the UDDRC accepts the ZQCS request. It goes low when the ZQCS operation is initiated in the UDDRC. It is recommended not to perform ZQCS operations when this signal is high.
Programming Mode: Dynamic

Value	Description
0	Indicates that the SoC core can initiate a ZQCS operation.
1	Indicates that ZQCS operation has not been initiated yet in the UDDRC.

Bit 0 – RANK0_REFRESH_BUSY SoC core may initiate a rank0_refresh operation (refresh operation to rank 0) only if this signal is low.
This signal goes high in the clock after DBGCMD.rank0_refresh is set to one. It goes low when the rank0_refresh operation is stored in the UDDRC.
It is recommended not to perform rank0_refresh operations when this signal is high.
Programming Mode: Dynamic

Value	Description
0	Indicates that the SoC core can initiate a rank0_refresh operation.
1	Indicates that rank0_refresh operation has not been stored yet in the UDDRC.

17.6.69 UDDRC Software Register Programming Control Enable

Name: UDDRC_SWCTL
Offset: 0x320

Access				R	R	R	R	R
Reset				0	0	0	0	0

Bit 20 – RD_POISON_INTR_4 Read transaction poisoning error interrupt for port 4. This register is a APB clock copy (double register synchronizer) of the interrupt asserted when a transaction is poisoned on the corresponding AXI port's read address channel. Bit 0 corresponds to Port 0, and so on. Interrupt is cleared by register rd_poison_intr_clr, then value propagated to APB clock.
Programming Mode: Dynamic

Bit 19 – RD_POISON_INTR_3 Read transaction poisoning error interrupt for port 3. This register is a APB clock copy (double register synchronizer) of the interrupt asserted when a transaction is poisoned on the corresponding AXI port's read address channel. Bit 0 corresponds to Port 0, and so on. Interrupt is cleared by register rd_poison_intr_clr, then value propagated to APB clock.
Programming Mode: Dynamic

Bit 18 – RD_POISON_INTR_2 Read transaction poisoning error interrupt for port 2. This register is a APB clock copy (double register synchronizer) of the interrupt asserted when a transaction is poisoned on the corresponding AXI port's read address channel. Bit 0 corresponds to Port 0, and so on. Interrupt is cleared by register rd_poison_intr_clr, then value propagated to APB clock.
Programming Mode: Dynamic

Bit 17 – RD_POISON_INTR_1 Read transaction poisoning error interrupt for port 1. This register is a APB clock copy (double register synchronizer) of the interrupt asserted when a transaction is poisoned on the corresponding AXI port's read address channel. Bit 0 corresponds to Port 0, and so on. Interrupt is cleared by register rd_poison_intr_clr, then value propagated to APB clock.
Programming Mode: Dynamic

Bit 16 – RD_POISON_INTR_0 Read transaction poisoning error interrupt for port 0. This register is a APB clock copy (double register synchronizer) of the interrupt asserted when a transaction is poisoned on the corresponding

AXI port's read address channel. Bit 0 corresponds to Port 0, and so on. Interrupt is cleared by register rd_poison_intr_clr, then value propagated to APB clock.
Programming Mode: Dynamic

Bit 4 – WR_POISON_INTR_4 Write transaction poisoning error interrupt for port 4. This register is a APB clock copy (double register synchronizer) of the interrupt asserted when a transaction is poisoned on the corresponding AXI port's write address channel. Bit 0 corresponds to Port 0, and so on. Interrupt is cleared by register wr_poison_intr_clr, then value propagated to APB clock.
Programming Mode: Dynamic

Bit 3 – WR_POISON_INTR_3 Write transaction poisoning error interrupt for port 3. This register is a APB clock copy (double register synchronizer) of the interrupt asserted when a transaction is poisoned on the corresponding AXI port's write address channel. Bit 0 corresponds to Port 0, and so on. Interrupt is cleared by register wr_poison_intr_clr, then value propagated to APB clock.
Programming Mode: Dynamic

Bit 2 – WR_POISON_INTR_2 Write transaction poisoning error interrupt for port 2. This register is a APB clock copy (double register synchronizer) of the interrupt asserted when a transaction is poisoned on the corresponding AXI port's write address channel. Bit 0 corresponds to Port 0, and so on. Interrupt is cleared by register wr_poison_intr_clr, then value propagated to APB clock.
Programming Mode: Dynamic

Bit 1 – WR_POISON_INTR_1 Write transaction poisoning error interrupt for port 1. This register is a APB clock copy (double register synchronizer) of the interrupt asserted when a transaction is poisoned on the corresponding AXI port's write address channel. Bit 0 corresponds to Port 0, and so on. Interrupt is cleared by register wr_poison_intr_clr, then value propagated to APB clock.
Programming Mode: Dynamic

Bit 0 – WR_POISON_INTR_0 Write transaction poisoning error interrupt for port 0. This register is a APB clock copy (double register synchronizer) of the interrupt asserted when a transaction is poisoned on the corresponding AXI port's write address channel. Bit 0 corresponds to Port 0, and so on. Interrupt is cleared by register wr_poison_intr_clr, then value propagated to APB clock.
Programming Mode: Dynamic

17.6.73 UDDRC Temperature Derate Status Register

Name: UDDRC_DERATESTAT
Offset: 0x3F0

Programming Mode: Dynamic

Bit 2 – RD_PORT_BUSY_2 Indicates if there are outstanding reads for AXI port 2.
Programming Mode: Dynamic

Bit 1 – RD_PORT_BUSY_1 Indicates if there are outstanding reads for AXI port 1.
Programming Mode: Dynamic

Bit 0 – RD_PORT_BUSY_0 Indicates if there are outstanding reads for AXI port 0.
Programming Mode: Dynamic

17.6.75 UDDRC Port Common Configuration Register

Name: UDDRC_PCCFG
Offset: 0x400
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
								BL_EXP_MODE
Access								R/W
Reset								0

Bit	7	6	5	4	3	2	1	0
				PAGEMATCH_LIMIT				GO2CRITICAL_EN
Access				R/W				R/W
Reset				0				0

Bit 8 – BL_EXP_MODE Burst length expansion mode. By default (i.e. bl_exp_mode==0) XPI expands every AXI burst into multiple HIF commands, using the memory burst length as a unit. If set to 1, then XPI will use half of the memory burst length as a unit.
This applies to both reads and writes. When MSTR.data_bus_width==00, setting bl_exp_mode to 1 has no effect.
Functionality is also not supported if Data Channel Interleave is enabled
Programming Mode: Static

Bit 4 – PAGEMATCH_LIMIT Page match four limit. If set to 1, limits the number of consecutive same page DDRC transactions that can be granted by the Port Arbiter to four when Page Match feature is enabled. If set to 0, there is no limit imposed on number of consecutive same page DDRC transactions.
Programming Mode: Static

Bit 0 – GO2CRITICAL_EN If set to 1 (enabled), sets the co_gs_go2critical_wr and co_gs_go2critical_lpr/co_gs_go2critical_hpr signals going to DDRC based on urgent input (awurgent, arurgent) coming from the AXI host. If set to 0 (disabled), the co_gs_go2critical_wr and co_gs_go2critical_lpr/co_gs_go2critical_hpr signals at DDRC are driven to 1b'0.
For uPCTL2, this register field must be set to 0
Programming Mode: Static

17.6.76 UDDRC AXI Port 0 Configuration Read Register

Name: UDDRC_PCFGR_0

	RD_PORT_PRIORITY[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit 14 – RD_PORT_PAGEMATCH_EN If set to 1, enables the Page Match feature. If enabled, once a requesting port is granted, the port is continued to be granted if the following immediate commands are to the same memory page (same bank and same row). See also UDDRC_PCCFG.PAGEMATCH_LIMIT.
Programming Mode: Static

Bit 13 – RD_PORT_URGENT_EN If set to 1, enables the AXI urgent sideband signal (arurgent). When enabled and arurgent is asserted by the host, that port becomes the highest priority and co_gs_go2critical_lpr/ co_gs_go2critical_hpr signal to DDRC is asserted if enabled in PCCFG.go2critical_en register. Note that arurgent signal can be asserted anytime and as long as required which is independent of address handshaking (it is not associated with any particular command).
Programming Mode: Static

Bit 12 – RD_PORT_AGING_EN If set to 1, enables aging function for the read channel of the port.
Programming Mode: Static

Bits 9:0 – RD_PORT_PRIORITY[9:0]
Determines the initial load value of read aging counters. These counters will be parallel loaded after reset, or after each grant to the corresponding port. The aging counters down-count every clock cycle where the port is requesting but not granted. The higher significant 5-bits of the read aging counter sets the priority of the read channel of a given port. Port's priority will increase as the higher significant 5-bits of the counter starts to decrease. When the aging counter becomes 0, the corresponding port channel will have the highest priority level (timeout condition - Priority0). For multi-port configurations, the aging counters cannot be used to set port priorities when external dynamic priority inputs (arqos) are enabled (timeout is still applicable). For single port configurations, the aging counters are only used when they timeout (become 0) to force read-write direction switching. In this case, external dynamic priority input, arqos (for reads only) can still be used to set the DDRC read priority (2 priority levels: low priority read - LPR, high priority read - HPR) on a command by command basis.
Programming Mode: Static
Note: The two LSBs of this register field are tied internally to 2'b00.

17.6.77 UDDRC AXI Port 0 Configuration Write Register

Access								
Reset								

Bit	7	6	5	4	3	2	1	0
					RQOS_MAP_LEVEL1[3:0]			
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bits 21:20 – RQOS_MAP_REGION1[1:0] This bitfield indicates the traffic class of region 1.
Valid values are:
- 0 : LPR
- 1: VPR
- 2: HPR
For dual address queue configurations, region1 maps to the blue address queue.
In this case, valid values are
- 0: LPR
- 1: VPR only
When VPR support is disabled (UDDRC_VPR_EN = 0) and traffic class of region 1 is set to 1 (VPR), VPR traffic is aliased to LPR traffic.
Programming Mode: Quasi-dynamic Group 3

Bits 17:16 – RQOS_MAP_REGION0[1:0] This bitfield indicates the traffic class of region 0.
Valid values are:
- 0: LPR
- 1: VPR
- 2: HPR
For dual address queue configurations, region 0 maps to the blue address queue.
In this case, valid values are:
0: LPR and 1: VPR only.
When VPR support is disabled (UDDRC_VPR_EN = 0) and traffic class of region0 is set to 1 (VPR), VPR traffic is aliased to LPR traffic.
Programming Mode: Quasi-dynamic Group 3

Bits 3:0 – RQOS_MAP_LEVEL1[3:0] Separation level1 indicating the end of region0 mapping; start of region0 is 0.
Possible values for level1 are 0 to 13 (for dual RAQ) or 0 to 14 (for single RAQ) which corresponds to arqos.
Note that for PA, arqos values are used directly as port priorities, where the higher the value corresponds to higher port priority.
All of the map_level* registers must be set to distinct values.

Programming Mode: Quasi-dynamic Group 3

Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bits 25:24 – WQOS_MAP_REGION2[1:0] This bitfield indicates the traffic class of region 2.
Valid values are:
0: NPW, 1: VPW.
When VPW support is disabled (UDDRC_VPW_EN = 0) and traffic class of region 2 is set to 1 (VPW), VPW traffic is aliased to NPW traffic.
Programming Mode: Quasi-dynamic Group 3

Bits 21:20 – WQOS_MAP_REGION1[1:0] This bitfield indicates the traffic class of region 1.
Valid values are:
0: NPW, 1: VPW.
When VPW support is disabled (UDDRC_VPW_EN = 0) and traffic class of region 1 is set to 1 (VPW), VPW traffic is aliased to NPW traffic.
Programming Mode: Quasi-dynamic Group 3

Bits 17:16 – WQOS_MAP_REGION0[1:0] This bitfield indicates the traffic class of region 0.
Valid values are:
0: NPW, 1: VPW.
When VPW support is disabled (UDDRC_VPW_EN = 0) and traffic class of region 0 is set to 1 (VPW), VPW traffic is aliased to NPW traffic.
Programming Mode: Quasi-dynamic Group 3

Bits 11:8 – WQOS_MAP_LEVEL2[3:0] Separation level2 indicating the end of region1 mapping; start of region1 is (level1 + 1). Possible values for level2 are (level1 + 1) to 14 which corresponds to awqos.
Region2 starts from (level2 + 1) up to 15.
Note that for PA, awqos values are used directly as port priorities, where the higher the value corresponds to higher port priority.
All of the map_level* registers must be set to distinct values.
Programming Mode: Quasi-dynamic Group 3

Bits 3:0 – WQOS_MAP_LEVEL1[3:0] Separation level indicating the end of region0 mapping; start of region0 is 0.
Possible values for level1 are 0 to 13 which corresponds to awqos.
Note that for PA, awqos values are used directly as port priorities, where the higher the value corresponds to higher port priority.
All of the map_level* registers must be set to distinct values.
Programming Mode: Quasi-dynamic Group 3

17.6.83 UDDRC AXI Port 1 Configuration Read Register

Name: UDDRC_PCFGR_1
Offset: 0x4B4
Reset: 0x00004000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
		RD_PORT_PAGEMATCH_EN	RD_PORT_URGENT_EN	RD_PORT_AGING_EN			RD_PORT_PRIORITY[9:8]	
Access		R/W	R/W	R/W			R/W	R/W
Reset		1	0	0			0	0

Bit	7	6	5	4	3	2	1	0
	RD_PORT_PRIORITY[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit 14 – RD_PORT_PAGEMATCH_EN If set to 1, enables the Page Match feature. If enabled, once a requesting port is granted, the port is continued to be granted if the following immediate commands are to the same memory page (same bank and same row). See also UDDRC_PCCFG.PAGEMATCH_LIMIT.
Programming Mode: Static

Bit 13 – RD_PORT_URGENT_EN If set to 1, enables the AXI urgent sideband signal (arurgent). When enabled and arurgent is asserted by the host, that port becomes the highest priority and co_gs_go2critical_lpr/co_gs_go2critical_hpr signal to DDRC is asserted if enabled in PCCFG.go2critical_en register. Note that arurgent signal can be asserted anytime and as long as required which is independent of address handshaking (it is not associated with any particular command).
Programming Mode: Static

Bit 12 – RD_PORT_AGING_EN If set to 1, enables aging function for the read channel of the port.
Programming Mode: Static

Bits 9:0 – RD_PORT_PRIORITY[9:0]
Determines the initial load value of read aging counters. These counters will be parallel loaded after reset, or after each grant to the corresponding port. The aging counters down-count every clock cycle where the port is requesting but not granted. The higher significant 5-bits of the read aging counter sets the priority of the read channel of a given port. Port's priority will increase as the higher significant 5-bits of the counter starts to decrease. When the aging counter becomes 0, the corresponding port channel will have the highest priority level (timeout condition - Priority0). For multi-port configurations, the aging counters cannot be used to set port priorities when external dynamic priority inputs (arqos) are enabled (timeout is still applicable). For single port configurations, the aging counters are only used when they timeout (become 0) to force read-write direction switching. In this case, external dynamic priority input, arqos (for reads only) can still be used to set the DDRC read priority (2 priority levels: low priority read - LPR, high priority read - HPR) on a command by command basis.
Programming Mode: Static
Note: The two LSBs of this register field are tied internally to 2'b00.

Bits 21:20 – RQOS_MAP_REGION1[1:0] This bitfield indicates the traffic class of region 1.
Valid values are:
- 0 : LPR
- 1: VPR
- 2: HPR
For dual address queue configurations, region1 maps to the blue address queue.
In this case, valid values are
- 0: LPR
- 1: VPR only
When VPR support is disabled (UDDRC_VPR_EN = 0) and traffic class of region 1 is set to 1 (VPR), VPR traffic is aliased to LPR traffic.
Programming Mode: Quasi-dynamic Group 3

Bits 17:16 – RQOS_MAP_REGION0[1:0] This bitfield indicates the traffic class of region 0.
Valid values are:
- 0: LPR
- 1: VPR
- 2: HPR
For dual address queue configurations, region 0 maps to the blue address queue.
In this case, valid values are:
0: LPR and 1: VPR only.
When VPR support is disabled (UDDRC_VPR_EN = 0) and traffic class of region0 is set to 1 (VPR), VPR traffic is aliased to LPR traffic.
Programming Mode: Quasi-dynamic Group 3

Bits 3:0 – RQOS_MAP_LEVEL1[3:0] Separation level1 indicating the end of region0 mapping; start of region0 is 0.
Possible values for level1 are 0 to 13 (for dual RAQ) or 0 to 14 (for single RAQ) which corresponds to arqos.
Note that for PA, arqos values are used directly as port priorities, where the higher the value corresponds to higher port priority.
All of the map_level* registers must be set to distinct values.

Programming Mode: Quasi-dynamic Group 3

Bits 17:16 – WQOS_MAP_REGION0[1:0] This bitfield indicates the traffic class of region 0.
Valid values are:
0: NPW, 1: VPW.
When VPW support is disabled (UDDRC_VPW_EN = 0) and traffic class of region 0 is set to 1 (VPW), VPW traffic is aliased to NPW traffic.
Programming Mode: Quasi-dynamic Group 3

Bits 11:8 – WQOS_MAP_LEVEL2[3:0] Separation level2 indicating the end of region1 mapping; start of region1 is (level1 + 1). Possible values for level2 are (level1 + 1) to 14 which corresponds to awqos.
Region2 starts from (level2 + 1) up to 15.
Note that for PA, awqos values are used directly as port priorities, where the higher the value corresponds to higher port priority.
All of the map_level* registers must be set to distinct values.
Programming Mode: Quasi-dynamic Group 3

Bits 3:0 – WQOS_MAP_LEVEL1[3:0] Separation level indicating the end of region0 mapping; start of region0 is 0.
Possible values for level1 are 0 to 13 which corresponds to awqos.
Note that for PA, awqos values are used directly as port priorities, where the higher the value corresponds to higher port priority.
All of the map_level* registers must be set to distinct values.
Programming Mode: Quasi-dynamic Group 3

17.6.89 UDDRC AXI Port 1 Write QoS Configuration Register 1

Name: UDDRC_PCFGWQOS1_1
Offset: 0x550
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24

Bits 26:16 – WQOS_MAP_TIMEOUT2[10:0] Specifies the timeout value for write transactions in region 2.
Programming Mode: Quasi-dynamic Group 3

Bits 10:0 – WQOS_MAP_TIMEOUT1[10:0] Specifies the timeout value for write transactions in region 0 and 1.
Programming Mode: Quasi-dynamic Group 3

17.6.90 UDDRC AXI Port 2 Configuration Read Register

Name: UDDRC_PCFGR_2
Offset: 0x564
Reset: 0x00004000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
		RD_PORT_PAGEMATCH_EN	RD_PORT_URGENT_EN	RD_PORT_AGING_EN			RD_PORT_PRIORITY[9:8]	
Access		R/W	R/W	R/W			R/W	R/W
Reset		1	0	0			0	0

Bit	7	6	5	4	3	2	1	0
	RD_PORT_PRIORITY[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit 14 – RD_PORT_PAGEMATCH_EN If set to 1, enables the Page Match feature. If enabled, once a requesting port is granted, the port is continued to be granted if the following immediate commands are to the same memory page (same bank and same row). See also UDDRC_PCCFG.PAGEMATCH_LIMIT.
Programming Mode: Static

Bit 13 – RD_PORT_URGENT_EN If set to 1, enables the AXI urgent sideband signal (arurgent). When enabled and arurgent is asserted by the host, that port becomes the highest priority and co_gs_go2critical_lpr/co_gs_go2critical_hpr signal to DDRC is asserted if enabled in PCCFG.go2critical_en register. Note that arurgent signal can be asserted anytime and as long as required which is independent of address handshaking (it is not associated with any particular command).
Programming Mode: Static

Bit 12 – RD_PORT_AGING_EN If set to 1, enables aging function for the read channel of the port.
Programming Mode: Static

Bits 9:0 – RD_PORT_PRIORITY[9:0]
Determines the initial load value of read aging counters. These counters will be parallel loaded after reset, or after each grant to the corresponding port. The aging counters down-count every clock cycle where the port is requesting but not granted. The higher significant 5-bits of the read aging counter sets the priority of the read channel of a given port. Port's priority will increase as the higher significant 5-bits of the counter starts to decrease. When the aging counter becomes 0, the corresponding port channel will have the highest priority level (timeout condition - Priority0). For multi-port configurations, the aging counters cannot be used to set port priorities when external dynamic priority inputs (arqos) are enabled (timeout is still applicable). For single port configurations, the aging counters are only used when they timeout (become 0) to force read-write direction switching. In this case, external dynamic priority input, arqos (for reads only) can still be used to set the DDRC read priority (2 priority levels: low priority read - LPR, high priority read - HPR) on a command by command basis.
Programming Mode: Static
Note: The two LSBs of this register field are tied internally to 2'b00.

17.6.91 UDDRC AXI Port 2 Configuration Write Register

Name: UDDRC_PCFGW_2

Programming Mode: Dynamic

17.6.93 UDDRC AXI Port 2 Read QoS Configuration Register 0

Name: UDDRC_PCFGQOS0_2
Offset: 0x5F4
Reset: 0x02000E00
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
							RQOS_MAP_REGION2[1:0]	
Access							R/W	R/W
Reset							1	0

Bit	23	22	21	20	19	18	17	16
			RQOS_MAP_REGION1[1:0]				RQOS_MAP_REGION0[1:0]	
Access			R/W	R/W			R/W	R/W
Reset			0	0			0	0

Bit	15	14	13	12	11	10	9	8
					RQOS_MAP_LEVEL2[3:0]			
Access					R/W	R/W	R/W	R/W
Reset					1	1	1	0

Bit	7	6	5	4	3	2	1	0
					RQOS_MAP_LEVEL1[3:0]			
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bits 25:24 – RQOS_MAP_REGION2[1:0] This bitfield indicates the traffic class of region2.
For dual address queue configurations, region2 maps to the red address queue.
Valid values are 1: VPR and 2: HPR only.
When VPR support is disabled (UDDRC_VPR_EN = 0) and traffic class of region2 is set to 1 (VPR), VPR traffic is aliased to LPR traffic.
Programming Mode: Quasi-dynamic Group 3

Bits 21:20 – RQOS_MAP_REGION1[1:0] This bitfield indicates the traffic class of region 1.
Valid values are:
- 0 : LPR
- 1: VPR
- 2: HPR
For dual address queue configurations, region1 maps to the blue address queue.
In this case, valid values are
- 0: LPR
- 1: VPR only
When VPR support is disabled (UDDRC_VPR_EN = 0) and traffic class of region 1 is set to 1 (VPR), VPR traffic is aliased to LPR traffic.
Programming Mode: Quasi-dynamic Group 3

Bits 17:16 – RQOS_MAP_REGION0[1:0] This bitfield indicates the traffic class of region 0.
Valid values are:
- 0: LPR
- 1: VPR
- 2: HPR
For dual address queue configurations, region 0 maps to the blue address queue.
In this case, valid values are:
0: LPR and 1: VPR only.
When VPR support is disabled (UDDRC_VPR_EN = 0) and traffic class of region0 is set to 1 (VPR), VPR traffic is aliased to LPR traffic.

Programming Mode: Quasi-dynamic Group 3

Bits 11:8 – RQOS_MAP_LEVEL2[3:0] Separation level2 indicating the end of region1 mapping; start of region1 is (level1 + 1). Possible values for level2 are (level1 + 1) to 14 which corresponds to arqos.
Region2 starts from (level2 + 1) up to 15.
Note that for PA, arqos values are used directly as port priorities, where the higher the value corresponds to higher port priority.
All of the map_level* registers must be set to distinct values.
Programming Mode: Quasi-dynamic Group 3

Bits 3:0 – RQOS_MAP_LEVEL1[3:0] Separation level1 indicating the end of region0 mapping; start of region0 is 0. Possible values for level1 are 0 to 13 (for dual RAQ) or 0 to 14 (for single RAQ) which corresponds to arqos.
Note that for PA, arqos values are used directly as port priorities, where the higher the value corresponds to higher port priority.
All of the map_level* registers must be set to distinct values.
Programming Mode: Quasi-dynamic Group 3

17.6.94 UDDRC AXI Port 2 Read QoS Configuration Register 1

Name: UDDRC_PCFGQOS1_2

Bits 25:24 – WQOS_MAP_REGION2[1:0] This bitfield indicates the traffic class of region 2.
Valid values are:
0: NPW, 1: VPW.
When VPW support is disabled (UDDRC_VPW_EN = 0) and traffic class of region 2 is set to 1 (VPW), VPW traffic is aliased to NPW traffic.
Programming Mode: Quasi-dynamic Group 3

Bits 21:20 – WQOS_MAP_REGION1[1:0] This bitfield indicates the traffic class of region 1.
Valid values are:
0: NPW, 1: VPW.
When VPW support is disabled (UDDRC_VPW_EN = 0) and traffic class of region 1 is set to 1 (VPW), VPW traffic is aliased to NPW traffic.
Programming Mode: Quasi-dynamic Group 3

Bits 17:16 – WQOS_MAP_REGION0[1:0] This bitfield indicates the traffic class of region 0.
Valid values are:
0: NPW, 1: VPW.
When VPW support is disabled (UDDRC_VPW_EN = 0) and traffic class of region 0 is set to 1 (VPW), VPW traffic is aliased to NPW traffic.
Programming Mode: Quasi-dynamic Group 3

Bits 11:8 – WQOS_MAP_LEVEL2[3:0] Separation level2 indicating the end of region1 mapping; start of region1 is (level1 + 1). Possible values for level2 are (level1 + 1) to 14 which corresponds to awqos.
Region2 starts from (level2 + 1) up to 15.
Note that for PA, awqos values are used directly as port priorities, where the higher the value corresponds to higher port priority.
All of the map_level* registers must be set to distinct values.
Programming Mode: Quasi-dynamic Group 3

Bits 3:0 – WQOS_MAP_LEVEL1[3:0] Separation level indicating the end of region0 mapping; start of region0 is 0.
Possible values for level1 are 0 to 13 which corresponds to awqos.
Note that for PA, awqos values are used directly as port priorities, where the higher the value corresponds to higher port priority.
All of the map_level* registers must be set to distinct values.
Programming Mode: Quasi-dynamic Group 3

17.6.97 UDDRC AXI Port 3 Configuration Read Register

Name: UDDRC_PCFGR_3
Offset: 0x614
Reset: 0x00004000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
		RD_PORT_PAGEMATCH_EN	RD_PORT_URGENT_EN	RD_PORT_AGING_EN			RD_PORT_PRIORITY[9:8]	
Access		R/W	R/W	R/W			R/W	R/W
Reset		1	0	0			0	0

Bit	7	6	5	4	3	2	1	0
	RD_PORT_PRIORITY[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit 14 – RD_PORT_PAGEMATCH_EN If set to 1, enables the Page Match feature. If enabled, once a requesting port is granted, the port is continued to be granted if the following immediate commands are to the same memory page (same bank and same row). See also UDDRC_PCCFG.PAGEMATCH_LIMIT.
Programming Mode: Static

Bit 13 – RD_PORT_URGENT_EN If set to 1, enables the AXI urgent sideband signal (arurgent). When enabled and arurgent is asserted by the host, that port becomes the highest priority and co_gs_go2critical_lpr/ co_gs_go2critical_hpr signal to DDRC is asserted if enabled in PCCFG.go2critical_en register. Note that arurgent signal can be asserted anytime and as long as required which is independent of address handshaking (it is not associated with any particular command).
Programming Mode: Static

Bit 12 – RD_PORT_AGING_EN If set to 1, enables aging function for the read channel of the port.
Programming Mode: Static

Bits 9:0 – RD_PORT_PRIORITY[9:0]
Determines the initial load value of read aging counters. These counters will be parallel loaded after reset, or after each grant to the corresponding port. The aging counters down-count every clock cycle where the port is requesting but not granted. The higher significant 5-bits of the read aging counter sets the priority of the read channel of a given port. Port's priority will increase as the higher significant 5-bits of the counter starts to decrease. When the aging counter becomes 0, the corresponding port channel will have the highest priority level (timeout condition - Priority0). For multi-port configurations, the aging counters cannot be used to set port priorities when external dynamic priority inputs (arqos) are enabled (timeout is still applicable). For single port configurations, the aging counters are only used when they timeout (become 0) to force read-write direction switching. In this case, external dynamic priority input, arqos (for reads only) can still be used to set the DDRC read priority (2 priority levels: low priority read - LPR, high priority read - HPR) on a command by command basis.
Programming Mode: Static
Note: The two LSBs of this register field are tied internally to 2'b00.

17.6.98 UDDRC AXI Port 3 Configuration Write Register

Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bits 21:20 – RQOS_MAP_REGION1[1:0] This bitfield indicates the traffic class of region 1.
Valid values are:
- 0 : LPR
- 1: VPR
- 2: HPR
For dual address queue configurations, region1 maps to the blue address queue.
In this case, valid values are
- 0: LPR
- 1: VPR only
When VPR support is disabled (UDDRC_VPR_EN = 0) and traffic class of region 1 is set to 1 (VPR), VPR traffic is aliased to LPR traffic.
Programming Mode: Quasi-dynamic Group 3

Bits 17:16 – RQOS_MAP_REGION0[1:0] This bitfield indicates the traffic class of region 0.
Valid values are:
- 0: LPR
- 1: VPR
- 2: HPR
For dual address queue configurations, region 0 maps to the blue address queue.
In this case, valid values are:
0: LPR and 1: VPR only.
When VPR support is disabled (UDDRC_VPR_EN = 0) and traffic class of region0 is set to 1 (VPR), VPR traffic is aliased to LPR traffic.
Programming Mode: Quasi-dynamic Group 3

Bits 3:0 – RQOS_MAP_LEVEL1[3:0] Separation level1 indicating the end of region0 mapping; start of region0 is 0.
Possible values for level1 are 0 to 13 (for dual RAQ) or 0 to 14 (for single RAQ) which corresponds to arqos.
Note that for PA, arqos values are used directly as port priorities, where the higher the value corresponds to higher port priority.
All of the map_level* registers must be set to distinct values.

Programming Mode: Quasi-dynamic Group 3

17.6.101 UDDRC AXI Port 3 Read QoS Configuration Register 1

Name: UDDRC_PCFGQOS1_3
Offset: 0x6A8
Reset: 0x00000000

Reset					0	0	0	0

Bits 25:24 – WQOS_MAP_REGION2[1:0] This bitfield indicates the traffic class of region 2.
Valid values are:
0: NPW, 1: VPW.
When VPW support is disabled (UDDRC_VPW_EN = 0) and traffic class of region 2 is set to 1 (VPW), VPW traffic is aliased to NPW traffic.
Programming Mode: Quasi-dynamic Group 3

Bits 21:20 – WQOS_MAP_REGION1[1:0] This bitfield indicates the traffic class of region 1.
Valid values are:
0: NPW, 1: VPW.
When VPW support is disabled (UDDRC_VPW_EN = 0) and traffic class of region 1 is set to 1 (VPW), VPW traffic is aliased to NPW traffic.
Programming Mode: Quasi-dynamic Group 3

Bits 17:16 – WQOS_MAP_REGION0[1:0] This bitfield indicates the traffic class of region 0.
Valid values are:
0: NPW, 1: VPW.
When VPW support is disabled (UDDRC_VPW_EN = 0) and traffic class of region 0 is set to 1 (VPW), VPW traffic is aliased to NPW traffic.
Programming Mode: Quasi-dynamic Group 3

Bits 11:8 – WQOS_MAP_LEVEL2[3:0] Separation level2 indicating the end of region1 mapping; start of region1 is (level1 + 1). Possible values for level2 are (level1 + 1) to 14 which corresponds to awqos.
Region2 starts from (level2 + 1) up to 15.
Note that for PA, awqos values are used directly as port priorities, where the higher the value corresponds to higher port priority.
All of the map_level* registers must be set to distinct values.
Programming Mode: Quasi-dynamic Group 3

Bits 3:0 – WQOS_MAP_LEVEL1[3:0] Separation level indicating the end of region0 mapping; start of region0 is 0. Possible values for level1 are 0 to 13 which corresponds to awqos.
Note that for PA, awqos values are used directly as port priorities, where the higher the value corresponds to higher port priority.
All of the map_level* registers must be set to distinct values.
Programming Mode: Quasi-dynamic Group 3

17.6.103 UDDRC AXI Port 3 Write QoS Configuration Register 1

Programming Mode: Quasi-dynamic Group 3

Bits 10:0 – WQOS_MAP_TIMEOUT1[10:0] Specifies the timeout value for write transactions in region 0 and 1.
Programming Mode: Quasi-dynamic Group 3

17.6.104 UDDRC AXI Port 4 Configuration Read Register

Name: UDDRC_PCFGR_4
Offset: 0x6C4
Reset: 0x00004000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
		RD_PORT_PAGEMATCH_EN	RD_PORT_URGENT_EN	RD_PORT_AGING_EN			RD_PORT_PRIORITY[9:8]	
Access		R/W	R/W	R/W			R/W	R/W
Reset		1	0	0			0	0

Bit	7	6	5	4	3	2	1	0
	RD_PORT_PRIORITY[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit 14 – RD_PORT_PAGEMATCH_EN If set to 1, enables the Page Match feature. If enabled, once a requesting port is granted, the port is continued to be granted if the following immediate commands are to the same memory page (same bank and same row). See also UDDRC_PCCFG.PAGEMATCH_LIMIT.
Programming Mode: Static

Bit 13 – RD_PORT_URGENT_EN If set to 1, enables the AXI urgent sideband signal (arurgent). When enabled and arurgent is asserted by the host, that port becomes the highest priority and co_gs_go2critical_lpr/co_gs_go2critical_hpr signal to DDRC is asserted if enabled in PCCFG.go2critical_en register. Note that arurgent signal can be asserted anytime and as long as required which is independent of address handshaking (it is not associated with any particular command).
Programming Mode: Static

Bit 12 – RD_PORT_AGING_EN If set to 1, enables aging function for the read channel of the port.
Programming Mode: Static

Bits 9:0 – RD_PORT_PRIORITY[9:0]
Determines the initial load value of read aging counters. These counters will be parallel loaded after reset, or after each grant to the corresponding port. The aging counters down-count every clock cycle where the port is requesting but not granted. The higher significant 5-bits of the read aging counter sets the priority of the read channel of a given port. Port's priority will increase as the higher significant 5-bits of the counter starts to decrease. When the aging counter becomes 0, the corresponding port channel will have the highest priority level (timeout condition - Priority0). For multi-port configurations, the aging counters cannot be used to set port priorities when external dynamic priority inputs (arqos) are enabled (timeout is still applicable). For single port configurations, the aging counters are only used when they timeout (become 0) to force read-write direction switching. In this case, external dynamic priority input, arqos (for reads only) can still be used to set the DDRC read priority (2 priority levels: low priority read - LPR, high priority read - HPR) on a command by command basis.
Programming Mode: Static
Note: The two LSBs of this register field are tied internally to 2'b00.

17.6.105 UDDRC AXI Port 4 Configuration Write Register

					RQOS_MAP_LEVEL1[3:0]			
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bits 21:20 – RQOS_MAP_REGION1[1:0] This bitfield indicates the traffic class of region 1.
Valid values are:
- 0 : LPR
- 1: VPR
- 2: HPR
For dual address queue configurations, region1 maps to the blue address queue.
In this case, valid values are
- 0: LPR
- 1: VPR only
When VPR support is disabled (UDDRC_VPR_EN = 0) and traffic class of region 1 is set to 1 (VPR), VPR traffic is aliased to LPR traffic.
Programming Mode: Quasi-dynamic Group 3

Bits 17:16 – RQOS_MAP_REGION0[1:0] This bitfield indicates the traffic class of region 0.
Valid values are:
- 0: LPR
- 1: VPR
- 2: HPR
For dual address queue configurations, region 0 maps to the blue address queue.
In this case, valid values are:
0: LPR and 1: VPR only.
When VPR support is disabled (UDDRC_VPR_EN = 0) and traffic class of region0 is set to 1 (VPR), VPR traffic is aliased to LPR traffic.
Programming Mode: Quasi-dynamic Group 3

Bits 3:0 – RQOS_MAP_LEVEL1[3:0] Separation level1 indicating the end of region0 mapping; start of region0 is 0.
Possible values for level1 are 0 to 13 (for dual RAQ) or 0 to 14 (for single RAQ) which corresponds to arqos.
Note that for PA, arqos values are used directly as port priorities, where the higher the value corresponds to higher port priority.
All of the map_level* registers must be set to distinct values.

Programming Mode: Quasi-dynamic Group 3

Bits 25:24 – WQOS_MAP_REGION2[1:0] This bitfield indicates the traffic class of region 2.
Valid values are:
0: NPW, 1: VPW.
When VPW support is disabled (UDDRC_VPW_EN = 0) and traffic class of region 2 is set to 1 (VPW), VPW traffic is aliased to NPW traffic.
Programming Mode: Quasi-dynamic Group 3

Bits 21:20 – WQOS_MAP_REGION1[1:0] This bitfield indicates the traffic class of region 1.
Valid values are:
0: NPW, 1: VPW.
When VPW support is disabled (UDDRC_VPW_EN = 0) and traffic class of region 1 is set to 1 (VPW), VPW traffic is aliased to NPW traffic.
Programming Mode: Quasi-dynamic Group 3

Bits 17:16 – WQOS_MAP_REGION0[1:0] This bitfield indicates the traffic class of region 0.
Valid values are:
0: NPW, 1: VPW.
When VPW support is disabled (UDDRC_VPW_EN = 0) and traffic class of region 0 is set to 1 (VPW), VPW traffic is aliased to NPW traffic.
Programming Mode: Quasi-dynamic Group 3

Bits 11:8 – WQOS_MAP_LEVEL2[3:0] Separation level2 indicating the end of region1 mapping; start of region1 is (level1 + 1). Possible values for level2 are (level1 + 1) to 14 which corresponds to awqos.
Region2 starts from (level2 + 1) up to 15.
Note that for PA, awqos values are used directly as port priorities, where the higher the value corresponds to higher port priority.
All of the map_level* registers must be set to distinct values.
Programming Mode: Quasi-dynamic Group 3

Bits 3:0 – WQOS_MAP_LEVEL1[3:0] Separation level indicating the end of region0 mapping; start of region0 is 0.
Possible values for level1 are 0 to 13 which corresponds to awqos.
Note that for PA, awqos values are used directly as port priorities, where the higher the value corresponds to higher port priority.
All of the map_level* registers must be set to distinct values.
Programming Mode: Quasi-dynamic Group 3

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 7:0 – NBLOCKS[7:0] Number of blocks for address region 0.
This register determines the total size of the region in multiples of 512 Mbytes. The register value is encoded as number of blocks = nblocks + 1. For example, if register is programmed to 0, region will have 1 block.
Programming Mode: Static

18. DDR/LPDDR Physical Interface (DDR3PHY)

18.1 Description

The DDR/LPDDR DDR3PHY operates the physical interface to JEDEC standard DDR2, DDR3, LPDDR2, LPDDR3 SDRAM memories up to 1066 Mbps data rates.

18.2 Embedded Characteristics

- Compatible with JEDEC Standard DDR2/DDR3/DDR3L/LPDDR2/LPDDR3 SDRAMs
- Operating Range from 100 MHz (200 Mbps) to 533 MHz (1066 Mbps) in DDR2/DDR3/LPDDR2/LPDDR3 Modes
- Operating Range from 0 to 200 MHz in Mobile DDR Mode
- x16 External Data Bus Width
- Programmable Output and ODT (On Die Termination) Impedance with Dynamic PVT Compensation
- Embedded Dynamic Drift Detection in the PHY to facilitate Dynamic Drift Compensation with the Controller
- Host and Client DLLs used for Precise Timing Management
- Lane-based Architecture (Byte Lane, Command Lane)

18.2.1 Supported PHY Data Rates

Table 18-1. Supported Modes and Data Rates

Memory Type	PHY Maximum Speed	Unit
DDR2	1066	Mbps
DDR3	1066	
DDR3L	1066	
LPDDR2	1066	
LPDDR3	1066	

18.2.2 Applicable Standards

The following JEDEC standards are applicable:

- JESD8-15 JEDEC Stub Series Terminated Logic for 1.8V (SSTL_18) Specification
- JESD79-2 JEDEC DDR2 SDRAM Specification
- JESD79-3 JEDEC DDR3 SDRAM Specification
- JESD209-2 JEDEC LPDDR2 SDRAM Specification
- JESD209-3 JEDEC LPDDR3 SDRAM Specification

18.3 Functional Description

18.3.1 Byte Lane PHY

The external memory components are designed to support byte lanes for optimal system timing. The partitioning of the data word into discrete byte lanes allows pin-to-pin skew to be managed across a much smaller group of signals than would typically be required. This eases signal track topology matching in the package and PCB environments.

The SDRAM contains data strobes associated with each 8 bits of data and there is a timing skew allowance between the main clock signal to the SDRAM and its data strobe inputs during a Write command (tDQSS):

- 8-bit memory components provide a single DQS.

- 16-bit memory components provide two DQSs, one for each 8 bits.

A byte lane consists of the following I/O slots:

- 8 data bits (D0-D7)
- Data strobe bits (DQS/DQSN)
- 1 data mask bit (DQM)

The ITMs (Interface Timing Modules) provide a mechanism for monitoring read timing drift, which can be used to adjust timing to maintain optimum system margins. Drift analysis and compensation are performed by the controller on a per-byte lane basis. Read DQS recognition and drift compensation are described further in the section “Universal DDR Memory Controller (UDDRC)”. The ITM components contain the functions to monitor DQS drift and permit timing adjustment; the controller provides the analysis and control for these functions. These functions operate dynamically for each data bit of every user-issued Read command. There are no overhead penalties in terms of channel bandwidth or utilization incurred by the use of these functions.

The memory interface (PHY) architecture is based on the concept of independent, but related, signal groups to provide the highest level of system timing performance. In order to maintain robust system timing, all clock and data signals relevant to a byte lane remain within that byte lane. These signals are not shared between other byte lanes or between a byte lane and a command lane.

A DLL macrocell consisting of a host DLL and two client DLLs (mirror delay lines) is used at each byte lane to facilitate optimal PHY timing for drive and capture of DDR data streams, and allows the lanes to be independent. The host DLL section provides outputs for DDR data stream creation to the SDRAMs and acts as a reference for the client delay line sections. The client delay line sections translate the incoming DQS/DQS_b into the center of the read data eye to maximize read system timing margins.

The user can fine-tune the DQS and DQ signal relationships to maximize the read system timing margin. The DLL includes adjustability of the client delay lines for the DQS and DQS_b signals, which provide byte-wide timing adjustments. The ITMs include adjustability of the read DQS/DQS_b strobe timing, which provides byte-wide timing adjustments. The ITMs include adjustability of the read DQ signal timing, which provides per-bit timing adjustability. To enable lane-independent timing adjustments, DLL adjustment bits are provided by the controller per byte lane, and ITM adjustment bits are provided per bit.

The DDR-specific SSTL I/Os include programmable ODT and output impedance selection. The ODT and output impedances can be dynamically calibrated to compensate for variations in voltage and temperature.

The ODT feature can be disabled by the controller. When ODT is enabled by the controller, the SSTL I/O automatically enables its internal ODT circuitry when in Input mode and disables this circuitry when in Output mode. The initial programming and subsequent calibration of the ODT and output impedance can be triggered to calibrate the ODT and output impedance values at the I/Os based on the desired impedance value when compared to a precision external resistor.

18.3.2 Programming Model

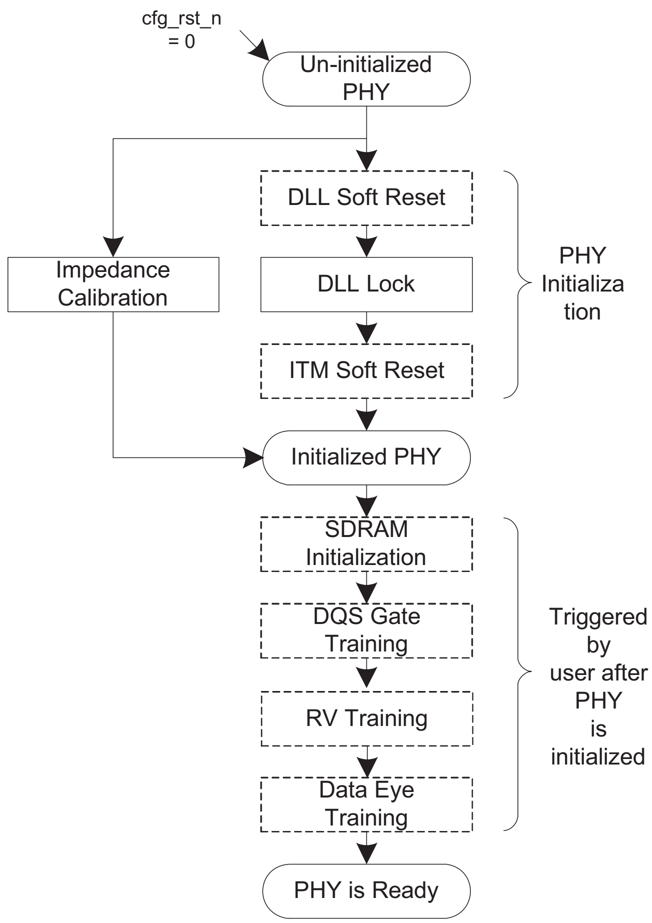
18.3.2.1 Initialization

The initialization sequence has two phases. The first phase happens automatically at reset and is as follows:

1. Before and during configuration reset (i.e. if cfg_rst_n is asserted), the PHY is un-initialized and remains in this state until the reset is de-asserted.
2. At reset de-assertion, the PHY moves into the DLL initialization (lock) phase. This phase may be bypassed at any time by writing a '1' to the DLL initialization bypass register bit (DDR3PHY_PIR.LOCKBYP).
3. In parallel to DLL initialization, the impedance calibration phase also starts at reset de-assertion. This phase can also be bypassed by writing a '1' to the impedance calibration bypass register bit (DDR3PHY_PIR.ZCALBYP).
4. If the PHY initialization sequence was triggered by the user, a soft reset may optionally be selected to be issued to the ITMs. Initialization that is automatically triggered on reset does not issue a soft reset to the ITMs because the components have already been reset by the main reset.
5. Once the DLL initialization and impedance calibration phases are done and after the ITMs are reset, the PHY is initialized. Note that if these phases were bypassed, it is up to the user to perform them using software, or to trigger them at a later time before the PHY can be used.

The following figure shows a high-level illustration of the PHY initialization sequence.

Figure 18-1. DDR3PHY Initialization Flow



The above figure shows the timing diagram for the first phase of PHY initialization which happens automatically after reset is de-asserted.

The DLL soft reset and ITM soft reset are executed only when the first phase is triggered by the user through the PHY Initialization register (DDR3PHY_PIR).

The second initialization phase starts after the PHY is initialized. Each step of this phase is triggered by the user or memory controller:

1. The user or memory controller performs SDRAM initialization sequence. The DRAM mode registers and necessary timing parameters must first be programmed before triggering SDRAM initialization.
2. After the SDRAM is initialized, the user or memory controller performs DQS gate training ("Built-in DQS Gate Training"). The SDRAM must be initialized before triggering DQS gate training.
3. The user or memory controller performs read data valid training.
4. The user or memory controller performs read data eye training.
5. The PHY is now ready for SDRAM read/write accesses.

18.3.2.2 SDRAM Initialization

Important: The PHY registers, SDRAM mode registers, and equivalent register fields inside the memory controller (UDDRC) must be uniformly programmed. Mismatches between the register fields can cause transaction failures. Verify all register fields are consistently programmed before starting any SDRAM transactions.

Prior to normal operation, DDR SDRAMs must be initialized. The PHY has a built-in SDRAM initialization routine that may be triggered by software or memory controller by writing to DDR3PHY_PIR. The initialization routine built into the PHY is generic and does not require any knowledge of the type or configuration of external SDRAMs to be properly executed. The routine is designed with the relevant JEDEC specifications for the fastest and slowest SDRAMs supported by the PHY to result in a universal initialization sequence. This generic sequence is applied to DDR3, DDR2, LPDDR3 and LPDDR2 SDRAMs during the SDRAM initialization sequence. Refer to "SDRAM Initialization Sequence" in the section "Universal DDR Memory Controller (UDDRC)".

18.3.3 PHY Registers

The PHY has registers that are used to configure, control or provide status of certain features of the PHY. The user accesses these registers using the configuration port write and read commands.

All registers are 32 bits wide. For reserved register addresses or reserved register bits, writes have no effect and reads return 0. The following sections describe the PHY registers in detail. Unless specified otherwise, control register bits are assumed active-high.

18.4 Register Summary

Offset	Name	Bit Pos.	7	6	5	4	3	2	1	0

18.4.1 DDR3PHY PHY Initialization Register

Name: DDR3PHY_PIR
Offset: 0x04
Reset: 0x00000000
Property: Read/Write

PHY Initialization Register is used to configure and control the initialization of the PHY. This includes the triggering of certain initialization routines, as well as the reset of the PHY and/or the DLLs used in the PHY. Any configuration register write that sets the PIR[INIT] register bit will trigger initialization as selected by the other PIR register bits. The completion status of this initialization can be checked by polling the PHY General Status Register (PGSR). Note that PGSR0[IDONE] is not cleared immediately after PIR[INIT] is set, and therefore software must wait a minimum of 10 configuration clock cycles from when PIR[INIT] is set to when it starts polling for PGSR[IDONE].

Bit	31	30	29	28	27	26	25	24
	INITBYP	ZCALBYP	LOCKBYP	CLRSR				
Access	R/W	R/W	R/W	R/W				
Reset	0	0	0	0				

Bit	23	22	21	20	19	18	17	16
						CTLDINIT	DLLBYP	ICPC
Access						R/W	R/W	R/W
Reset						0	0	0

Bit	15	14	13	12	11	10	9	8
								RVTRN
Access								R/W
Reset								0

Bit	7	6	5	4	3	2	1	0
	QSTRN	DRAMINIT	DRAMRST	ITMSRST	ZCAL	DLLLOCK	DLLSRST	INIT
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit 31 – INITBYP Initialization Bypass
Bypasses or stops, if set, all initialization routines currently running, including PHY initialization, DRAM initialization, and PHY training. Initialization may be triggered manually using INIT and the other relevant bits of the PIR register. This bit is self-clearing.

Bit 30 – ZCALBYP Impedance Calibration Bypass
Bypasses or stops, if set, impedance calibration of all ZQ control blocks that automatically triggers after reset. Impedance calibration may be triggered manually using INIT and ZCAL bits of the PIR register. This bit is self-clearing.

Bit 29 – LOCKBYP DLL Lock Bypass
Bypasses or stops, if set, the waiting of DLLs to lock. DLL lock wait is automatically triggers after reset. DLL lock wait may be triggered manually using INIT and DLLLOCK bits of the PIR register. This bit is self-clearing.

Bit 28 – CLRSR Clear Status Registers
Writing 1 to this bit does the following:
- Auto-clears itself (PIR.CLRSR). This means reads to PIR.CLRSR will return 0.
- Clears the DXnGSR0 bits for DTDONE, DTERR, DTIERR
- Clears the PGSR.DFTERR and DXnGSR1.DFTERR bits

This bit is primarily for debug purposes and is typically not needed during normal functional operation. It can be used when PGSR.IDONE=1, to manually clear the PGSR status bits, however, the PGSR status bits (except for the DFTRR and TQ bits) are automatically cleared by starting a new init process.
The bit can also be used to manually clear the DXnGSR status bits, however, starting a new data training process automatically clears the DXnGSR status bits.

Bit 18 – CTLDINIT Controller DRAM Initialization
Indicates if set that DRAM initialization will be performed by the controller. Otherwise if not set it indicates that DRAM initialization will be performed using the built-in initialization sequence or using software through the configuration port.

Bit 17 – DLLBYP DLL Bypass
A setting of 1 on this bit will put all PHY DLLs in Bypass mode. A bypassed DLL is also powered down (disabled).
Note: Ensure that the minimum requirements for DLL bypass and DLL reset are observed while asserting this bit.

Bit 16 – ICPC Initialization Complete Pin Configuration
Specifies how the DFI 2.1 initialization complete output pin should be used to indicate the status of initialization.

Value	Description
0	Asserted after PHY initialization (DLL locking and impedance calibration) is complete.
1	Asserted after PHY initialization is complete and the triggered the PUBL initialization (DRAM initialization, data training, or initialization trigger with no selected initialization) is complete.

Bit 8 – RVTRN RV Training
Read DQS Gate Training (QSTRN) and RV Training (RVTRN) should normally be run together. It is expected RVTRN is normally be set whenever PIR.QSTRN is set.
If RVTRN=1 and PIR.QSTRN=0, when PIR.INIT=1 (triggering the init process) the read DQS gate training algorithm will still be run (as if PIR.QSTRN were actually set to 1).
If it is necessary to run only RV training stand-alone, with no read DQS gate training, you can prevent the read DQS gate training from running by setting PGCR.LBGDQS=1 (see 18.4.2. DDR3PHY_PGCR).
Note: RV Training cannot use Multi-Purpose Register (MPR) and must use the user data programmed in DTDR0-1.

Bit 7 – QSTRN Read DQS Training
Executes a PUBL training routine to determine the optimum position of the read data DQS strobe for maximum system timing margins.

Bit 6 – DRAMINIT DRAM Initialization
Executes the DRAM initialization sequence.

Bit 5 – DRAMRST DRAM Reset (DDR3 Only)
Issues a reset to the DRAM (by driving the DRAM reset pin low) and wait 200 µs. This can be triggered in isolation or with the full DRAM initialization (DRAMINIT). For the latter case, the reset is issued and 200 µs is waited before starting the full initialization sequence.

Bit 4 – ITMSRST Interface Timing Module Soft Reset
Soft resets the interface timing modules for the data and data strobes, i.e., it asserts the ITM soft reset (srstb) signal.

Bit 3 – ZCAL Impedance Calibrate
Performs PHY impedance calibration.

Bit 2 – DLLLOCK DLL Lock
Waits for the PHY DLLs to lock.

Bit 1 – DLLSRST DLL Soft Rest
Soft resets all PHY DLLs by driving the DLL soft reset pin.
- Requires that ctl_clk be toggling for the DLL soft reset signal to be output from the DLL. If ctl_clk (AC DLL's cclk_0) is not guaranteed to be toggling, it is recommended to use the manual DLL soft reset ACDLLCR[DLLSRST], not PIR[DLLSRST].
- Ensure that the minimum requirements for DLL bypass and DLL reset are observed while asserting this bit.

Bit 0 – INIT Initialization Trigger
A write of '1' to this bit triggers the DDR system initialization, including PHY initialization, DRAM initialization, and PHY training. The exact initialization steps to be executes are specified in bits 1 to 6 of this register. A bit setting of

1 means the step will be executed as part of the initialization sequence, while a setting of ‘0’ means the step will be bypassed. The initialization trigger bit is self-clearing.

18.4.2 DDR3PHY PHY General Configuration Register

Name: DDR3PHY_PGCR
Offset: 0x08
Reset: 0x01BC2E04
Property: Read/Write

This register is used for miscellaneous PHY configurations such as PHY type, DQS gating configuration, and DQS drift compensation.

Bit	31	30	29	28	27	26	25	24
	LBMODE	LBGDQS	LBDQSS	RFSHDT[3:0]				PDDISDX
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	1

Bit	23	22	21	20	19	18	17	16

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	1	0	0

Bit 31 – LBMODE Loopback Mode
Indicates if set that the PHY/PUBL is in Loopback mode.

Bit 30 – LBGDQS Loopback DQS Gating
Selects the DQS gating mode that should be used when the PHY is in Loopback mode, including BIST Loopback mode.
Note: When PGCR.LBGDQS=0, PIR.QSTRN should not be run prior to running BIST DATX8 loopback.

Value	Description
0	DQS gate training will be triggered on the PUBL.
1	DQS gate is set manually using software.

Bit 29 – LBDQSS Loopback DQS Shift
Selects how the read DQS is shifted during loopback to ensure that the read DQS is centered into the read data eye.

Value	Description
0	PUBL sets the read DQS delay to 0, DQS is already shifted 90 degrees by write path.
1	The read DQS shift is set manually through software.

Bits 28:25 – RFSHDT[3:0] Refresh During Training
A non-zero value specifies that a burst of refreshes equal to the number specified in this field should be sent to the SDRAM after training each rank except the last rank.

Bit 24 – PDDISDX Power Down Disabled Byte
Indicates if set that the DLL and I/Os of a disabled byte should be powered down.

Bits 23:22 – ZCKSEL[1:0] Impedance Clock Divider Select
Selects the divide ratio for the clock used by the impedance control logic. The source clock for the divider is the configuration port clock signal (cfg_clk or pclk), depending on which configuration port type used.

Value	Description
00	Divide by 2
01	Divide by 8
10	Divide by 32
11	Divide by 64

Bits 21:18 – RANKEN[3:0] Rank Enable
Specifies the ranks that are enabled for data training. Bit 0 controls rank 0, bit 1 controls rank 1, bit 2 controls rank 2, and bit 3 controls rank 3. Setting the bit to ‘1’ enables the rank, and setting it to ‘0’ disables the rank.

Bits 17:16 – IODDRM[1:0] I/O DDR Mode (D3F I/O Only)
Selects the DDR mode for the I/Os.

Bit 15 – IOLB I/O Loop-Back Select
Selects where, inside the I/O, the signal loopback happens. Not applicable to D3A I/Os.

Value	Description
0	Loopback is after output buffer, output enable must be asserted.
1	Loopback is before output buffer, output enable is don’t care.

Bit 14 – CKINV CK Invert
Specifies if set that CK/CK# should be inverted. Otherwise CK/CK# toggles with normal polarity.

Bits 13:12 – CKDV[1:0] CK Disable Value
Specifies the static value that should be driven on CK/CK# pair(s) when the pair(s) is disabled. CKDV[0] specifies the value for CK and CKDV[1] specifies the value for CK#.

Bits 11:9 – CKEN[2:0] CK Enable
Controls whether the CK going to the SDRAM is enabled (toggling) or disabled (static value defined by CKDV). One bit for each of the three CK pairs.

Bits 8:5 – DTOSEL[3:0] Digital Test Output Select
Selects the PHY digital test output that should be driven onto PHY digital test output (phy_dto) pin.

Value	Description
0000	DATX8 0 DLL digital test output
0001	DATX8 1 DLL digital test output
0010	DATX8 2 DLL digital test output
0011	DATX8 3 DLL digital test output
0100	DATX8 4 DLL digital test output
0101	DATX8 5 DLL digital test output
0110	DATX8 6 DLL digital test output
0111	DATX8 7 DLL digital test output
1000	DATX8 8 DLL digital test output
1001	AC DLL digital test output
1010 – 0111	Reserved

Bits 4:3 – DFTLMT[1:0] DQS Drift Limit
Specifies the expected limit of drift on read data strobes. A drift of this value or greater is reported as a drift error through the host port error flag.
Note: Although reported through the error flag, this is not an error requiring any action. It is simply an indicator that the drift is greater than expected.

Value	Description
00	No limit (no error reported)
01	90° drift
10	180° drift
11	270° or more drift

Bit 2 – DFTCMP DQS Drift Compensation
Enables or disables DQS drift compensation. By default, drift compensation is enabled. Drift compensation is not supported under any of the following situations:
- LPDDR2/3 (DCR.DDRMD set to LPDDR2)
- Burst length 2 (MR0.BL set to burst length of 2)
- Read DQS gating using passive windowing (PGCR.DQSCFG set to passive windowing)

Drift compensation must be set to disabled if any of the above are set.

Value	Description
0	Disables data strobe drift compensation.
1	Enables data strobe drift compensation.

Bit 1 – DQSCFG DQS Gating Configuration
Selects one of the two DQS gating schemes.
Note: Passive windowing must be used for LPDDR2/3.

Value	Description
0	DQS gating is shut off using the rising edge of DQS_b (Active Windowing mode).
1	DQS gating blankets the whole burst (Passive Windowing mode).

Bit 0 – ITMDMD ITM DDR Mode
Selects whether ITMS uses DQS and DQS# or only DQS.
Note: The correct setting when using DDR is 1 because neither uses DQS#.

Value	Description
0	ITMS uses DQS and DQS#.
1	ITMS uses DQS only.

18.4.3 DDR3PHY PHY General Status Register

Name: DDR3PHY_PGSR
Offset: 0x0C
Reset: 0x00000000
Property: Read-only

This is a general status register for the PHY. It indicates, among other things, whether data training is done.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
							RVEIRR	RVERR
Access							R	R
Reset							0	0

Bit	7	6	5	4	3	2	1	0
	DFTERR	DTIERR	DTERR	DTDONE	DIDONE	ZCDONE	DLDONE	IDONE
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit 9 – RVEIRR Read Valid Training Intermittent Error
If set, indicates that there was an intermittent error during read valid training, such as a pass was followed by a fail then followed by another pass.

Bit 8 – RVERR Read Valid Training Error
If set, indicates that a valid read valid placement could not be found during read valid training.

Bit 7 – DFTERR DQS Drift Error
If set, indicates that at least one of the read data strobes has drifted by more than or equal to the drift limit set in the PHY General Configuration Register (PGCR).

Bit 6 – DTIERR DQS Gate Training Intermittent Error
If set, indicates that there was an intermittent error during DQS gate training, such as a pass was followed by a fail then followed by another pass.

Bit 5 – DTERR DQS GateTraining Error
If set, indicates that a valid DQS gating window could not be found during DQS gate training.

Bit 4 – DTDONE Data Training Done
Indicates, if set, that the PHY has finished doing data training.

Bit 3 – DIDONE DRAM Initialization Done
Indicates if set that DRAM initialization has completed.

Bit 2 – ZCDONE Impedance Calibration Done
Indicates if set that impedance calibration has completed.

Bit 1 – DLDONE DLL Lock Done
Indicates if set that DLL locking has completed.

Bit 0 – IDONE Initialization Done
Indicates if set that the DDR system initialization has completed. This bit is set after all the selected initialization routines in PIR register have completed.

18.4.4 DDR3PHY DLL General Control Register

Name: DDR3PHY_DLLGCR
Offset: 0x10
Reset: 0x00000000
Property: Read/Write

The DLLGCR register provides miscellaneous global configuration and trimming of all the DLLs used in the AC and DATX8 macros, including DLL test modes. Some fields of this register have different default values depending on the technology process. Similarly, some register fields are reserved for other processes.

Bit	31	30	29	28	27	26	25	24
			LOCKDET	FDTRM_SL[1:0]		SBIAS[5:3]		
Access			R/W	R/W	R/W	R/W	R/W	R/W

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	DTC[1:0]		TESTEN	IPUMP[2:0]			DRES[1:0]	
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit 29 – LOCKDET Host Lock Detector Enable
This field is only valid for a few processes. It is reserved for all other processes.

Bits 28:27 – FDTRM_SL[1:0] Client Bypass Fixed Delay Trim

Value	Description
`00`	Nominal delay
`01`	Nominal delay – 10%
`10`	Nominal delay + 10%
`11`	Nominal delay + 20%

Bits 26:24 – SBIAS[5:3] Client Bias Trim
Used to trim the bias for the client DLL.

Bit 23 – BPS200 Bypass Mode Frequency Range

Value	Description
`0`	0 to 100 MHz
`1`	0 to 200 MHz

Bits 22:20 – SBIAS[2:0] Client Bias Trim
Used to trim the bias for the client DLL.

Bits 19:12 – MBIAS[7:0] Host Bias Trim
Used to trim the bias for the host DLL.

Bit 11 – TESTSW Test Switch
Selects the test signals of either the host DLL, set to 0, or the client DLL, set to 1.

Bits 10:9 – ATC[1:0] Analog Test Control
Selects the analog signal to be output on the DLL analog test output (test_out_a) when TESTEN is high (Output is Vss when TESTEN is low). The test output either comes from the host DLL or the client DLL, depending on the setting of the test switch (TESTSW). Both host DLL and client DLL output similar analog test signals.

Value	Description
00	Replica bias output for PMOS (Vbp)
01	Replica bias output for NMOS (Vbn)
10	Filter output (Vc)
11	Vdd

Bits 8:6 – DTC[2:0] Digital Test Control
Selects the digital signal to be output on the DLL digital test output (test_out_d[1]) when TESTEN is high (Output is '0' when TESTEN is low).

Value	Description
	For Host DLL (TESTSW = 0):
000	0 output clock (clk_0)
001	90 output clock (clk_90)
010	180 output clock (clk_180)
011	270 output clock (clk_270)
100	360 internal clock (clk_360_int)
101	Speed-up pulse (spdup)
110	Slow-down pulse (slwdn)
111	0 MCTL logic clock (cclk_0)
	For Client DLL (TESTSW = 1):
000	Input DQS strobe (dqs)
001	Input clock reference (clk_90_in)
010	Internal feedback clock (clk_0_out)
011	90 output DQS_b strobe (dqsb_90)
100	90 output DQS strobe (dqs_90)
111	Auto-lock enable signal

Bit 5 – TESTEN Test Enable
Enables digital and analog test outputs selected by DTC and ATC respectively.

Bits 4:2 – IPUMP[2:0] Charge Pump Current Trim
Used to trim charge pump current.

Value	Description
000	Maximum current
100	Minimum current

Bits 1:0 – DRES[1:0] Delta Resistor Trim
Used to trim reference current versus resistor value variation.
Note: For a few processes this field is reserved and is not used by the DLL.

Value	Description
00	Rnom
01	Rnom - 20%
1x	Rnom + 20%

18.4.5 DDR3PHY AC DLL Control Register

Name: DDR3PHY_ACDLLCR
Offset: 0x14
Reset: 0x40000000
Property: Read/Write

AC DLL Control Register is used to control the DLL on the address/command lane.

Bit	31	30	29	28	27	26	25	24
	DLLDIS	DLLSRST						
Access	R/W	R/W						
Reset	0	1						

Bit	23	22	21	20	19	18	17	16
						ATESTEN		
Access						R/W		
Reset						0		

Bit	15	14	13	12	11	10	9	8
					MFWDLY[2:0]			MFBDLY[2]
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bit	7	6	5	4	3	2	1	0
	MFBDLY[1:0]							
Access	R/W	R/W						
Reset	0	0						

Bit 31 – DLLDIS DLL Disable
A disabled DLL is bypassed. Default ('0') is DLL enabled.

Bit 30 – DLLSRST DLL Soft Rest
Soft resets the AC DLL by driving the DLL soft reset pin.

Bit 18 – ATESTEN Analog Test Enable
Enables the analog test signal to be output on the DLL analog test output (test_out_a). The DLL analog test output is tri-stated when this bit is '0'.

Bits 11:9 – MFWDLY[2:0] Host Feed-Forward Delay Trim
Used to trim the delay in the host DLL feedforward path.

Value	Description
000	Minimum delay
111	Maximum delay

Bits 8:6 – MFBDLY[2:0] Host Feed-Back Delay Trim
Used to trim the delay in the host DLL feedback path.

Value	Description
000	Minimum delay
111	Maximum delay

18.4.6 DDR3PHY PHY Timing Register 0

Name: DDR3PHY_PTR0
Offset: 0x18
Reset: 0x0022AF9B
Property: Read/Write

The PHY Timing Register is used to program different timing parameters used by the PUBL logic.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16

Reset	1	0	0	1	1	0	1	1

Bits 21:18 – tITMSRST[3:0] ITM Soft Reset Time
Number of configuration clock cycles that the ITM soft reset pin must remain asserted when the soft reset is applied to the ITMs. This must correspond to a value that is equal to or more than 8 controller clock cycles. Default value corresponds to 8 controller clock cycles.

Bits 17:6 – tDLLLOCK[11:0] DLL Lock Time
Number of configuration clock cycles for the DLL to stabilize and lock, i.e. number of clock cycles from when the DLL reset pin is de-asserted to when the DLL has locked and is ready for use. Default value corresponds to 5.12 μs at 533 MHz.

Bits 5:0 – tDLLSRST[5:0] DLL Soft Reset Time
Number of configuration clock cycles that the DLL soft reset pin must remain asserted when the soft reset is triggered through the PHY Initialization Register (PIR). This must correspond to a value that is equal to or more than 50 ns or 8 controller clock cycles, whichever is bigger. Default value corresponds to 50 ns at 533 MHz.

18.4.7 DDR3PHY PHY Timing Register 1

Name: DDR3PHY_PTR1
Offset: 0x1C
Reset: 0x0604111D
Property: Read/Write

Bit	31	30	29	28	27	26	25	24

Reset	0	0	0	1	1	1	0	1

Bits 26:19 – tDINIT1[7:0] DRAM Initialization Time 1
DRAM initialization time corresponding to the following:
DDR3 = CKE high time to first command (tRFC +10 ns or 5 tCK, whichever value is larger)
DDR2 = CKE high time to first command (400 ns)
DDR = CKE high time to first command (400 ns or 1 tCK)
LPDDR2 = CKE low time with power and clock stable (100 ns)
LPDDR3 = CKE low time with power and clock stable (100 ns)
Default value corresponds to DDR3 360 ns at 533 MHz

Bits 18:0 – tDINIT0[18:0] DRAM Initialization Time 0
DRAM initialization time corresponding to the following:
DDR3 = CKE low time with power and clock stable (500 μs)
DDR2 = CKE low time with power and clock stable (200 μs)
LPDDR2 = CKE high time to first command (200 μs)
LPDDR3 = CKE high time to first command (200 μs)
Default value corresponds to DDR3 500 μs at 533 MHz.

18.4.8 DDR3PHY PHY Timing Register 2

Name: DDR3PHY_PTR2
Offset: 0x20
Reset: 0x042DA072
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
						tDINIT3[9:7]		
Access						R/W	R/W	R/W
Reset						1	0	0
Bit	**23**	**22**	**21**	**20**	**19**	**18**	**17**	**16**
	tDINIT3[6:0]							tDINIT2[16]
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	1	0	1	1	0	1
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**
	tDINIT2[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	1	0	1	0	0	0	0	0
Bit	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	tDINIT2[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	1	1	1	0	0	1	0

Bits 26:17 – tDINIT3[9:0] DRAM Initialization Time 3
DRAM initialization time corresponding to the following:
LPDDR2 = Time from ZQ initialization command to first command (1 μs)
LPDDR3 = Time from ZQ initialization command to first command (1 μs)
Default value corresponds to the LPDDR2/3 1 μs at 533 MHz.

Bits 16:0 – tDINIT2[16:0] DRAM Initialization Time 2
DRAM initialization time corresponding to the following:
DDR3 = Reset low time (200 μs on power-up or 100 ns after power-up)
LPDDR2 = Time from reset command to end of auto initialization (1 μs + 10 μs = 11 μs)
LPDDR3 = Time from reset command to end of auto initialization (11 μs)
Default value corresponds to DDR3 200 μs at 533 MHz.

18.4.9 DDR3PHY AC I/O Configuration Register

Name: DDR3PHY_ACIOCR
Offset: 0x24
Reset: 0x33C03812
Property: Read/Write

The AC I/O Configuration Register is used to control output enables, on-die termination enables, and power-down enables for SSTL I/Os for all address/command signals going to the SDRAM, including the SDRAM clock (CK).

For D3A I/Os, the IOM register bits connect to the I/O IDDQ pins. Furthermore, the I/O power-down register bits (PDD, PDR, and PD) fields have no relevance for D3A I/Os.

Bit	31	30	29	28	27	26	25	24
	ACSR[1:0]		RSTIOM	RSTPDR	RSTPDD	RSTODT	RANKPDR[3:2]

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	1	1	1	0	0	0

Bit	7	6	5	4	3	2	1	0
	CKODT[2:0]			ACPDR	ACPDD	ACODT	ACOE	ACIOM
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	1	0	0	1	0

Bits 31:30 – ACSR[1:0] Address/Command Slew Rate
Selects slew rate of the I/O for all address and command pins.

Bit 29 – RSTIOM SDRAM Reset I/O Mode
Selects SSTL mode (when set to 0) or CMOS mode (when set to 1) of the I/O for SDRAM Reset.

Bit 28 – RSTPDR SDRAM Reset Power Down Receiver
Powers down, when set, the input receiver on the I/O for SDRAM RST# pin.

Bit 27 – RSTPDD SDRAM Reset Power Down Driver
Powers down, when set, the output driver on the I/O for SDRAM RST# pin.

Bit 26 – RSTODT SDRAM Reset On-Die Termination
Enables, when set, the on-die termination on the I/O for SDRAM RST# pin.

Bits 25:22 – RANKPDR[3:0] Rank Power Down Receiver
Powers down, when set, the input receiver on the I/O
CKE[3:0], ODT[3:0], and CS#[3:0] pins. RANKPDR[0] controls the power down for CKE[0], ODT[0], and CS#[0], RANKPDR[1] controls the power down for CKE[1], ODT[1], and CS#[1], and so on.

Bits 21:18 – CSPDD[3:0] CS# Power Down Driver
Powers down, when set, the output driver on the I/O for CS#[3:0] pins. PDD[0] controls the power down for CS#[0], PDD[1] controls the power down for CS#[1], and so on. CKE and ODT driver power down is controlled by DSGCR register.

Bits 17:14 – RANKODT[3:0] Rank On-Die Termination
Enables, when set, the on-die termination on the I/O for CKE[3:0], ODT[3:0], and CS#[3:0] pins. RANKODT[0] controls the on-die termination for CKE[0], ODT[0], and CS#[0], RANKODT[1] controls the on-die termination for CKE[1], ODT[1], and CS#[1], and so on.

Bits 13:11 – CKPDR[2:0] CK Power Down Receiver
Powers down, when set, the input receiver on the I/O for CK[0], CK[1], and CK[2] pins, respectively.

Bits 10:8 – CKPDD[2:0] CK Power Down Driver
Powers down, when set, the output driver on the I/O for CK[0], CK[1], and CK[2] pins, respectively.

Bits 7:5 – CKODT[2:0] CK On-Die Termination
Enables, when set, the on-die termination on the I/O for CK[0], CK[1], and CK[2] pins, respectively.

Bit 4 – ACPDR AC Power Down Receiver
Powers down, when set, the input receiver on the I/O for RAS#, CAS#, WE#, BA[2:0], and A[15:0] pins, as well as the optional DIMM PAR_IN pin and LPDDR TPD pin.

Bit 3 – ACPDD AC Power Down Driver
Powers down, when set, the output driver on the I/O for RAS#, CAS#, WE#, BA[2:0], and A[15:0] pins, as well as the optional DIMM PAR_IN pin.

Bit 2 – ACODT Address/Command On-Die Termination
Enables, when set, the on-die termination on the I/O for RAS#, CAS#, WE#, BA[2:0], and A[15:0] pins, as well as the optional DIMM PAR_IN pin and LPDDR TPD pin.

Bit 1 – ACOE Address/Command Output Enable
Enables, when set, the output driver on the I/O for all address and command pins, as well as the optional DIMM PAR_IN pin and LPDDR TPD pin.

Bit 0 – ACIOM Address/Command I/O Mode
Selects SSTL mode (when set to 0) or CMOS mode (when set to 1) of the I/O for all address and command pins, as well as the optional DIMM PAR_IN pin and LPDDR TPD pin.

18.4.10 DDR3PHY DATX8 Common Configuration Register

Name: DDR3PHY_DXCCR
Offset: 0x28
Reset: 0x00000800
Property: Read/Write

The DATX8 Common Configuration Register is used to control features that affect all the byte lanes. These include on-die termination enables and power-down enables for SSTL I/Os for all SDRAM data, data mask, and data strobe signals.

For D3A I/Os, the IOM register bits connect to the I/O IDDQ pins. Furthermore, the I/O power-down register bits (PDD, PDR, and PD) fields have no relevance for D3A I/Os.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
								AWDT
Access								R/W
Reset								0

Bit	15	14	13	12	11	10	9	8
	RVSEL	DQSNRST	DXSR[1:0]		DQSNRES[3:0]			
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	1	0	0	0

Bit	7	6	5	4	3	2	1	0
	DQSRES[3:0]				DXPDR	DXPDD	DXIOM	DXODT
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit 16 – AWDT Active Window Data Train
Indicates if set that data training (DQS gate training and read valid training) should be performed with active DQS gate window. This is just for debug purposes. The default is to perform training with passive windowing.

Bit 15 – RVSEL ITMD Read Valid Select
Selects the scheme used for ITMD read valid.

Value	Description
0	ITMD read valid signal is generated by delayed DFI read enable signal.
1	ITMD read valid is generated by the ITMD itseld using asynchronous crossing.

Bit 14 – DQSNRST DQS# Reset
Indicates, if set, that the ITMS of DQS# should always be put in reset such that its output enable is always '1' and its data output is always '0'. This is done by driving the oe_set_b and do_rst_b pins of this ITMS to '0' in order to force the unused DQS# PAD to a known state of '0' in applications that don't use DQS# such as in LPDDR mode.

Bits 13:12 – DXSR[1:0] Data Slew Rate (D3F I/O Only)
Selects slew rate of the I/O for DQ, DM, and DQS/DQS# pins of all DATX8 macros.

Bits 11:8 – DQSNRES[3:0] DQS# Resistor
Selects the on-die pull-up/pull-down resistor for DQS# pins. Same encoding as DQSRES.
Note: DQS# resistor must be connected for LPDDR2.

Bits 7:4 – DQSRES[3:0] DQS Resistor
Selects the on-die pull-down/pull-up resistor for DQS pins.

Note: DQS resistor must be connected for LPDDR2.

DQSRES[3] selects pull-down (when set to 0) or pull-up (when set to 1).
DQSRES[2:0] selects the resistor value as follows:

Value	Description
000	Open: On-die resistor disconnected
001	688 ohms
010	611 ohms
011	550 ohms
100	500 ohms
101	458 ohms
110	393 ohms
111	344 ohms

Bit 3 – DXPDR Data Power Down Receiver
Powers down, when set, the input receiver on I/O for
DQ, DM, and DQS/DQS# pins of all DATX8 macros. It also powers down the PDQSR cell of all DAXT8 macros. This bit is ORed with the PDR and DQSRPD configuration bits of the individual DATX8.

Bit 2 – DXPDD Data Power Down Driver
Powers down, when set, the output driver on I/O for DQ, DM, and DQS/DQS# pins of all DATX8 macros. This bit is ORed with the PDD configuration bit of the individual DATX8.

Bit 1 – DXIOM Data I/O Mode
Selects SSTL mode (when set to 0) or CMOS mode (when set to 1) of the I/O for DQ, DM, and DQS/DQS# pins of all DATX8 macros. This bit is ORed with the IOM configuration bit of the individual DATX8.

Bit 0 – DXODT Data On-Die Termination
Enables, when set, the on-die termination on the I/O for DQ, DM, and DQS/DQS# pins of all DATX8 macros. This bit is ORed with the ODT configuration bit of the individual DATX8.

18.4.11 DDR3PHY DDR System General Configuration Register

Name: DDR3PHY_DSGCR
Offset: 0x2C
Reset: 0xFA00001F
Property: Read/Write

The DDR System General Configuration Register is used to configure miscellaneous features of the DDR system including the DFI 2.1 logic in the PUBL.

Bit	31	30	29	28	27	26	25	24
	CKEOE	RSTOE	ODTOE	CKOE	TPDOE	TPDPD	NL2OE	NL2PD
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	1	1	1	1	1	0	1	0

Bit	23	22	21	20	19	18	17	16
	ODTPDD[3:0]				CKEPDD[3:0]			
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
				FXDLAT	NOBUB	DQSGE[2:0]		
Access				R/W	R/W	R/W	R/W	R/W
Reset				0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	DQSGX[2:0]			LPDLLPD	LPIOPD	ZUEN	BDISEN	PUREN
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	1	1	1	1	1

Bit 31 – CKEOE SDRAM CKE Output Enable
Enables, when set, the output driver on the I/O for SDRAM CKE pins.

Bit 30 – RSTOE SDRAM Reset Output Enable
Enables, when set, the output driver on the I/O for SDRAM RST# pin.

Bit 29 – ODTOE SDRAM ODT Output Enable
Enables, when set, the output driver on the I/O for SDRAM ODT pins.

Bit 28 – CKOE SDRAM CK Output Enable
Enables, when set, the output driver on the I/O for SDRAM CK/CK# pins.

Bit 27 – TPDOE SDRAM TPD Output Enable (LPDDR Only)
Enables, when set, the output driver on the I/O for SDRAM TPD pin.

Bit 26 – TPDPD SDRAM TPD Power Down Driver (LPDDR Only)
Powers down, when set, the output driver on the I/O for SDRAM TPD pin. Note that the power down of the receiver on the I/O for SDRAM TPD pin is controlled by ACIOCR[ACPDR] register bit.

Bit 25 – NL2OE Non-LPDDR2/LPDDR3 Output Enable
Enables, when set, the output driver on the I/O for non-LPDDR2/LPDDR3 (ODT, RAS#, CAS#, WE#, and BA) pins. This may be used when a chip that is designed for both LPDDR2/LPDDR3 and other DDR modes is being used in LPDDR2/LPDDR3 mode. For these pins, the I/O output enable signal (OE) is an AND of this bit and the respective output enable bit in ACIOCR or DSGCR registers.

Bit 24 – NL2PD Non-LPDDR2/LPDDR3 Power Down
Powers down, when set, the output driver and the input receiver on the I/O for non-LPDDR2/LPDDR3 (ODT, RAS#, CAS#, WE#, and BA) pins. This may be used when a chip that is designed for both LPDDR2/LPDDR3 and other DDR modes is being used in LPDDR2/LPDDR3 mode. For these pins, the I/O power down signal (PDD or PDR) is an OR of this bit and the respective power-down bit in ACIOCR register.

Bits 23:20 – ODTPDD[3:0] ODT Power Down Driver
Powers down, when set, the output driver on the I/O for ODT[3:0] pins. ODTPDD[0] controls the power down for ODT[0], ODTPDD[1] controls the power down for ODT[1], and so on.

Bits 19:16 – CKEPDD[3:0] CKE Power Down Driver
Powers down, when set, the output driver on the I/O for CKE[3:0] pins. CKEPDD[0] controls the power down for CKE[0], CKEPDD[1] controls the power down for CKE[1], and so on.

Bit 12 – FXDLAT Fixed Latency
Specifies whether all reads should be returned to the controller with a fixed read latency. Enabling fixed read latency increases the read latency.
If the design is compiled for HDR mode, then either NOBUB or FXDLAT must be set to 1.

Value	Description
0	Disable fixed read latency
1	Enable fixed read latency

Bit 11 – NOBUB No Bubbles
Specifies whether reads should be returned to the controller with no bubbles. Enabling no-bubble reads increases the read latency.
If the design is compiled for HDR mode, then either NOBUB or FXDLAT must be set to 1.

Value	Description
0	Bubbles are allowed during reads
1	Bubbles are not allowed during reads

Bits 10:8 – DQSGE[2:0] DQS Gate Early
Specifies the number of clock cycles for which the DQS gating must be enabled earlier than its normal position. Only applicable when using PDQSR I/O cell, passive DQS gating and no drift compensation. This field is recommended to be set to zero for all DDR types other than LPDDR2/LPDDR3. For LPDDR2/LPDDR3 it should be set to (tDQSCKmax - tDQSCKmin) divided by clock period and rounded up. tDQSCKmax and tDQSCKmin can be found in the LPDDR2 vendor datasheet.

Bits 7:5 – DQSGX[2:0] DQS Gate Extension
Specifies the number of clock cycles for which the DQS gating must be extended beyond the normal burst length width. Only applicable when using PDQSR I/O cell, passive DQS gating and no drift compensation. This field is recommended to be set to zero for all DDR types other than LPDDR2/LPDDR3. For LPDDR2/LPDDR3 it should be set to (tDQSCKmax. - tDQSCKmin), divided by clock period and rounded up. tDQSCKmax and tDQSCKmin can be found in the LPDDR2 vendor datasheet.

Bit 4 – LPDLLPD Low Power DLL Power Down
Specifies if set that the PHY should respond to the DFI low power opportunity request and power down the DLL of the PHY if the wakeup time request satisfies the DLL lock time.

Bit 3 – LPIOPD Low Power I/O Power Down
Specifies if set that the PHY should respond to the DFI low power opportunity request and power down the I/Os of the PHY.

Bit 2 – ZUEN Impedance Update Enable
Specifies if set that the PHY should perform impedance calibration (update) whenever there is a controller initiated DFI update request. Otherwise the PHY will ignore an update request from the controller.

Bit 1 – BDISEN Byte Disable Enable
Specifies if set that the PHY should respond to DFI byte disable request. Otherwise the byte disable from the DFI is ignored in which case bytes can only be disabled using the DXnGCR register.

Bit 0 – PUREN PHY Update Request Enable
Specifies if set, that the PHY should issue PHYinitiated DFI update request when there is DQS drift of more than ¾ of a clock cycle within one continuous (back-to-back) read burst. By default the PHY issues PHYinitiated update requests and the controller should respond otherwise the PHY may return erroneous values. The option to disable it is provided only for silicon evaluation and testing.

18.4.12 DDR3PHY DRAM Configuration Register

Name: DDR3PHY_DCR
Offset: 0x30
Reset: 0x0000000B
Property: Read/Write

This register is used to configure the DRAM system.

Bit	31	30	29	28	27	26	25	24
	TPD	RDIMM	UDIMM	DDR2T	NOSRA			
Access	R/W	R/W	R/W	R/W	R/W			
Reset	0	0	0	0	0			

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
							DDRTYPE[1:0]	
Access							R/W	R/W
Reset							0	0

Bit	7	6	5	4	3	2	1	0
	MPRDQ	PDQ[2:0]			DDR8BNK	DDRMD[2:0]		
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	1	0	1	1

Bit 31 – TPD Test Power Down (LPDDR Only)
If set will place the DRAM in Deep Power Down mode.

Bit 30 – RDIMM Registered DIMM
Indicates if set that a registered DIMM is used. In this case, the PUBL increases the SDRAM write and read latencies (WL/RL) by 1. This only applies to PUBL internal SDRAM transactions. Transactions generated by the controller must make its own adjustments to WL/RL when using a registered DIMM.

Bit 29 – UDIMM Un-buffered DIMM Address Mirroring
Indicates if set that there is address mirroring on the second rank of an un-buffered DIMM (the rank connected to CS#[1]). In this case, the PUBL re-scrambles the bank and address when sending mode register commands to the second rank. This only applies to PUBL internal SDRAM transactions. Transactions generated by the controller must make its own adjustments when using an un-buffered DIMM. DCR[NOSRA] must be set if address mirroring is enabled.

Bit 28 – DDR2T DDR 2T Timing
Indicates if set that 2T timing should be used by PUBL internally generated SDRAM transactions.

Bit 27 – NOSRA No Simultaneous Rank Access
Specifies if set that simultaneous rank access on the same clock cycle is not allowed. This means that multiple chip select signals should not be asserted at the same time. This may be required on some DIMM systems.

Bits 9:8 – DDRTYPE[1:0] DDR Type
Selects the DDR type for the specified LPDDR mode.
Valid values for LPDDR2 are:

Value	Description
00	LPDDR2-S4
01	LPDDR2-S2

Value	Description
10	Reserved
11	Reserved

Bit 7 – MPRDQ Multi-Purpose Register (MPR) DQ (DDR3 Only)
Specifies the value that is driven on non-primary DQ pins during MPR reads.

Value	Description
0	Primary DQ drives out the data from MPR (0-1-0-1), non-primary DQs drive ‘0’.
1	Primary DQ and non-primary DQs all drive the same data from MPR (0-1-0-1).

Bits 6:4 – PDQ[2:0] Primary DQ (DDR3 Only)
Specifies the DQ pin in a byte that is designated as a primary pin for Multi-Purpose Register (MPR) reads. Valid values are 0 to 7 for DQ[0] to DQ[7], respectively.

Bit 3 – DDR8BNK DDR 8-Bank
Indicates if set that the SDRAM used has 8 banks. tRPA = tRP+1 and tFAW are used for 8-bank DRAMs, other tRPA = tRP and no tFAW is used. Note that a setting of 1 for DRAMs that have fewer than 8 banks still results in correct functionality but less tighter DRAM command spacing for the parameters described here.

Bits 2:0 – DDRMD[2:0] DDR Mode
SDRAM DDR mode.

Value	Description
001	DDR
010	DDR 2
011	DDR 3
100	LPDDR2 (Mobile DDR2)
101	LPDDR3 (Mobile DDR3)
110 - 111	Reserved

18.4.13 DDR3PHY DRAM Timing Parameters Register 0

Name: DDR3PHY_DTPR0
Offset: 0x34
Reset: 0x3092666E
Property: Read/Write

Various timings for the SDRAM are programmable for compatibility with different speed grades or different vendors. The tables describe the parameters that can be programmed through the SDRAM Timing Parameters Registers. These timing parameters are in clock cycles and are derived from corresponding parameters in the SDRAM datasheet divided by the clock cycle time. Non-integer values should be rounded up to the next integer. All the default values s are in decimal format and are for a 400MHz 1Gb x 16 DDR2800E SDRAM. Refer to the SDRAM datasheet for detailed description about these timing parameters.

	tWTR[2:0]			tRTP[2:0]			tMRD[1:0]	
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	1	1	0	1	1	1	0

Bit 31 – tCCD Read to read and write to write command delay

Value	Description
0	BL/2 for DDR2 and 4 for DDR3
1	BL/2 + 1 for DDR2 and 5 for DDR3

Bits 30:25 – tRC[5:0] Activate to activate command delay (same bank)
Activate to activate command delay (same bank). Valid values are 2 to 42.

Bits 24:21 – tRRD[3:0] Activate to activate command delay (different banks)
Activate to activate command delay (different banks). Valid values are 1 to 8.

Bits 20:16 – tRAS[4:0] Activate to precharge command delay.
Valid values are 2 to 31.

Bits 15:12 – tRCD[3:0] Activate to read or write delay.
Minimum time from when an activate command is issued to when a read or write to the activated row can be issued. Valid values are 2 to 11.

Bits 11:8 – tRP[3:0] Precharge command period
The minimum time between a precharge command and any other command. Note that the Controller automatically derives tRPA for 8bank DDR2 devices by adding 1 to tRP. Valid values are 2 to 11.

Bits 7:5 – tWTR[2:0] Internal write to read command delay.
Internal write to read command delay. Valid values are 1 to 6.

Bits 4:2 – tRTP[2:0] Internal read to precharge command delay.
Internal read to precharge command delay. Valid values are 2 to 6. Note that even though RTP does not apply to JEDEC DDR devices, this parameter must still be set to a minimum value of 2 for DDR because the Controller always uses the DDR2 equation, AL + BL/2 + max(RTP,2) – 2, to compute the read to precharge timing (which is BL/2 for JEDEC DDR).

Bits 1:0 – tMRD[1:0] Load mode cycle time
The minimum time between a load mode register command and any other command. For DDR3 this is the minimum time between two load mode register commands. Valid values for DDR2 are 2 to 3. For DDR3, the value used for tMRD is 4 plus the value programmed in these bits, i.e. tMRD value for DDR3 ranges from 4 to 7. For LPDDR3, the value used for tMRD is 8 plus the value programmed in these bits.

18.4.14 DDR3PHY DRAM Timing Parameter Register 1

Name: DDR3PHY_DTPR1
Offset: 0x38
Reset: 0x09830090
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
			tDQSCKmax[2:0]			tDQSCKmin[2:0]		
Access			R/W	R/W	R/W	R/W	R/W	R/W

					tRTODT	tMOD[1:0]		tFAW[5]
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bit	7	6	5	4	3	2	1	0
	tFAW[4:0]					tRTW	tAOND/ tAOFD[1:0]	
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	1	0	0	1	0	0	0	0

Bits 29:27 – tDQSCKmax[2:0] Maximum DQS output access time from CK/CK# (LPDDR2 only)
This value is used for implementing read-to-write spacing. Valid values are 1 to 7.

Bits 26:24 – tDQSCKmin[2:0] DQS output access time from CK/CK# (LPDDR2/3 only)
This value is used for computing the read latency. Valid values are 0 to 7. This value is derived from the corresponding parameter in the SDRAM datasheet divided by the clock cycle time without rounding up. The fractional remainder is automatically adjusted for by data training in quarter clock cycle units. If data training is not performed then this fractional remainder must be converted to quarter clock cycle units and the gating registers (DXnDQSTR) adjusted accordingly.

Bits 23:16 – tRFC[7:0] Refresh-to-Refresh
Indicates the minimum time, in clock cycles, between two refresh commands or between a refresh and an active command. This is derived from the minimum refresh interval from the datasheet, tRFC(min), divided by the clock cycle time. The default number of clock cycles is for the largest JEDEC tRFC(min parameter value supported.

Bit 11 – tRTODT Read to ODT delay (DDR3 only)
Specifies whether ODT can be enabled immediately after the read post-amble or one clock delay has to be added. If tRTODT is set to 1, then the read-to-write latency is increased by 1 if ODT is enabled.

Value	Description
0	ODT may be turned on immediately after read post-amble
1	ODT may not be turned on until one clock after the read post-amble

Bits 10:9 – tMOD[1:0] Load mode update delay (DDR3 only)
The minimum time between a load mode register command and a non-load mode register command.

Value	Description
00	12
01	13
10	14
11	15

Bits 8:3 – tFAW[5:0] 4-bank activate period
No more than 4-bank activate commands may be issued in a given tFAW period. Only applies to 8-bank devices. Valid values are 2 to 31.

Bit 2 – tRTW Read to Write command delay
This parameter allows the user to increase the delay between issuing Write commands to the SDRAM when preceded by Read commands. This provides an option to increase bus turn-around margin for high frequency systems.

Value	Description
0	Standard bus turn around delay
1	Adds 1 clock to standard bus turn around delay

Bits 1:0 – tAOND/ tAOFD[1:0] ODT turn-on/turn-off delays (DDR2 only)
The delays are in clock cycles.
Most DDR2 devices utilize a fixed value of 2/2.5. For non-standard SDRAMs, the user must ensure that the operational Write Latency is always greater than or equal to the ODT turn-on delay. For example, a DDR2 SDRAM with CAS latency set to 3 and CAS additive latency set to 0 has a Write Latency of 2. Thus 2/2.5 can be used, but not 3/3.5 or higher.

Value	Description
00	2/2.5
01	3/3.5
10	4/4.5
11	5/5.5

18.4.15 DDR3PHY DRAM Timing Parameter Register 2

Name: DDR3PHY_DTPR2
Offset: 0x3C
Reset: 0x1001A0C8
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
				tDLLK[9:5]				
Access				R/W	R/W	R/W	R/W	R/W

Reset	1	1	0	0	1	0	0	0

Bits 28:19 – tDLLK[9:0] DLL locking time
Valid values are 2 to 1023.

Bits 18:15 – tCKE[3:0] CKE minimum pulse width
Also specifies the minimum time that the SDRAM must remain in Power-down or Self-refresh mode. For DDR3 this parameter must be set to the value of tCKESR which is usually bigger than the value of tCKE. Valid values are 2 to 15.

Bits 14:10 – tXP[4:0] Power down exit delay
The minimum time between a power down exit command and any other command. This parameter must be set to the maximum of the various minimum power down exit delay parameters specified in the SDRAM datasheet, i.e. max(tXP, tXARD, tXARDS) for DDR2 and max(tXP, tXPDLL) for DDR3. Valid values are 2 to 31.

Bits 9:0 – tXS[9:0] Self refresh exit delay
The minimum time between a self refresh exit command and any other command. This parameter must be set to the maximum of the various minimum self refresh exit delay parameters specified in the SDRAM datasheet, i.e. max(tXSNR, tXSRD) for DDR2 and max(tXS, tXSDLL) for DDR3. Valid values are 2 to 1023.

18.4.16 DDR3PHY Mode Register 0 (MR0) (DDR3 Mode)

Name: DDR3PHY_MR0_DDR3
Offset: 0x40
Reset: 0x00000294
Property: Read/Write

SDRAM definitions controlled by the Mode Register 0 (MR0) include, among other things, burst length, burst type, CAS latency, operating (normal or test) mode, DLL reset, write recovery, and power-down modes. The PUBL Mode Register 0 (MR0) maps to DDR3 Mode Register 0 (MR0), DDR2 Mode Register (MR) and DDR Mode Register (MR).

Bit 12 – PD Power-Down Control
Controls the exit time for power-down modes. Refer to the SDRAM datasheet for details on power-down modes.

Value	Description
0	Slow exit (DLL off)
1	Fast exit (DLL on)

Bits 11:9 – WR[2:0] Write Recovery
This is the value of the write recovery in clock cycles. It is calculated by dividing the datasheet write recovery time, tWR (ns) by the datasheet clock cycle time, tCK (ns) and rounding up a non-integer value to the next integer.
Note: tWR (ns) is the time from the first SDRAM positive clock edge after the last data-in pair of a write command, to when a precharge of the same bank can be issued.
Valid values are as follows. All other settings are reserved and should not be used.

Value	Description
001	5
010	6
011	7
100	8
101	10
110	12

Bit 8 – DR DLL Reset
Writing a ‘1’ to this bit will reset the SDRAM DLL. This bit is selfclearing, i.e. it returns back to ‘0’ after the DLL reset has been issued.

Bit 7 – TM Operating Mode
Selects either normal operating mode (0) or test mode (1). Test mode is reserved for the manufacturer and should not be used.

Bit 6 – CL3 CAS Latency
The delay, in clock cycles, between when the SDRAM registers a read command to when data is available.
CL3, CL2, CL1, CL0= MR0 [6:4,2]
Valid values are as follows. All other settings are reserved and should not be used.

Value	Description
0010	5
0100	6
0110	7
1000	8
1010	9
1100	10
1110	11

Bit 5 – CL2 CAS Latency
See CL3.
CL = MR0 [6:4,2]

Bit 4 – CL1 CAS Latency
See CL3.
CL = MR0 [6:4,2]

Bit 3 – BT Burst Type
Indicates whether a burst is sequential or interleaved.

Value	Description
0	Sequential burst
1	Interleaved burst

Bit 2 – CL0 CAS Latency
See CL3.
CL = MR0 [6:4,2]

Bits 1:0 – BL[1:0] Burst Length
Determines the maximum number of column locations that can be accessed during a given read or write command.
Valid values are as follows.

Value	Description
00	8 (fixed)
01	4 or 8 (on the fly)
10	4 (fixed)
11	Reserved

18.4.17 DDR3PHY Mode Register 0 (MR0) (DDR2 Mode)

Name: DDR3PHY_MR0_DDR2
Offset: 0x40
Reset: 0x00000A52
Property: Read/Write

SDRAM definitions controlled by the Mode Register 0 (MR0) include, among other things, burst length, burst type, CAS latency, operating (normal or test) mode, DLL reset, write recovery, and power-down modes. The PUBL Mode Register 0 (MR0) maps to DDR3 Mode Register 0 (MR0), DDR2 Mode Register (MR) and DDR Mode Register (MR).

Bit 12 – PD Power-Down Control
Controls the exit time for power-down modes. Refer to the SDRAM datasheet for details on power-down modes.

Value	Description
0	Fast exit
1	Slow exit

Bits 11:9 – WR[2:0] Write Recovery
This is the value of the write recovery in clock cycles. It is calculated by dividing the datasheet write recovery time, tWR (ns) by the datasheet clock cycle time, tCK (ns) and rounding up a non-integer value to the next integer.
Note: tWR (ns) is the time from the first SDRAM positive clock edge after the last data-in pair of a write command, to when a precharge of the same bank can be issued.
Valid values are as follows. All other settings are reserved and should not be used.

Value	Description
001	2
010	3
011	4
100	5
101	6

Bit 8 – DR DLL Reset
Writing a ‘1’ to this bit will reset the SDRAM DLL. This bit is selfclearing, i.e. it returns back to ‘0’ after the DLL reset has been issued.

Bit 7 – TM Operating Mode
Selects either normal operating mode (0) or test mode (1). Test mode is reserved for the manufacturer and should not be used.

Bits 6:4 – CL[2:0] CAS Latency
The delay, in clock cycles, between when the SDRAM registers a read command to when data is available. Valid values are as follows. All other settings are reserved and should not be used.

Value	Description
010	2
011	3
100	4
101	5
110	6

Bit 3 – BT Burst Type
Indicates whether a burst is sequential or interleaved.

Value	Description
0	Sequential burst
1	Interleaved burst

Bits 2:0 – BL[2:0] Burst Length
Determines the maximum number of column locations that can be accessed during a given read or write command. Valid values are as follows. All other settings are reserved and should not be used.

Value	Description
010	4
011	8

18.4.18 DDR3PHY Mode Register 0 (MR0) (DDR Mode)

Name: DDR3PHY_MR0_DDR
Offset: 0x40
Reset: 0x00000A52
Property: Read/Write

SDRAM definitions controlled by the Mode Register 0 (MR0) include, among other things, Burst Length, Burst Type, CAS Latency, Operating (Normal or Test) mode, DLL Reset, Write Recovery, and Power-down modes. The PUBL Mode Register 0 (MR0) maps to DDR3 Mode Register 0 (MR0), DDR2 Mode Register (MR) and DDR Mode Register (MR).

001	2
010	4
011	8

18.4.19 DDR3PHY Mode Register 1 (MR1) (DDR3 Mode)

Name: DDR3PHY_MR1_DDR3
Offset: 0x44
Reset: 0x00000000
Property: Read/Write

SDRAM definitions controlled by the Mode register 1 (MR1) include, among other things, DLL enable/disable, drive strength, on-die termination (ODT) resistance, CAS additive latency, off-chip driver (OCD) impedance calibration, DQS_b and RDQS/RDQS_b enable/disable, and output enable. The PUBL Mode Register 1 (MR1) maps to DDR3 Mode Register 1 (MR1), DDR2 Extended Mode Register (EMR), DDR Extended Mode Register (EMR), LPDDR2 Mode Register 1 (MR1), and LPDDR3 Mode Register 1 (MR1).

Reset	0	0	0	0	0	0	0	0

Bit 12 – QOFF Output Enable/Disable
When '0', all outputs function normally; when '1', all SDRAM outputs are disabled removing output buffer current. This feature is intended to be used for IDD characterization of read current and should not be used in normal operation.

Bit 11 – TDQS Termination Data Strobe
When enabled ('1') TDQS provides additional termination resistance outputs that may be useful in some system configurations. Refer to the SDRAM datasheet for details.

Bit 9 – RTT2 On Die Termination
Selects the effective resistance for SDRAM on die termination. RTT2-RTT1-RTT0: Valid values are as follows. All other settings are reserved and should not be used.

Value	Description
000	ODT disabled
001	RZQ/4
010	RZQ/2
011	RZQ/6
100	RZQ/12
101	RZQ/8

Bit 7 – LEVEL Write Leveling Enable
Enables write-leveling when set.

Bit 6 – RTT1 On Die Termination
Selects the effective resistance for SDRAM on die termination. See RTT2.

Bit 5 – DIC1 Output Driver Impedance Control
Controls the output drive strength. DIC1-DIC0: Valid values are as follows.

Value	Description
00	RZQ/6
01	RZQ/7
10	Reserved
11	Reserved

Bits 4:3 – AL[1:0] Posted CAS Additive Latency
Setting additive latency that allows read and write commands to be issued to the SDRAM earlier than normal (refer to the SDRAM datasheet for details).

Value	Description
00	0 (AL disabled)
01	CL - 1
10	CL - 2
11	Reserved

Bit 2 – RTT0 On Die Termination
Selects the effective resistance for SDRAM on die termination. See RTT2.

Bit 1 – DIC0 Output Driver Impedance Control
See DIC1.

Bit 0 – DE DLL Enable/Disable
DLL must be enabled for normal operation.

Value	Description
0	Enable the DLL
1	Disable the DLL

18.4.20 DDR3PHY Mode Register 1 (MR1) (DDR2 Mode)

Name: DDR3PHY_MR1_DDR2
Offset: 0x44
Reset: 0x00000000
Property: Read/Write

SDRAM definitions controlled by the Mode register 1 (MR1) include, among other things, DLL enable/disable, drive strength, on-die termination (ODT) resistance, CAS additive latency, off-chip driver (OCD) impedance calibration, DQS_b and RDQS/RDQS_b enable/disable, and output enable. The PUBL Mode Register 1 (MR1) maps to DDR3 Mode Register 1 (MR1), DDR2 Extended Mode Register (EMR), DDR Extended Mode Register (EMR), LPDDR2 Mode Register 1 (MR1), and LPDDR3 Mode Register 1 (MR1).

	OCD[0]	RTT1	AL[2:0]			RTT0	DIC	DE
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit 12 – QOFF Output Enable/Disable
When ‘0’, all outputs function normal, when ‘1’ all SDRAM outputs are disabled removing output buffer current. This feature is intended to be used for IDD characterization of read current and should not be used in normal operation.

Bit 11 – RDQS RDQS Enable/Disable
When enabled (‘1’), RDQS is identical in function and timing to data strobe DQS during a read, and ignored during a write. A ‘0’ disables the SDRAM from driving RDQS. The Controller does not allow the user to change this bit.

Bit 10 – DQS DQS_b Enable/Disable
When ‘0’, DQS_b is the complement of the differential data strobe pair DQS/DQS_b. When ‘1’, DQS is used in a single-ended mode and the DQS_b pin is disabled. Also used to similarly enable/disable RDQS_b if RDQS is enabled. The Controller does not allow the user to change this bit.

Bits 9:7 – OCD[2:0] Off-Chip Driver (OCD) Impedance Calibration
Used to calibrate and match pull-up to pull-down impedance to 18 Ω nominal (refer to the SDRAM datasheet for details). Note that OCD is not supported by all vendors. Refer to the SDRAM datasheet for details on the recommended OCD settings. Valid values are as follows. All other settings are reserved and should not be used.

Value	Description
`000`	OCD calibration mode exit
`001`	Drive (1) pull-up
`010`	Drive (0) pull-down
`100`	OCD enter adjust mode
`111`	OCD calibration default

Bit 6 – RTT1 On Die Termination
Selects the effective resistance for SDRAM on die termination.
RTT1-RTT0: Valid values are as follows.

Value	Description
00	ODT disabled
01	75 Ω
10	150 Ω
11	50 Ω (some vendors)

Bits 5:3 – AL[2:0] Posted CAS Additive Latency
Setting additive latency that allows read and write commands to be issued to the SDRAM earlier than normal (refer to the SDRAM datasheet for details). Valid values are as follows. All other settings are reserved and should not be used. The maximum allowed value of AL is tRCD-1.

Value	Description
000	0
001	1
010	2
011	3
100	4
101	5

Bit 2 – RTT0 On Die Termination
Selects the effective resistance for SDRAM on die termination. See RTT1.

Bit 1 – DIC Output Driver Impedance Control
Controls the output drive strength.

Value	Description
0	Full strength
1	Reduced strength

Bit 0 – DE DLL Enable/Disable
DLL must be enabled for normal operation.

Value	Description
0	Enable the DLL
1	Disable the DLL

18.4.21 DDR3PHY Mode Register 1 (MR1) (DDR Mode)

Name: DDR3PHY_MR1_DDR
Offset: 0x44
Reset: 0x00000000
Property: Read/Write

SDRAM definitions controlled by the Mode register 1 (MR1) include, among other things, DLL enable/disable, drive strength, on-die termination (ODT) resistance, CAS additive latency, off-chip driver (OCD) impedance calibration, DQS_b and RDQS/RDQS_b enable/disable, and output enable. The PUBL Mode Register 1 (MR1) maps to DDR3 Mode Register 1 (MR1), DDR2 Extended Mode Register (EMR), DDR Extended Mode Register (EMR), LPDDR2 Mode Register 1 (MR1), and LPDDR3 Mode Register 1 (MR1).

Valid values are as follows. All other settings are reserved and should not be used.

Value	Description
001	3
010	4
011	5
100	6
101	7
110	8

Bit 4 – WC Wrap Control

Value	Description
0	Wrap
1	No wrap

Bit 3 – BT Burst Type
Indicates whether a burst is sequential or interleaved.

Value	Description
0	Sequential burst
1	Interleaved burst

Bits 2:0 – BL[2:0] Burst Length
Determines the maximum number of column locations that can be accessed during a given read or write command. Valid values are as follows. All other settings are reserved and should not be used.

Value	Description
010	4
011	8
100	16

18.4.23 DDR3PHY Mode Register 1 (MR1) (LPDDR3 Mode)

Name: DDR3PHY_MR1_LPDDR3
Offset: 0x44
Reset: 0x00000002
Property: Read/Write

SDRAM definitions controlled by the Mode register 1 (MR1) include, among other things, DLL enable/disable, drive strength, on-die termination (ODT) resistance, CAS additive latency, off-chip driver (OCD) impedance calibration, DQS_b and RDQS/RDQS_b enable/disable, and output enable. The PUBL Mode Register 1 (MR1) maps to DDR3 Mode Register 1 (MR1), DDR2 Extended Mode Register (EMR), DDR Extended Mode Register (EMR), LPDDR2 Mode Register 1 (MR1), and LPDDR3 Mode Register 1 (MR1).

Bit	31	30	29	28	27	26	25	24

Bit	7	6	5	4	3	2	1	0
		nWR[2:0]					BL[2:0]	
Access	R/W	R/W	R/W			R/W	R/W	R/W
Reset	0	0	0			0	1	0

Bits 7:5 – nWR[2:0] Write Recovery
Valid values are as follows. All other settings are reserved and should not be used.

Value	Description
	If nWRE (MR2 [4]) = 0:
001B	nWR=3
100B	nWR=6
110B	nWR=8
111B	nWR=9
	If nWRE (MR2[4]) = 1:
000B	nWR=10
001B	nWR=11
010B	nWR=12

Bits 2:0 – BL[2:0] Burst Length
Determines the maximum number of column locations that can be accessed during a given read or write command. Valid values are: 011 = 8 All other settings are reserved and should not be used.

18.4.24 DDR3PHY Mode Register 2 (MR2/EMR2) (DDR3 Mode)

Name: DDR3PHY_MR2_DDR3
Offset: 0x48
Reset: 0x00000000
Property: Read/Write

Mode Register 2 controls among other things refresh related features of SDRAMs. The PUBL Mode Register 2 (MR2) maps to DDR3 Mode Register 2 (MR2), DDR2 Extended Mode Register 2 (EMR2), LPDDR2 Mode Register 2 (MR2) and LPDDR3 Mode Register 2 (MR2).

Note that LPDDR EMR register is mapped to the PUBL MR2 register because the SDRAM address for the this register is BA[1:0] = 2'b10.

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 15:11 – RSVD[4:0] Reserved
These are JEDEC reserved bits and are recommended by JEDEC to be programmed to ‘0’.

Bits 10:9 – RTTWR[1:0] Dynamic ODT
Selects RTT for dynamic ODT.

Value	Description
`00`	Dynamic ODT off
`01`	RZQ/4
`10`	RZQ/2
`11`	Reserved

Bit 7 – SRT Self-Refresh Temperature Range
Selects either normal or extended operating temperature range during self-refresh.

Value	Description
`0`	Normal self-refresh temperature range
`1`	Extended self-refresh temperature range

Bit 6 – ASR Auto Self-Refresh
When enabled (‘1’), SDRAM automatically provides self-refresh power management functions for all supported operating temperature values.
Otherwise the SRT bit must be programmed to indicate the temperature range.

Bits 5:3 – CWL[2:0] CAS Write Latency
The delay, in clock cycles, between when the SDRAM registers a write command to when write data is available. Valid values are as follows. All other settings are reserved and should not be used.

Value	Description
000	5 (tCK = 2.5 ns)
001	6 (2.5 ns > tCK = 1.875 ns)
010	7 (1.875 ns > tCK = 1.5 ns)
011	8 (1.5 ns > tCK = 1.25 ns)

Bits 2:0 – PASR[2:0] Partial Array Self Refresh
Specifies that data located in areas of the array beyond the specified location will be lost if self refresh is entered.

Value	Description
	Valid settings for 4 banks:
000	Full Array
001	Half Array (BA[1:0] = 00 & 01)
010	Quarter Array (BA[1:0] = 00)
011	Not defined
100	3/4 Array (BA[1:0] = 01, 10, & 11)
101	Half Array (BA[1:0] = 10 & 11)
110	Quarter Array (BA[1:0] = 11)
111	Not defined
	Valid settings for 8 banks:
000	Full Array
001	Half Array (BA[2:0] = 000, 001, 010 & 011)
010	Quarter Array (BA[2:0] = 000, 001)
011	1/8 Array (BA[2:0] = 000)
100	3/4 Array (BA[2:0] = 010, 011, 100, 101, 110 & 111)
101	Half Array (BA[2:0] = 100, 101, 110 & 111)
110	Quarter Array (BA[2:0] = 110 & 111)
111	1/8 Array (BA[2:0] 111)

18.4.25 DDR3PHY Mode Register 2 (MR2/EMR2) (DDR2 Mode)

Name: DDR3PHY_MR2_DDR2
Offset: 0x48
Reset: 0x00000000
Property: Read/Write

Mode Register 2 controls among other things refresh related features of SDRAMs. The PUBL Mode Register 2 (MR2) maps to DDR3 Mode Register 2 (MR2), DDR2 Extended Mode Register 2 (EMR2), LPDDR2 Mode Register 2 (MR2) and LPDDR3 Mode Register 2 (MR2).

Bits 15:11 – RSVD[4:0] Reserved
These are JEDEC reserved bits and are recommended by JEDEC to be programmed to ‘0’

Bit 7 – SRF Self Refresh Rate
Enables, if set, high temperature self refresh rate.

Bit 3 – DCC Duty Cycle Corrector
Enables, if set, duty cycle correction within SDRAM.

Bits 2:0 – PASR[2:0] Partial Array Self Refresh
Specifies that data located in areas of the array beyond the specified location will be lost if self refresh is entered.

Value	Description
	Valid settings for 4 banks:
000	Full Array
001	Half Array (BA[1:0] = 00 & 01)
010	Quarter Array (BA[1:0] = 00)
011	Not defined
100	3/4 Array (BA[1:0] = 01, 10, & 11)
101	Half Array (BA[1:0] = 10 & 11)
110	Quarter Array (BA[1:0] = 11)
111	Not defined
	Valid settings for 8 banks:
000	Full Array
001	Half Array (BA[2:0] = 000, 001, 010 & 011)
010	Quarter Array (BA[2:0] = 000, 001)
011	1/8 Array (BA[2:0] = 000)

Value	Description
100	3/4 Array (BA[2:0] = 010, 011, 100, 101, 110 & 111)
101	Half Array (BA[2:0] = 100, 101, 110 & 111)
110	Quarter Array (BA[2:0] = 110 & 111)
111	1/8 Array (BA[2:0] 111)

18.4.26 DDR3PHY Mode Register 2 (MR2/EMR2) (LPDDR2 Mode)

Name: DDR3PHY_MR2_LPDDR2
Offset: 0x48
Reset: 0x00000000
Property: Read/Write

Mode Register 2 controls among other things refresh related features of SDRAMs. The PUBL Mode Register 2 (MR2) maps to DDR3 Mode Register 2 (MR2), DDR2 Extended Mode Register 2 (EMR2), LPDDR2 Mode Register 2 (MR2) and LPDDR3 Mode Register 2 (MR2).

Bits 15:3 – RSVD[12:0] Reserved
These are JEDEC reserved bits and are recommended by JEDEC to be programmed to ‘0’

Bit 2 – MPR Multi-Purpose Register Enable
Enables, if set, that read data should come from the Multi-Purpose Register. Otherwise read data come from the DRAM array.

Bits 1:0 – MPRLOC[1:0] Multi-Purpose Register (MPR) Location
Selects MPR data location. Valid value is:
00 = Predefined pattern for system calibration
All other settings are reserved and should not be used.

18.4.29 DDR3PHY Mode Register 3 (MR3) (DDR2 Mode)

Name: DDR3PHY_MR3_EMR3_DDR2
Offset: 0x4C
Reset: 0x00000000
Property: Read/Write

Mode Register 3 controls, among other things, the multi-purpose register. The PUBL Mode Register 3 (MR3) maps to DDR3 Mode Register 3 (MR3), DDR2 Extended Mode Register 3 (EMR3), LPDDR2 Mode Register 3 (MR3), and LPDDR3 Mode Register 3 (MR3).

Reset	0	0	0	0	0	0	0	0

Bits 7:4 – RSVD[3:0] Reserved
These are JEDEC reserved bits and are recommended by JEDEC to be programmed to ‘0’.

Bits 3:2 – PDCTL[1:0] Power Down control

Value	Description
0	ODT disabled by DRAM during power
1	ODT enabled by DRAM during power down

Bits 1:0 – DQODT[1:0] On Die Termination

Value	Description
00	Disable (default)
01	Rzq/4 (optional for LPDDR3- 1066 devices)
10	Rzq/2
11	Rzq/1

18.4.32 DDR3PHY ODT Configuration Register

Name: DDR3PHY_ODTCR
Offset: 0x50
Reset: 0x84210000
Property: Read/Write

This register configures how ODT should be controlled on the different ranks when writing or reading a particular rank. This provides full flexibility on how the overall termination of the SDRAM system is set depending on how many ranks are used and whether the DIMM slots are occupied or not.

Bit	31	30	29	28	27	26	25	24

	RDODT1[3:0]				RDODT0[3:0]			
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 31:28 – WRODT3[3:0] WRODT3

Bits 27:24 – WRODT2[3:0] WRODT2

Bits 23:20 – WRODT1[3:0] WRODT1

Bits 19:16 – WRODT0[3:0] Write ODT
Specifies whether ODT should be enabled (‘1’) or disabled (‘0’) on each of the up to four ranks when a write command is sent to rank n. WRODT0, WRODT1, WRODT2, and WRODT3 specify ODT settings when a write is to rank 0, rank 1, rank 2, and rank 3, respectively. The four bits of each field each represent a rank, the LSB being rank 0 and the MSB being rank 3. Default is to enable ODT only on rank being written to.

Bits 15:12 – RDODT3[3:0] RDODT3

Bits 11:8 – RDODT2[3:0] RDODT2

Bits 7:4 – RDODT1[3:0] RDODT1

Bits 3:0 – RDODT0[3:0] Read ODT
Specifies whether ODT should be enabled (‘1’) or disabled (‘0’) on each of the up to four ranks when a read command is sent to rank n. RDODT0, RDODT1, RDODT2, and RDODT3 specify ODT settings when a read is to rank 0, rank 1, rank 2, and rank 3, respectively. The four bits of each field each represent a rank, the LSB being rank 0 and the MSB being rank 3. Default is to disable ODT during reads.
Note: The RODT bits are applicable to DDR2 only. Since the PUBL does not support DIMM configuration while in DDR3 mode, the Rank ODT signal is not asserted for idle ranks in a multi-rank configuration.

18.4.33 DDR3PHY Data Training Address Register

Name: DDR3PHY_DTAR
Offset: 0x54
Reset: 0x00000000
Property: Read/Write

This register optionally sets the address used during data training.

The data training address is based on a decoded bank/row/column address.

The user should ensure the column address starts at the beginning of a burst-length-16 boundary (A[3:0] = DTCOL[3:0] = 0000).

Bit	31	30	29	28	27	26	25	24

Reset	0	0	0	0	0	0	0	0

Bit 31 – DTMPR Data Training Using MPR (DDR3 Only)
Specifies, if set, that data-training should use the SDRAM Multi-Purpose Register (MPR) register. Otherwise data-training is performed by first writing to some locations in the SDRAM and then reading them back.

Bits 30:28 – DTBANK[2:0] Data Training Bank Address
Selects the SDRAM bank address to be used during data training.

Bits 27:12 – DTROW[15:0] Data Training Row Address
Selects the SDRAM row address to be used during data training.

Bits 11:0 – DTCOL[11:0] Data Training Column Address
Selects the SDRAM column address to be used during data training. The lower four bits of this address must always be “0000”.

18.4.34 DDR3PHY Data Training Data Register 0

Name: DDR3PHY_DTDR0
Offset: 0x58
Reset: 0xDD22EE11
Property: Read/Write

These registers optionally set the 8 data bytes used during data training. Data training uses a total burst length of 8, i.e. one access for burst length of 8, two accesses for burst length of 4 and four accesses for burst length of 2. The data set in DTDR registers is used as the data for each of the 8 data cycles. The data for the first 4 clock cycles (DTBYTE0 to DTBYTE3) come from DTDR0 register, and the data for the last 4 cycles (DTBYT4 to DTBYTE7) come from DTDR1 register.

Bits 31:24 – DTBYTE3[7:0] Data Training Data
The first 4 bytes of data used during data training. This same data byte is used for each byte lane. Default sequence is a walking 1 while toggling data every data cycle.

Bits 23:16 – DTBYTE2[7:0] Data Training Data
The first 4 bytes of data used during data training. This same data byte is used for each byte lane. Default sequence is a walking 1 while toggling data every data cycle.

Bits 15:8 – DTBYTE1[7:0] Data Training Data
The first 4 bytes of data used during data training. This same data byte is used for each byte lane. Default sequence is a walking 1 while toggling data every data cycle.

Bit 0 – DTBYTE0 Data Training Data
The first 4 bytes of data used during data training. This same data byte is used for each byte lane. Default sequence is a walking 1 while toggling data every data cycle.

18.4.35 DDR3PHY Data Training Data Register 1

Name: DDR3PHY_DTDR1
Offset: 0x5C
Reset: 0x7788BB44
Property: Read/Write

These registers optionally set the 8 data bytes used during data training. Data training uses a total burst length of 8, i.e. one access for burst length of 8, two accesses for burst length of 4 and four accesses for burst length of 2. The data set in DTDR registers is used as the data for each of the 8 data cycles. The data for the first 4 clock cycles (DTBYTE0 to DTBYTE3) come from DTDR0 register, and the data for the last 4 cycles (DTBYT4 to DTBYTE7) come from DTDR1 register.

Bits 31:24 – DTBYTE7[7:0] Data Training Data
The second 4 bytes of data used during data training. This same data byte is used for each byte lane. Default sequence is a walking 1 while toggling data every data cycle.

Bits 23:16 – DTBYTE6[7:0] Data Training Data
The second 4 bytes of data used during data training. This same data byte is used for each byte lane. Default sequence is a walking 1 while toggling data every data cycle.

Bits 15:8 – DTBYTE5[7:0] Data Training Data
The second 4 bytes of data used during data training. This same data byte is used for each byte lane. Default sequence is a walking 1 while toggling data every data cycle.

Bits 7:0 – DTBYTE4[7:0] Data Training Data
The second 4 bytes of data used during data training. This same data byte is used for each byte lane. Default sequence is a walking 1 while toggling data every data cycle.

18.4.36 DDR3PHY DCU Address Register

Name: DDR3PHY_DCUAR
Offset: 0xC0
Reset: 0x00000000
Property: Read/Write

DCU Address Register selects the DCU cache and the address of the cache that should be accessed when subsequent configuration writes or reads to the caches is triggered using the DCU Data Register(DCUDR). A write to the DCUAR will automatically transfer the first cache data word into the DCU Data Register (DCUDR) and optionally increment the address if the cache assess is a read.

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit 11 – ATYPE Access Type
Specifies the type of access to be performed using this address.

Value	Description
0	Write access
1	Read access

Bit 10 – INCA Increment Address
Specifies, if set, that the cache address specified in WADDR and SADDR should be automatically incremented after each access of the cache. The increment happens in such a way that all the slices of a selected word are first accessed before going to the next word.

Bits 9:8 – CSEL[1:0] Cache Select
Selects the cache to be accessed.

Value	Description
00	Command cache
01	Expected data cache
10	Read data cache
11	Reserved

Bits 7:4 – CSADDR[3:0] Cache Slice Address
Address of the cache slice to be accessed.

Bits 3:0 – CWADDR[3:0] Cache Word Address
Address of the cache word to be accessed.

18.4.37 DDR3PHY DCU Data Register

Name: DDR3PHY_DCUDR
Offset: 0xC4
Reset: 0x00000000
Property: Read/Write

DCU Data Register is used to hold the data to be written to or read from the cache.

Bit	31	30	29	28	27	26	25	24

Bit 23 – XCEN Expected Compare Enable
Indicates if set that read data coming back from the SDRAM should be should be compared with the expected data.

Bit 22 – RCEN Read Capture Enable
Indicates if set that read data coming back from the SDRAM should be captured into the read data cache.

Bit 21 – SCOF Stop Capture On Full
Specifies if set that the capture of read data should stop when the capture cache is full.

Bit 20 – SONF Stop On Nth Fail
Specifies if set that the execution of commands and the capture of read data should stop when there are N read data failures. The number of failures is specified by NFAIL. Otherwise commands execute until the end of the program or until manually stopped using a STOP command.

Bits 19:12 – NFAIL[7:0] Number of Failures
Specifies the number of failures after which the execution of commands and the capture of read data should stop if SONF bit of this register is set. Execution of commands and the capture of read data will stop after (NFAIL+1) failures if SONF is set.

Bits 11:8 – EADDR[3:0] End Address
Cache word address where the execution of command should end.

Bits 7:4 – SADDR[3:0] Start Address
Cache word address where the execution of commands should begin.

Bits 3:0 – DINST[3:0] DCU Instruction
Selects the DCU command to be executed.

Value	Description
0000	NOP: No operation
0001	Run: Triggers the execution of commands in the command cache
0010	Stop: Stops the execution of commands in the command cache.
0011	Stop Loop: Stops the execution of an infinite loop in the command cache.
0100	Reset: Resets all DCU run time registers
0101 - 1111	Reserved

18.4.39 DDR3PHY DCU Loop Register

Name: DDR3PHY_DCULR
Offset: 0xCC
Reset: 0xF0000000
Property: Read/Write

DCU Loop Register is used to configure the looping when commands are executed from the command cache.

Bit	31	30	29	28	27	26	25	24
	XLEADDR[3:0]							
Access	R/W	R/W	R/W	R/W				
Reset	1	1	1	1

	LEADDR[3:0]				LSADDR[3:0]			
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 31:28 – XLEADDR[3:0] Expected Data Loop End Address
The last expected data cache word address that contains valid expected data. Expected data should looped between 0 and this address.

Bit 17 – IDA Increment DRAM Address
Indicates if set that DRAM addresses should be incremented every time a DRAM read/write command inside the loop is executed.

Bit 16 – LINF Loop Infinite
Indicates if set that the loop should be executed indefinitely until stopped by the STOP command. Otherwise the loop is execute LCNT times.

Bits 15:8 – LCNT[7:0] Loop Count
The number of times that the loop should be executed if LINF is not set.

Bits 7:4 – LEADDR[3:0] Loop End Address
Command cache word address where the loop should end.

Bits 3:0 – LSADDR[3:0] Loop Start Address
Command cache word address where the loop should start.

18.4.40 DDR3PHY DCU General Configuration Register

Name: DDR3PHY_DCUGCR
Offset: 0xD0
Reset: 0x00000000
Property: Read/Write

DCU General Configuration Register is used to specify miscellaneous DCU configurations prior to triggering the execution of commands.

Bit	31	30	29	28	27	26	25	24

Reset	0	0	0	0	0	0	0	0

Bits 15:0 – RCSW[15:0] Read Capture Start Word
The capture and compare of read data should start after Nth word. For example setting this value to 12 will skip the first 12 read data.

18.4.41 DDR3PHY DCU Timing Parameter Register

Name: DDR3PHY_DCUTPR
Offset: 0xD4
Reset: 0x00000000
Property: Read/Write

The DCU Timing Parameter Register is used to program generic timing parameters for the repeat field of the command cache.

Bit	31	30	29	28	27	26	25	24

Bits 23:16 – tDCUT2[7:0] DCU Generic Timing Parameter 2

Bits 15:8 – tDCUT1[7:0] DCU Generic Timing Parameter 1

Bits 7:0 – tDCUT0[7:0] DCU Generic Timing Parameter 0

18.4.42 DDR3PHY DCU Status Register 0

Name: DDR3PHY_DCUSR0
Offset: 0xD8
Reset: 0x00000000
Property: Read/Write

DCU status registers are used to report various status of the DCU, including number of reads returned and number of read failures.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
						CFULL	CFAIL	RDONE
Access						R/W	R/W	R/W
Reset						0	0	0

Bit 2 – CFULL Capture Full
Indicates if set that the capture cache is full.

Bit 1 – CFAIL Capture Fail
Indicates if set that at least one read data word has failed.

Bit 0 – RDONE Run Done
Indicates if set that the DCU has finished executing the commands in the command cache. This bit is also set to indicate that a STOP command has successfully been executed and command execution has stopped.

18.4.43 DDR3PHY DCU Status Register 1

Name: DDR3PHY_DCUSR1
Offset: 0xDC
Reset: 0x00000000
Property: Read/Write

DCU status registers are used to report various status of the DCU, including number of reads returned and number of read failures.

Bit	31	30	29	28	27	26	25	24
	LPCNT[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0
Bit	23	22	21	20	19	18	17	16

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 31:24 – LPCNT[7:0] Loop Count
Indicates the value of the loop count. This is useful when the program has stooped because of failures to assess how many reads were executed before first fail.

Bits 23:16 – FLCND[7:0] Fail Count
Number of read words that have failed.

Bits 15:0 – RDCNT[15:0] Read Count
Number of read words returned from the SDRAM.

18.4.44 DDR3PHY BIST Run Register

Name: DDR3PHY_BISTRR
Offset: 0x100
Reset: 0x00000000
Property: Read/Write

BIST Run Register is used to trigger the running of built-in-self test routines on both the address/command lane and the date byte lanes.

Bit	31	30	29	28	27	26	25	24
							BCKSEL[2:1]

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 25:23 – BCKSEL[2:0] BIST CK Select
Selects the CK to be used for capturing loopback data on the address/command lane.

Value	Description
000	CK
001	Reserved
010	Reserved
011	Reserved
100	CK#
101	Reserved
110	Reserved
111	Reserved

Bits 20:19 – BDXSEL[1:0] BIST DATX8 Select
Select the byte lane for comparison of loopback/read data. Valid values are 0 to 8.

Bits 18:17 – BDPAT[1:0] BIST Data Pattern
Selects the data pattern used during BIST.

Value	Description
00	Walking 0
01	Walking 1
10	LFSR-based pseudo-random
11	User programmable

Bit 16 – BDMEN BIST Data Mask Enable
Enables if set that the data mask BIST should be included in the BIST run, i.e. data pattern generated and loopback data compared. This is valid only for Loopback mode.

Bit 15 – BACEN BIST AC Enable
Enables the running of BIST on the address/command lane PHY. This bit is exclusive with BDXEN, i.e. both cannot be set to '1' at the same time.

Bit 14 – BDXEN BIST DATX8 Enable
Enables the running of BIST on the data byte lane PHYs. This bit is exclusive with BACEN, i.e. both cannot be set to '1' at the same time.

Bit 13 – BSONF BIST Stop On Nth Fail
Specifies if set that the BIST should stop when an nth data word or address/command comparison error has been encountered.

Bits 12:5 – NFAIL[7:0] Number of Failures
Specifies the number of failures after which the execution of commands and the capture of read data should stop if BSONF bit of this register is set. Execution of commands and the capture of read data will stop after (NFAIL+1) failures if BSONF is set.

Bit 4 – BINF BIST Infinite Run
Specifies if set that the BIST should be run indefinitely until when it is either stopped or a failure has been encountered. Otherwise BIST is run until number of BIST words specified in the BISTWCR register has been generated.

Bit 3 – BMODE BIST Mode
Selects the mode in which BIST is run.

Value	Name	Description
0	Loopback mode	Address, commands and data loop back at the PHY I/Os.
1	DRAM mode	Address, commands and data go to DRAM for normal memory accesses.

Bits 2:0 – BINST[2:0] BIST Instruction
Selects the BIST instruction to be executed.

Value	Name	Description
000	NOP	No operation
001	Run	Triggers the running of the BIST
010	Stop	Stops the running of the BIST
011	Reset	Resets all BIST run-time registers, such as error counters
100-111	–	Reserved

18.4.45 DDR3PHY BIST Word Count Register

Name: DDR3PHY_BISTWCR
Offset: 0x10C
Reset: 0x00000000
Property: Read/Write

BIST Word Count Register is used to specify the number of words to generate during BIST.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 15:0 – BWCNT[15:0] BIST Word Count
Indicates the number of words to generate during BIST. This must be a multiple of DRAM burst length (BL) divided by 2, e.g. for BL=8, valid values are 4, 8, 12, 16, and so on.

18.4.46 DDR3PHY BIST Mask 0 Register

Name: DDR3PHY_BISTMSKR0
Offset: 0x104
Reset: 0x00000000
Property: Read/Write

BIST mask registers are used to disable data comparison on individual data bits of the address/command lane and data byte lane. A bit that is masked will not contribute to the word error counters or bit error counters.

Bit 28 – ODTMSK
Mask bit for ODT.

Bit 24 – CSMSK
Mask bit for CS#.

Bit 20 – CKEMSK
Mask bit for CKE.

Bit 19 – WEMSK
Mask bit for the WE#.

Bits 18:16 – BAMSK[2:0]
Mask bit for each of the up to 3 bank address bits.

Bits 15:0 – AMSK[15:0]
Mask bit for each of the up to 16 address bits.

18.4.47 DDR3PHY BIST Mask 1 Register

Name: DDR3PHY_BISTMSKR1
Offset: 0x108
Reset: 0x00000000
Property: Read/Write

BIST mask registers are used to disable data comparison on individual data bits of the address/command lane and data byte lane. A bit that is masked will not contribute to the word error counters or bit error counters.

Bit 19 – CASMSK
Mask bit for the CAS.

Bit 18 – RASMSK
Mask bit for the RAS.

Bits 17:16 – DMMSK[1:0]
Mask bit for the data mask (DM) bit.

Bits 1:0 – DQMSK[1:0]
Mask bit for each of the 8 data (DQ) bits.

18.4.48 DDR3PHY BIST LFSR Seed Register

Name: DDR3PHY_BISTLSR
Offset: 0x110
Reset: 0x00000000
Property: Read/Write

BIST LFSR Seed Register specifies the seed for generating pseudo-random BIST patterns.

Bit	31	30	29	28	27	26	25	24
	SEED[31:24]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Reset	0	0	0	0	0	0	0	0

Bits 31:0 – SEED[31:0]
LFSR seed for pseudo-random BIST patterns.

18.4.49 DDR3PHY BIST Address 0 Register

Name: DDR3PHY_BISTAR0
Offset: 0x114
Reset: 0x00000000
Property: Read/Write

BIST address registers specify the starting address and address increment used during BIST when in DRAM mode. The BIST address is based on a decoded bank/row/column address. The user should ensure the column address starts at the beginning of a burst boundary. For example, for BL8, A[2:0] = DTCOL[2:0] = 0.

Bit	31	30	29	28	27	26	25	24

Reset	0	0	0	0	0	0	0	0

Bits 30:28 – BBANK[2:0] BIST Bank Address
Selects the SDRAM bank address to be used during BIST.

Bits 27:12 – BROW[15:0] BIST Row Address
Selects the SDRAM row address to be used during BIST.

Bits 11:0 – BCOL[11:0] BIST Column Address
Selects the SDRAM column address to be used during BIST. The lower bits of this address must be “0000” for BL16, “000” for BL8, “00” for BL4 and “0” for BL2.

18.4.50 DDR3PHY BIST Address 1 Register

Name: DDR3PHY_BISTAR1
Offset: 0x118
Reset: 0x00000000
Property: Read/Write

BIST address registers specify the starting address and address increment used during BIST when in DRAM mode. The BIST address is based on a decoded bank/row/column address. The user should ensure the column address starts at the beginning of a burst boundary. For example, for BL8, A[2:0] = DTCOL[2:0] = 0.

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 15:4 – BAINC[11:0] BIST Address Increment
Selects the value by which the SDRAM address is incremented for each write/read access. This value must be at the beginning of a burst boundary, i.e. the lower bits must be “0000” for BL16, “000” for BL8, “00” for BL4 and “0” for BL2.

Bits 3:2 – BMRANK[1:0] BIST Maximum Rank
Maximum SDRAM rank to be used during BIST. Write to 0 (only one rank).

Bits 1:0 – BRANK[1:0] BIST Rank
SDRAM rank to be used during BIST. Write to 0 (only one rank).

18.4.51 DDR3PHY BIST Address 2 Register

Name: DDR3PHY_BISTAR2
Offset: 0x11C
Reset: 0x00000000
Property: Read/Write

BIST address registers specify the starting address and address increment used during BIST when in DRAM mode. The BIST address is based on a decoded bank/row/column address. The user should ensure the column address starts at the beginning of a burst boundary. For example, for BL8, A[2:0] = DTCOL[2:0] = 0.

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 30:28 – BMBANK[2:0] BIST Maximum Bank Address
Specifies the maximum SDRAM bank address to be used during BIST before the address increments to the next rank.

Bits 27:12 – BMROW[15:0] BIST Maximum Row Address
Specifies the maximum SDRAM row address to be used during BIST before the address increments to the next bank.

Bits 11:0 – BMCOL[11:0] BIST Maximum Column Address
Specifies the maximum SDRAM column address to be used during BIST before the address increments to the next row.

18.4.52 DDR3PHY BIST User Data Pattern Register

Name: DDR3PHY_BISTUDPR
Offset: 0x120
Reset: 0x00000000
Property: Read/Write

This register specifies the user data pattern to be used during BIST. The pattern transmitted on DQ[2*n] is BUDP0[0] on the first beat, BUDP0[1] on the second beat and so on. BUDP1 is transmitted on DQ[2*n+1] in a similar way. After the 16th beat, the data pattern wraps around and is repeated until BIST is stopped.

Bits 31:16 – BUDP1[15:0] BIST User Data Pattern 1
Data to be applied on odd DQ pins during BIST.

Bits 15:0 – BUDP0[15:0] BIST User Data Pattern 0
Data to be applied on even DQ pins during BIST.

18.4.53 DDR3PHY General Status Register

Name: DDR3PHY_BISTGSR
Offset: 0x124
Reset: 0x00000000
Property: Read/Write

BIST General Status Register is used to return miscellaneous status of the BIST engine, including done status.

Bit	31	30	29	28	27	26	25	24
	CASBER[1:0]		RASBER[1:0]		DMBER[3:0]			
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	7	6	5	4	3	2	1	0
						BDXERR	BACERR	BDONE
Access						R/W	R/W	R/W
Reset						0	0	0

Bits 31:30 – CASBER[1:0] CAS Bit Error
Indicates the number of bit errors on CAS.

Bits 29:28 – RASBER[1:0] RAS Bit Error
Indicates the number of bit errors on RAS.

Bits 27:24 – DMBER[3:0] DM Bit Error
Indicates the number of bit errors on data mask (DM) bit. DMBER[1:0] are for the first DM beat, and DMBER[3:2] are for the second DM beat.

Bit 2 – BDXERR BIST Data Error
Indicates if set that there is a data comparison error in the byte lane.

Bit 1 – BACERR BIST Address/Command Error
Indicates if set that there is a data comparison error in the address/command lane.

Bit 0 – BDONE BIST Done
Indicates if set that the BIST has finished executing. This bit is reset to zero when BIST is triggered.

18.4.54 DDR3PHY Word Error Register

Name: DDR3PHY_BISTWER
Offset: 0x128
Reset: 0x00000000
Property: Read/Write

BIST Word Error Register is used to return the number of errors on the full word (all bits) of the address/command lane and data byte lane. An error on any bit of the address/command bus will increment the address/command word error count. Similarly any error on the data bits or data mask bits will increment the data byte lane word error count.

Bit	31	30	29	28	27	26	25	24
	DXWER[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 31:16 – DXWER[15:0] Byte Word Error
Indicates the number of word errors on the byte lane. An error on any bit of the data bus including the data mask bit increments the error count.

Bits 15:0 – ACWER[15:0] Address/Command Word Error
Indicates the number of word errors on the address/command lane. An error on any bit of the address/command bus increments the error count.

18.4.55 DDR3PHY BIST Bit Error 0 Register

Name: DDR3PHY_BISTBER0
Offset: 0x12C
Reset: 0x00000000
Property: Read/Write

BIST error registers are used to return the number of errors on individual data bits of the address/command lane and data byte lane. Bit error registers only return up to 4 errors on the address/command bits and up to 8 errors on the data bits. To diagnose more errors on a bit, use the BIST mask registers to mask all but the bit of interest and re-run the BIST. In this case the word error counter is equal to the bit error counter.

Bit 28 – ODTWEBS
Bit status during a word error for ODT bits.

Bit 24 – CSWEBS
Bit status during a word error for CS# bits.

Bit 20 – CKEWEBS
Bit status during a word error for CKE bits.

Bit 19 – WEWEBS
Bit status during a word error for the WE#.

Bits 18:16 – BAWEBS[2:0]
Bit status during a word error for each of the up to 3 bank address bits.

Bits 15:0 – AWEBS[15:0]
Bit status during a word error for each of the up to 16 address bits.

18.4.60 DDR3PHY Fail Word 1 Register

Name: DDR3PHY_BISTFWR1
Offset: 0x140
Reset: 0x00000000
Property: Read/Write

BIST fail word registers are used to return the last failing word of the address/command lane and data byte lane.

Bit	31	30	29	28	27	26	25	24
Access

Bit 19 – CASWEBS
Bit status during a word error for the CAS.

Bit 18 – RASWEBS
Bit status during a word error for the RAS.

Bits 17:16 – DMWEBS[1:0]
Bit status during a word error for the data mask (DM) bit. DMWEBS [0] is for the first DM beat, and DMWEBS [1] is for the second DM beat.

Bits 15:0 – DQWEBS[15:0]
Bit status during a word error for each of the 8 data (DQ) bits. The first 8 bits indicate the status of the first data beat (i.e. the status of the data driven out on DQ[7:0] on the rising edge of DQS). The second 8 bits indicate the status of the second data beat (i.e. the status of the data driven out on DQ[7:0] on the falling edge of DQS). For each of the 8-bit group, the first bit is for DQ[0], the second bit is for DQ[1], and so on.

18.4.61 DDR3PHY ZQ Impedance Control Register 0

Name: DDR3PHY_ZQ0CR0
Offset: 0x180
Reset: 0x00000000
Property: Read/Write

These registers are used for impedance control and calibration to enable the programmable and PVT-compensated on-die termination (ODT) and output impedance of the functional SSTL cells.

Bit 31 – ZQPD ZQ Power Down
Powers down, if set, the PZQ cell. Not applicable to D3A I/Os.

Bit 30 – ZCAL Impedance Calibration Trigger
A write of '1' to this bit triggers impedance calibration to be performed by the impedance control logic. The impedance calibration trigger bit is self-clearing and returns back to '0' when the calibration is complete. Note: If ZDEN is set, then the ZCAL bit should be set to 0.

Bit 29 – ZCALBYP Impedance Calibration Bypass
Disables, if set, impedance calibration of this ZQ control block when impedance calibration is triggered globally using the ZCAL bit of PIR. Impedance calibration of this ZQ block may be triggered manually using ZCAL.

Bit 28 – ZDEN Impedance Over-Ride Enable
When this bit is set, it allows users to directly drive the impedance control using the data programmed in the ZQDATA field. Otherwise, the control is generated automatically by the impedance control logic. Note: If ZDEN is set, then the ZCAL bit should be set to 0.

Bits 27:0 – ZDATA[27:0] Impedance Over-Ride Data
Data used to directly drive the impedance control. Field mapping is as follows:

[27:20]	Reserved, returns zeros on reads
[19:15]	Pull-up on-die termination impedance select
[14:10]	Pull-down on-die termination impedance select
[9:5]	Pull-up output impedance select
[4:0]	Pull-down output impedance select

18.4.62 DDR3PHY ZQ Impedance Control Register 1

Name: DDR3PHY_ZQ0CR1
Offset: 0x184
Reset: 0x00000000
Property: Read/Write

These registers are used for impedance control and calibration to enable the programmable and PVT-compensated on-die termination (ODT) and output impedance of the functional SSTL cells.

Bit 31 – ZDONE Impedance Calibration Done
Indicates that impedance calibration has completed.

Bit 30 – ZERR Impedance Calibration Error
If set, indicates that there was an error during impedance calibration.

Bits 27:0 – ZCTRL[27:0] Impedance Control
Current value of impedance control. Field mapping is as follows:

[27:20]	Reserved, returns zeros on reads
[19:15]	Pull-up on-die termination impedance select
[14:10]	Pull-down on-die termination impedance select
[9:5]	Pull-up output impedance select
[4:0]	Pull-down output impedance select

18.4.64 DDR3PHY ZQ Status Register 1

Name: DDR3PHY_ZQ0SR1
Offset: 0x18C
Reset: 0x00000000
Property: Read/Write

These registers are used to provide the status for impedance control and calibration to enable the programmable and PVT-compensated on-die termination (ODT) and output impedance of the functional SSTL cells.

Similar status encodings as ZPD.

Bits 3:2 – ZPU[1:0] Output Impedance Pull-Up Calibration Status
Similar status encodings as ZPD.

Bits 1:0 – ZPD[1:0] Output Impedance Pull-Down Calibration Status
Valid status encodings are:

00	Completed with no errors
01	Overflow error
10	Underflow error
11	Calibration in progress

18.4.65 DDR3PHY DATX8 General Configuration Register

Name: DDR3PHY_DXxGCR
Offset: 0x01C0 + x*0x40 [x=0..1]
Reset: 0x00000000
Property: Read/Write

This register is used for miscellaneous configurations specific to a particular instantiation of the DATX8 macro. For D3A I/Os, the IOM register bits connect to the I/O IDDQ pins. Furthermore, the I/O power-down register bits (PDD, and PDR, and PD) fields have no relevance for D3A I/Os.

Bit	31	30	29	28	27	26	25	24
Access

	R0RVSL[1:0]		RTTOAL	RTTOH[1:0]		DQRTT	DQSRTT	DSEN[1]
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	DSEN[0]	DQSRPD	DXPDR	DXPDD	DXIOM	DQODT	DQSODT	DXEN
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 16:14 – R0RVSL[2:0] Rank 0 ITMD Read Valid System Latency
Used to specify the read valid system latency relative to the ideal placement of the ITMD read valid signal when DXCCR.RVSEL is set to 0. Power-up default is 011 (i.e. ideal placement of the read valid signal). The RVSL field is initially set by the PUB during automatic read valid training but this value can be overwritten by a direct write to this register.

Value	Description
000	Read valid system latency = ideal placement - 3
001	Read valid system latency = ideal placement - 2
010	Read valid system latency = ideal placement - 1
011	Read valid system latency = ideal placement
100	Read valid system latency = ideal placement + 1
101	Read valid system latency = ideal placement + 2
110	Read valid system latency = ideal placement +3
111	Reserved

Bit 13 – RTTOAL RTT On Additive Latency
Indicates when the ODT control of DQ/DQS SSTL I/Os is set to the value in DQODT/DQSODT during read cycles.

Value	Description
0	ODT control is set to DQSODT/DQODT almost two cycles before read data preamble.
1	ODT control is set to DQSODT/DQODT almost one cycle before read data preamble.

Bits 12:11 – RTTOH[1:0] RTT Output Hold
Indicates the number of clock cycles (from 0 to 3) after the read data postamble for which ODT control should remain set to DQSODT for DQS or DQODT for DQ/DM before disabling it (setting it to '0') when using dynamic ODT control. ODT is disabled almost RTTOH clock cycles after the read postamble.

Bit 10 – DQRTT DQ Dynamic RTT Control
Indicates, if set, that the ODT control of DQ/DM SSTL I/Os be dynamically controlled by setting it to the value in DQODT during reads and disabling it (setting it to '0') during any other cycle. If this bit is not set, then the ODT control of DQ SSTL I/Os is always set to the value in DQODT. Since dynamic ODT is on by default, when using LPDDR2/LPDDR3 this bit must be set to 0 since LPDDR2/LPDDR3 does not require ODT to be on.

Bit 9 – DQSRTT DQS Dynamic RTT Control
Indicates, if set, that the ODT control of DQS SSTL I/Os be dynamically controlled by setting it to the value in DQSODT during reads and disabling it (setting it to '0') during any other cycle. If this bit is not set, then the ODT control of DQS SSTL I/Os is always set to the value in DQSODT field. Since dynamic ODT is on by default, when using LPDDR2/LPDDR3 this bit must be set to 0 since LPDDR2/LPDDR3 does not require ODT to be on.

Bits 8:7 – DSEN[1:0] Write DQS Enable
Controls whether the write DQS going to the SDRAM is enabled (toggling) or disabled (static value) and whether the DQS is inverted. DQS# is always the inversion of DQS. These values are valid only when DQS/DQS# output enable is on, otherwise the DQS/DQS# is tristated.

Value	Description
00	DQS disabled (driven to constant 0)
01	DQS toggling with normal polarity (this should be the default setting)
10	DQS toggling with inverted polarity
11	DQS disabled (driven to constant 1)

Bit 6 – DQSRPD DQSR Power Down
Powers down, if set, the PDQSR cell. This bit is ORed with the common PDR configuration bit (see 18.4.10. DDR3PHY_DXCCR).

Bit 5 – DXPDR Data Power Down Receiver
Powers down, when set, the input receiver on I/O for DQ, DM, and DQS/DQS# pins of the byte. This bit is ORed with the common PDR configuration bit (see 18.4.10. DDR3PHY_DXCCR).

Bit 4 – DXPDD Data Power Down Driver
Powers down, when set, the output driver on I/O for DQ, DM, and DQS/DQS# pins of the byte. This bit is ORed with the common PDD configuration bit (see 18.4.10. DDR3PHY_DXCCR).

Bit 3 – DXIOM Data I/O Mode
Selects SSTL mode (when set to 0) or CMOS mode (when set to 1) of the I/O for DQ, DM, and DQS/DQS# pins of the byte. This bit is ORed with the IOM configuration bit of the individual DATX8 (see 18.4.10. DDR3PHY_DXCCR).

Bit 2 – DQODT Data On-Die Termination
Enables, when set, the on-die termination on the I/O for DQ and DM pins of the byte. This bit is ORed with the common DATX8 ODT configuration bit (see 18.4.10. DDR3PHY_DXCCR).

Bit 1 – DQSODT DQS On-Die Termination
Enables, when set, the on-die termination on the I/O for DQS/DQS# pin of the byte. This bit is ORed with the common DATX8 ODT configuration bit (see 18.4.10. DDR3PHY_DXCCR).

Bit 0 – DXEN Data Byte Enable
Enables, if set, the DATX8 and SSTL I/Os used on the data byte. Setting this bit to '0' disables the byte, i.e. the byte SSTL I/Os are put in Power-Down mode and the DLL in the DATX8 is put in Bypass mode. After changing a Byte Lane from disabled to enabled, the DLL for that Byte Lane must be reset and re-locked. Software can use the PIR registers DLLSRST and DLLLOCK to accomplish this (reset and re-locks all DLLs in the DDR PHY).

18.4.66 DDR3PHY DATX8 General Status Register 0

Name: DDR3PHY_DXxGSR0
Offset: 0x01C4 + x*0x40 [x=0..1]
Reset: 0x00000000
Property: Read/Write

This is a general status register for the DATX8. They indicate among other things DQS drift and data training status.

Bit	31	30	29	28	27	26	25	24
Access

Reset				0				0

Bits 15:13 – DTPASS[2:0] DQS GateTraining Pass Count
The number of passing configurations during DQS gate training.

Bit 8 – DTIERR DQS Gate Training Intermittent Error
If set, indicates that there was an intermittent error during DQS gate training of the byte, such as a pass was followed by a fail then followed by another pass.

Bit 4 – DTERR DQS Gate Training Error
If set, indicates that a valid DQS gating window could not be found during DQS gate training of the byte.

Bit 0 – DTDONE Data Training Done
Indicates, if set, that the byte has finished doing data training.

18.4.67 DDR3PHY DATX8 General Status Register 1

Name: DDR3PHY_DXxGSR1
Offset: 0x01C8 + x*0x40 [x=0..1]
Reset: 0x00000000
Property: Read/Write

This is a general status register for the DATX8. They indicate among other things DQS drift and data training status.

Bits 21:20 – RVPASS[1:0] Read Valid Training Pass Count
The number of passing configurations during read valid training.

Bit 16 – RVIERR Read Valid Training Intermittent Error
If set, indicates that there was an intermittent error during read valid training of the byte, such as a pass was followed by a fail then followed by another pass.

Bit 12 – RVERR Read Valid Training Error
If set, indicates that a valid read valid placement could not be found during read valid training of the byte.

Bits 5:4 – DQSDFT[1:0] DQS Drift
Used to report the drift on the read data strobe of the data byte.

Value	Description
`00`	No drift
`01`	90° drift
`10`	180° drift
`11`	270° drift or more

Bit 0 – DFTERR DQS Drift Error
If set, indicates that the byte read data strobe has drifted by more than or equal to the drift limit set in the PHY General Configuration Register (PGCR).

18.4.68 DDR3PHY DATX8 DLL Control Register

Name: DDR3PHY_DXxDLLCR
Offset: 0x01CC + x*0x40 [x=0..1]
Reset: 0x00000000
Property: Read/Write

DATX8 DLL Control Register is used to control the DLL on the byte lane.

Bit	31	30	29	28	27	26	25	24

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit 31 – DLLDIS DLL Disable
A disabled DLL is bypassed. Default ('0') is DLL enabled.

Bit 30 – DLLSRST DLL Soft Reset
Soft resets the byte DLL by driving the DLL soft reset pin.

Bit 19 – SDLBMODE Client DLL Loopback Mode
If this bit is set, the client DLL is put in Loopback mode in which there is no 90 degrees phase shift on read DQS/DQS#. This bit must be set when operating the byte PHYs in Loopback mode such as during BIST loopback.

Bit 18 – ATESTEN Analog Test Enable
Enables the analog test signal to be output on the DLL analog test output (test_out_a). The DLL analog test output is tri-stated when this bit is '0'.

Bits 17:14 – SDPHASE[3:0] Client DLL Phase Trim
Selects the phase difference between the input clock and the corresponding output clock of the client DLL.

Value	Description
`0000`	90
`0001`	72
`0010`	54
`0011`	36
`0100`	108
`0101`	90

1100	144
1101	126
1110	108
1111	90

Bits 13:12 – SSTART[1:0] Client Auto Start-Up
Used to control how the client DLL starts up relative to the host DLL locking.

Value	Description
0X	Client DLL automatically starts up once the host DLL has achieved lock.
10	The automatic startup of the client DLL is disabled; the phase detector is disabled.
11	The automatic startup of the client DLL is disabled; the phase detector is enabled.

Bits 11:9 – MFWDLY[2:0] Host Feed-Forward Delay Trim
Used to trim the delay in the host DLL feed-forward path.

Value	Description
000	Minimum delay
111	Maximum delay

Bits 8:6 – MFBDLY[2:0] Host Feed-Back Delay Trim
Used to trim the delay in the host DLL feedback path.

Value	Description
000	Minimum delay
111	Maximum delay

Bits 5:3 – SFWDLY[2:0] Client Feed-Forward Delay Trim
Used to trim the delay in the client DLL feed-forward path.

Value	Description
000	Minimum delay
111	Maximum delay

Bits 2:0 – SFBDLY[2:0] Client Feed-Back Delay Trim
Used to trim the delay in the client DLL feedback path.

Value	Description
000	Minimum delay
111	Maximum delay

18.4.69 DDR3PHY DATX8 DQ Timing Register

Name: DDR3PHY_DXxDQTR
Offset: 0x01D0 + x*0x40 [x=0..1]
Reset: 0x00000000
Property: Read/Write

This register is used to tune the delays within the ITMs on each data bit to maximize the data eye during reads from the SDRAM. The default settings for this register ensure the delay on each data bit is matched to the delay of the data strobe through the client DLL and clock tree. These settings provide optimal alignment for these signal inputs on the ITMD cell. The DQTR register allows this delay to be slightly decreased.

The PHY is designed such that the default delay setting results in the optimal timing. Users may attempt to fine-tune the DQ/DQS relationship further by modifying these registers. If users elect to modify these registers, use of a modified data training sequence is suggested to find the optimum setting.

Bits 0:3, 4:7 – DQDLYx DQ Delay
Used to adjust the delay of the data relative to the nominal delay that is matched to the delay of the data strobes through the client DLL and clock tree. DQDLY0 controls the delay of data bit [0], DQDLY1 controls data bit [1].

Value	Description
`00`	Nominal delay
`01`	Nominal delay + 1 step
`10`	Nominal delay + 2 steps
`11`	Nominal delay + 3 steps

18.4.70 DDR3PHY DATX8 DQS Timing Register

Name: DDR3PHY_DXxDQSTR
Offset: 0x01D4 + x*0x40 [x=0..1]
Reset: 0x00000000
Property: Read/Write

This register is used to control the timing of the DQS gating. It is also used to tune the delays within the ITMs on each DQS/DQS_b strobe to maximize the data eye during reads from the SDRAM. Usually, the delay on each data strobe is matched to the delay of the data bit through the client DLL and clock tree. The DQSTR register allows this delay to be slightly increased or decreased.

The PHY is designed such that the nominal delay setting results in the optimal timing. Users may attempt to fine-tune the DQ/DQS relationship further by modifying these registers. If users elect to modify these registers, use of a modified data training sequence is suggested to find the optimum setting.

						R0DGSL[2:0]		
Access						R/W	R/W	R/W
Reset						0	0	0

Bits 25:23 – DQSNDLY[2:0] DQS# Delay
Used to adjust the delay of the data strobes relative to the nominal delay that is matched to the delay of the data bit through the client DLL and clock tree. DQSDLY controls the delay on DQS strobe and DQSNDLY controls the delay on DQS#.
Note: After changing this value, an ITM soft reset (PIR.ITMSRST=1, plus PIR.INIT=1) must be issued.

Value	Description
000	Nominal delay - 3 steps
001	Nominal delay - 2 steps
010	Nominal delay - 1 step
011	Nominal delay
100	Nominal delay + 1 step
101	Nominal delay + 2 steps
110	Nominal delay + 3 steps
111	Nominal delay + 4 steps

Bits 25:23 – DMDLY[2:0] DM Delay
Used to adjust the delay of the data mask relative to the nominal delay that is matched to the delay of the data strobes through the client DLL and clock tree. The lower two bits of the DQMDLY controls the delay for the data clocked by DQS, while the higher two bits control the delay for the data clocked by DQS_b.

Value	Description
00	Nominal delay

Value	Description
01	Nominal delay + 1 step
10	Nominal delay + 2 steps
11	Nominal delay + 3 steps

Bits 22:20 – DQSDLY[2:0] DQS Delay
Used to adjust the delay of the data strobes relative to the nominal delay that is matched to the delay of the data bit through the client DLL and clock tree. DQSDLY controls the delay on DQS strobe and DQSNDLY controls the delay on DQS#.
Note: After changing this value, an ITM soft reset (PIR.ITMSRST=1, plus PIR.INIT=1) must be issued.

Value	Description
000	Nominal delay - 3 steps
001	Nominal delay - 2 steps
010	Nominal delay - 1 step
011	Nominal delay
100	Nominal delay + 1 step
101	Nominal delay + 2 steps
110	Nominal delay + 3 steps
111	Nominal delay + 4 steps

Bits 13:12 – R0DGPS[1:0] Rank 0 DQS Gating Phase Select
Selects the clock used to enable the data strobes during read so that the value of the data strobes before and after the preamble/postamble are filtered out. The R0DGPS field is initially set by the PUBL during automatic DQS data training and subsequently updated during data strobe drift compensation. However, this value can be overwritten by a direct write to this register, and the automatic update during DQS drift compensation can be disabled using DDR3PHY_PGCR.

Value	Description
00	90° clock (clk90)
01	180° clock (clk180)
10	270° clock (clk270)
11	360° clock (clk0)

Bits 2:0 – R0DGSL[2:0] Rank 0 DQS Gating System Latency
Used to increase the number of clock cycles needed to expect valid DDR read data by up to five extra clock cycles. This is used to compensate for board delays and other system delays. Power-up default is 000 (i.e. no extra clock cycles required). The SL field is initially set by the PUBL during automatic DQS data training but this value can be overwritten by a direct write to this register.

Value	Description
000	No extra clock cycles
001	1 extra clock cycle
010	2 extra clock cycles
011	3 extra clock cycles
100	4 extra clock cycles
101	5 extra clock cycles
110	Reserved
111	Reserved

19. Boot Strategies

19.1 Standard Boot Strategies

19.1.1 Overview

By default, the chip starts in Standard Boot mode. See Secure Boot Strategies for details on Secure Boot mode enabling.

The system always boots from the ROM memory at address 0x0.

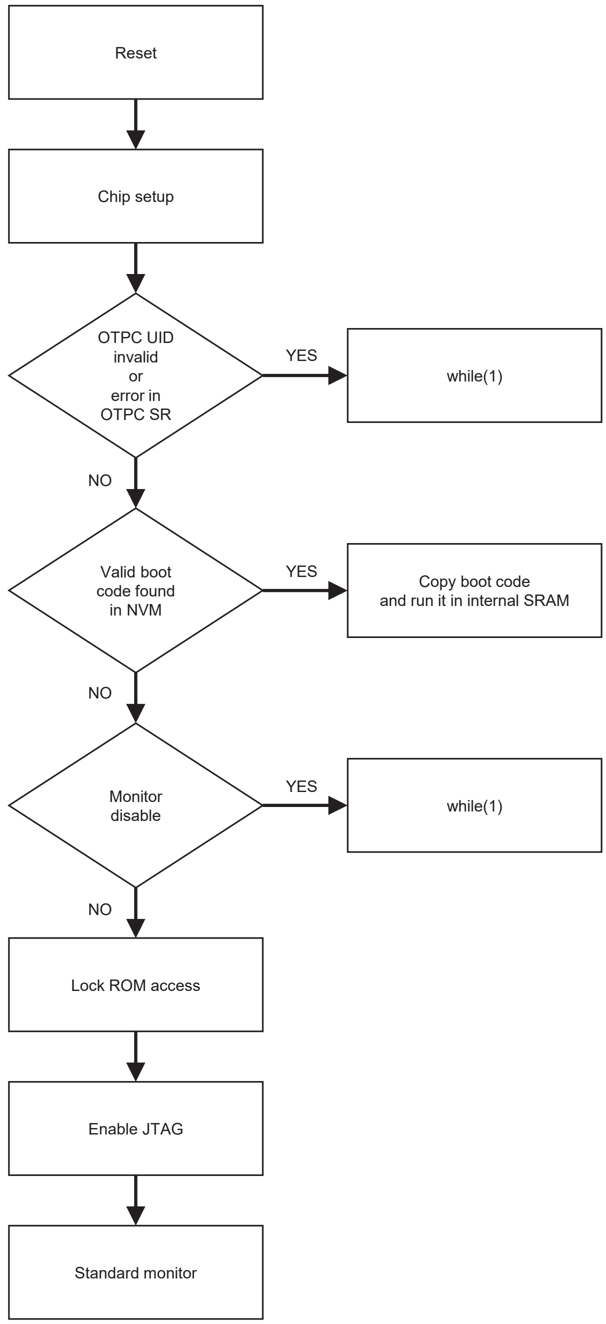
The ROM code is a boot program contained in the embedded ROM. It is also called “Bootloader”.

Note: JTAG access is disabled during execution of the ROM code. It is enabled when jumping into SRAM when a valid code has been found on an external Non-Volatile Memory (NVM) at the same time the ROM memory access is locked. If no valid bootstrap is found on an external NVM, the ROM code enables the USB connection and one UART serial port, starts the standard monitor, locks access to the ROM memory and enables the JTAG connection.

19.1.2 Flow Diagram

The following figure shows the ROM code global flow.

Figure 19-1. ROM Code Flow Diagram



19.1.3 Chip Setup

When the chip is powered on, the processor clock (CPU_CLK) and the main system bus clock (MCK0) source is the main clock (MAINCK), which is fed by the main RC oscillator.

The ROM code performs a low-level initialization that follows the steps described below:

1. SYSPLL is initialized.

2. MCK1 is initialized and sourced by SYSPLL.
3. MCK4 is initialized and sourced by SYSPLL.
4. CPUPLL is initialized.
5. When the CPUPLL is stabilized, the main system bus clock (MCK0) source is switched from the main clock (MAINCK) to the CPUPLL clock. The CPU_CLK frequency is the same as the CPUPLL clock, whereas the MCK0 frequency is the quarter of the CPUPLL clock.

For clock frequencies, see the table Clock Frequencies During External Memory Boot Sequence.

Note: No external crystal or clock is needed during the external boot memories sequence. An external clock source is checked before the launch of the monitor to get a more accurate clock signal for USB.

19.1.4 Standard Boot Configuration

The boot sequence is controlled using the Boot Configuration Packet, stored in the OTP User area and configured through the OTP Controller (refer to OTP Memory Controller (OTPC)).

19.1.4.1 Default Boot Sequence

When no Boot Configuration Packet is available in the OTP User area, the ROM code uses the following settings:

- FLEXCOM3 IOSET 5 is used as a console.
- Boot from SDMMC1 IOSET1 (uses card detect pin)

If no valid code is found in the SD Card or e.MMC, the ROM code goes to the standard monitor.

See the table PIO Driven during Boot Program Execution for further details about PIO settings.

19.1.4.2 Boot Configuration Packet

The boot configuration data are stored in the Boot Configuration Packet in the OTP User area. These data can be used for various boot sequence customizations:

- Enable and configure the boot from selected memories
- Configure the UART port used as a console
- Disable monitor

See Boot Configuration User Interface for a detailed description of all the fields in these data.

Out of factory, the OTP memory is empty. No Boot Configuration Packet is written. During the prototyping phase, the Boot Configuration Packet can be created and stored in a backed up OTP emulation SRAM to avoid an OTP permanent write. To enable this feature, the bit BSC_CR.EMUL_EN must be set. Note that once a real packet has been written in OTP User Area, the Emulation mode cannot be used anymore.

The current running mode of the OTP can be observed by reading BSC_CR.EMUL_EN. If this bit is set, the OTP Emulation mode is enabled, otherwise it is disabled.

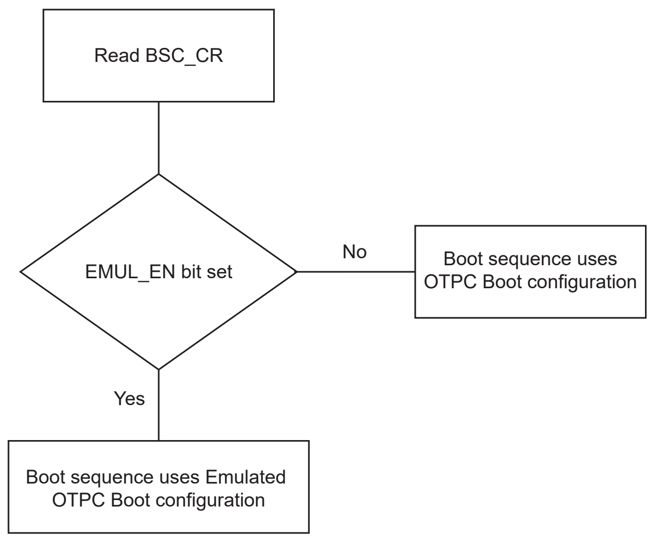
After a reset, the ROM code reads the Boot Configuration Packet from the OTP emulation SRAM if the bit BSC_CR.EMUL_EN is set to 1. Otherwise, the packet is read from the OTP matrix.

The OTP Emulation mode enables the user to test several boot configuration options, including Secure Boot Mode (see Secure Boot Strategies), without programming permanently the OTP.

Note: The OTP emulation SRAM is backed up. So, if the VDDBU power is supplied, the boot configuration is kept when the chip in not powered on.

⚠WARNING The Boot Configuration Packet must be the very first packet to be written in OTP (not in Emulation mode).

Figure 19-2. Boot Configuration Loading



19.1.4.3 Boot Sequence Controller Configuration Register

Name: BSC_CR
Address: 0xE001D054

Bit	31	30	29	28	27	26	25	24
	WPKEY[15:8]							
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
	WPKEY[7:0]							
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
								EMUL_EN
Access								
Reset								

Bits 31:16 – WPKEY[15:0] Write Protect Key

Value	Name	Description
0x6683	PASSWD	Writing any other value in this field aborts the write operation of the BOOT field. Always reads as 0.

Bit 0 – EMUL_EN Emulation Enable

Value	Description
0	Emulation mode is disabled.
1	The OTP user area is emulated in internal SRAM1.

19.1.4.4 Boot Configuration User Interface

Table 19-1. Boot Configuration Packet

Offset	Name	Description
0x00	MON_DIS	Disables monitor
0x04	RESERVED	Reserved
0x08	CONSOLE_PIN	Console pin muxing
0x0C-0x44	MEM_CFGx[2]	Two 32-bit words used to set memory configurations for x=0..6 MEM_CFGx[0]: this word contains mandatory options for all connected memories. MEM_CFGx[1]: this word contains mandatory options for specific memories.

19.1.4.5 Monitor Disable

Name: MON_DIS

Bit	31	30	29	28	27	26	25	24
	DISABLE_MONITOR[31:24]							
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
	DISABLE_MONITOR[23:16]							
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
	DISABLE_MONITOR[15:8]							
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
	DISABLE_MONITOR[7:0]							
Access								
Reset								

Bits 31:0 – DISABLE_MONITOR[31:0] Monitor Disable

Value	Description
`0`	If no boot file is found, launches the monitor.
`Non-Zero`	The monitor is never launched.

19.1.4.6 Console Pin Muxing

Name: CONSOLE_PIN

WARNING To avoid any malfunctioning, the user must not write the "DO NOT USE (DNU)" bits.

Bit	31	30	29	28	27	26	25	24

	ENABLE	DNU	DNU	DNU	DNU	DNU	DNU	DNU
Access								
Reset								

Bits 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31 – DNU DO NOT USE

Bits 15:8 – WPKEY[7:0] Write Protect Key

Value	Name	Description
`0x96`	PASSWD	If any other value is written in this field, all the other bit values are ignored.

Bit 7 – ENABLE Card Detect Enable

Value	Description
`0`	Card detect disable, the ROM code does not use any card detect pin and directly tries to boot from the memory connected to the SDMMC controller.
`1`	Card detect enable, the ROM code checks the level of the card detect pin. If the level is 0, the ROM code tries to boot from the memory connected to the SDMMC controller. If the level is 1, the ROM code skips the SDMMC controller and jumps to the next interface in the boot sequence.

Bits 0, 1, 2, 3, 4, 5, 6 – DNU DO NOT USE

19.1.4.11 NVM Boot Sequence

The ROM code performs the initialization and valid code detection for external memories as described below when the memory interface boot is enabled in the Boot Configuration packet.

Figure 19-3. NVM Boot Sequence

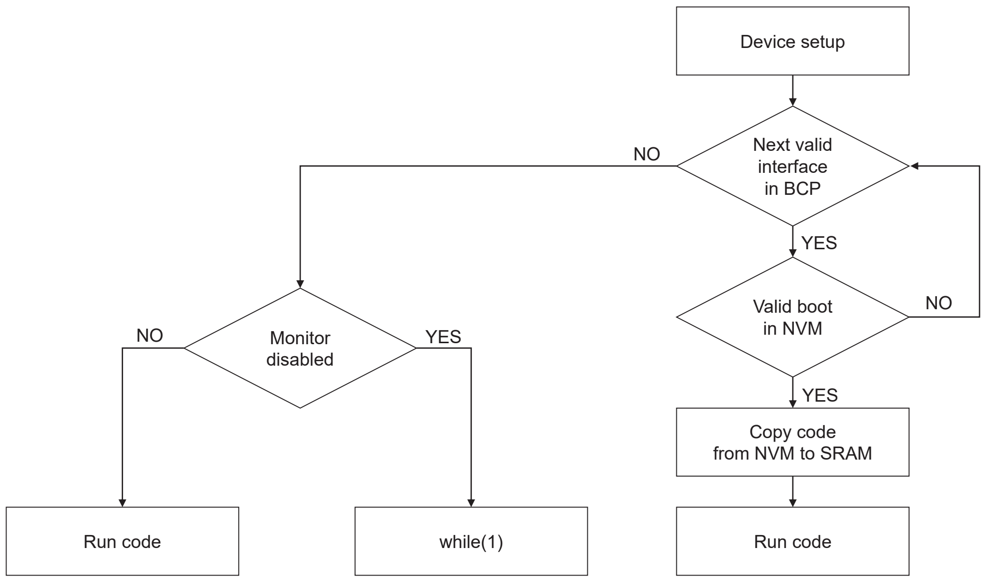

Figure 19-4. NVM Boot Diagram

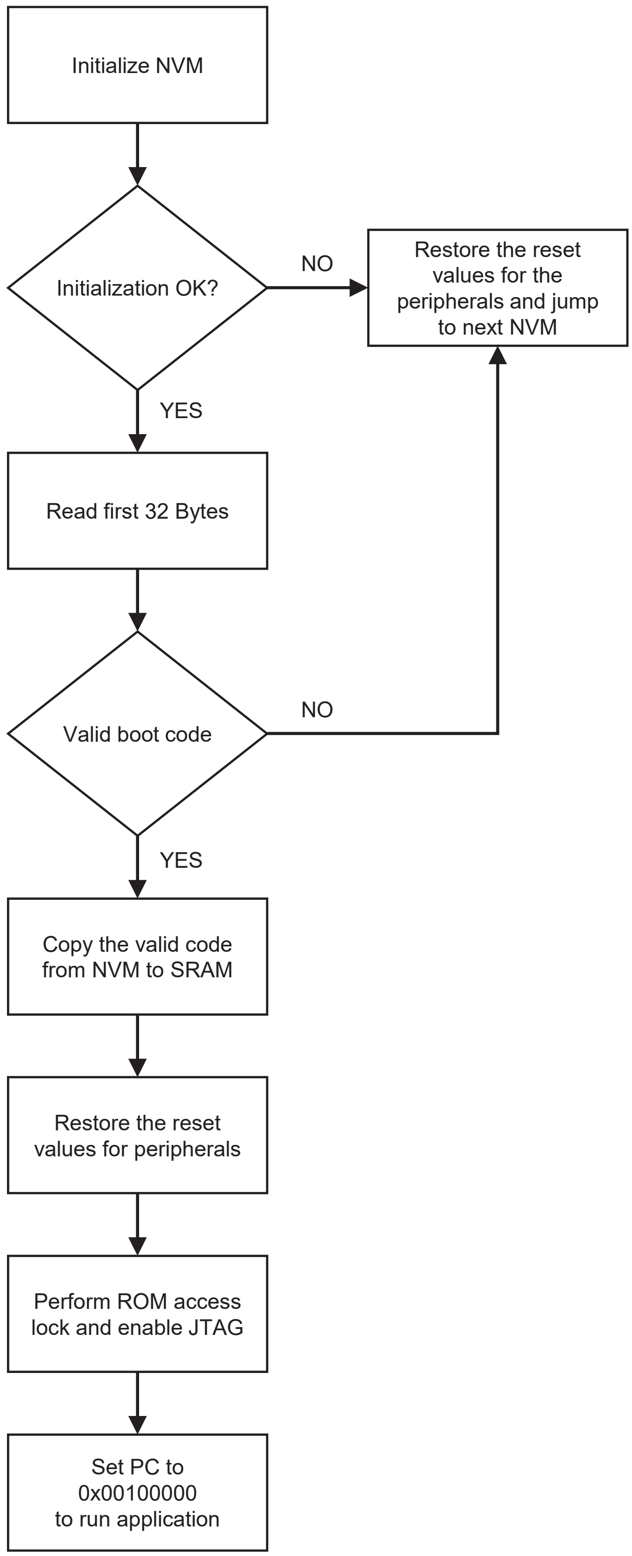

19.1.4.12 Valid Code Detection

Two types of valid code detection are available:

- Arm Exception Vector Check
- boot.bin File Check

19.1.4.12.1 Arm Exception Vector Check

The ROM code analyzes the first 28 bytes corresponding to the first seven Arm exception vectors. Except for the sixth vector, these bytes must implement the Arm instructions for either branch or load PC with PC-relative addressing.

Figure 19-5. LDR Opcode

31			28	27			24	23			20	19 … 16	15 … 12	11 … 0
1	1	1	0	0	1	I	P	U	1	W	0	Rn	Rd	Offset

Figure 19-6. B Opcode

31			28	27			24	23 … 0
1	1	1	0	1	0	1	0	Offset (24 bits)

Unconditional instruction: 0xE for bits 31 to 28.

Load PC with the PC-relative addressing instruction:

- Rn = Rd = PC = 0xF
- I==0 (12-bit immediate value)
- P==1 (pre-indexed)
- U offset added (U==1) or subtracted (U==0)
- W==1

The sixth vector, at offset 0x14, contains the size of the image to download. The user must replace this vector with the user's own vector. This procedure is described below.

Figure 19-7. Arm Vector 6 Structure

31 … 0
Size of the code to download in bytes

The value must be lower than 64 Kbytes

The following is an example of valid vectors:

```
00          ea000006                B 0x20
04          eafffffe                B 0x04
08          eafffffe                B 0x08
0c          eafffffe                B 0x0c
10          eafffffe                B 0x10
14          00001234                ← Code size = 4660 bytes
18          eafffffe                B 0x18
```

19.1.4.12.2 boot.bin File Check

This method is the one used on FAT-formatted SD Card and e.MMC. The boot program must be a file named "boot.bin" written in the file system root directory. Its size must not exceed the maximum size allowed: 64 Kbytes (0x10000). The Arm exception vectors at offset 0 in the "boot.bin" file must also pass the test described in Arm Exception Vector Check.

19.1.4.13 Detailed Memory Boot Procedures

19.1.4.13.1 SD Card/e.MMC Boot

In the case of activated Card Detect pin in the Boot Configuration Packet, and if the level of the Card Detect pin is high, no communication with SD Card/e.MMC is performed (no IOs toggling). Otherwise, the SD Card/e.MMC access is initiated (IOs toggling).

Supported SD Card Devices

SD Card Boot supports all SD Card memories compliant with the SD Memory Card Specification V3.0. This includes SDMMC cards.

e.MMC with Boot Partition

The ROM code first checks if the e.MMC boot partition is enabled. If enabled, the ROM code reads the first 64 Kbytes of the boot partition and copy them into the internal SRAM.

FAT Filesystem Boot

If no boot partition is enabled on an e.MMC, the boot process continues with a standard SD Card/e.MMC detection, and the ROM code looks for a “boot.bin” file in the root directory of a FAT12/16/32 file system.

19.1.4.13.2 SPI Flash Boot

The ROM code allows booting from SPI memories connected to the QSPI controller. The QSPI_MODE bit must be set in the Boot Configuration Packet.

SPI Flash Boot supports only SPI Serial Flash devices.

The SPI Flash read is done by means of a Continuous Read command from the address 0x0. This command is 0x0B for Serial Flash devices.

Supported Serial Flash Devices

The SPI Flash Boot program supports all SPI Serial Flash devices responding correctly to the Get Status and Continuous Read commands.

19.1.4.13.3 QSPI NOR Flash Boot

Hardware Considerations

The ROM code configures the hardware so that:

- the QSPI controller uses SPI Mode 0 (CPOL = 0 and CPHA = 0),
- the QSPIx_SCK clock frequency is ≤ 50 MHz,
- QSPIx_SCK and QSPIx_CS do not use any internal pull-up/pull-down resistor,
- each QSPIx_IO{0,1,2,3} uses the PIO controller’s internal pull-up resistor.

Software Considerations

Before reading any data, the ROM code sends a software reset to the QSPI NOR memory. Then the ROM code looks for the Serial Flash Discoverable Parameters (SFDP) of the QSPI NOR memory, if available, to learn the parameters (instruction op code, timing settings) required to read the user-programmed boot file.

If SFDP tables are not available, the ROM code uses hard-coded values as fallback settings to read the boot file.

The ROM code supports any QSPI NOR memory which can provide its SFDP as defined in the JEDEC JESD216B standard.

The supported revisions of this JEDEC standard are:

- JESD216 (version 1.0)
- JESD216 rev. A (version 1.5)
- JESD216 rev. B (version 1.6)

Refer to the QSPI NOR memory data sheet to check compliance with the above JEDEC JESD216 standard revisions/versions.

QSPI NOR Memories with SFDP (JEDEC JESD216x Compliant)

The ROM code reads the memory SFDP tables to learn the factory settings (instruction op code, number of dummy cycles, etc.). The ROM code also reads bits[22:20] in DWORD15 from the Basic Flash Parameter table (refer to the JEDEC JESD216B specification) to select and then execute the relevant procedure, if any, to set the Quad Enable (QE) bit in some internal register of the QSPI NOR memory.

For most memory manufacturers, the QE bit is non-volatile and must be set before performing any Quad SPI command. This is the only persistent setting that the ROM code may change in the internal registers of the QSPI NOR memory. All other settings are kept unchanged.

Refer to the QSPI NOR memory data sheet to find which value was chosen by the memory manufacturer and written into the SFDP tables.

Finally, the ROM code reads the boot file from the data area of the QSPI NOR memory, and then continues its boot procedure.

QSPI NOR Memories without SFDP

This section only applies when the ROM code fails to read the SFDP tables from the QSPI NOR memory.

The ROM code reads the JEDEC ID of the QSPI NOR memory, and then selects the read settings based on the manufacturer ID (first byte of the JEDEC ID) from the following hard-coded values:

Table 19-2. QSPI NOR Memories Settings

	Cypress (01h)	Micron (20h)	Macronix (C2h)	Winbond (EFh)	Others
Fast Read protocol	SPI 1-4-4	SPI 1-4-4	SPI 1-4-4	SPI 1-4-4	SPI 1-1-1
Fast Read op code	EBh	EBh	EBh	EBh	0Bh
Address width	24 bits	24 bits	24 bits	24 bits	24 bits
Number of mode clock cycles	2	1	2	2	0
Number of wait states	4	9	4	4	8
Value of mode cycles to exit the 0-4-4 mode (normal read)	00h	1h	00h	FFh	N/A

Those hard-coded parameters give a last chance to the ROM code to boot from a QSPI NOR memory in either normal mode.

Table 19-3. QSPI NOR Memories Supported by ROM Code (Non Exhaustive)

Note: For an updated list of memories, refer to the application note “Booting from External Non-Volatile Memory (NVM) on SAMA7G5 MPUs” (document no. DS00004408) available on www.microchip.com.

19.1.4.14 Hardware and Software Constraints

The following table provides clock frequencies configured by the ROM code during boot.

Table 19-4. Clock Frequencies During External Memory Boot Sequence

Clock	Frequency
SYSPLL	378 MHz
CPU_CLK / CPUPLL	570 MHz
MCK0	142 MHz
MCK1	189 MHz
MCK4	378 MHz
SDMMC (init/operational)	400 kHz / 25 MHz
SPI	47 MHz
QSPI	47 MHz

The NVM drivers use several PIOs in Peripheral mode to communicate with external memory devices. Care must be taken when these PIOs are used by the application. The connected devices could be unintentionally driven at boot time, and thus electrical conflicts between the output pins used by the NVM drivers and the connected devices could occur.

The following table contains a list of pins that are driven during the boot program execution. These pins are driven during the boot sequence for a period of less than 1 second if no correct boot program is found. The drive strength of pull-up I/O pins is set to low while the pins are used in Peripheral mode by the ROM code.

Before performing the jump to the application in the internal SRAM, all the PIOs and peripherals used in the boot program are set to their reset state.

Table 19-5. PIO Driven During Boot Program Execution

NVM Bootloader	Peripheral	IO Set	Signal	PIO Line	Pull-up

19.1.5 Standard Monitor

This part of the ROM code is executed when no valid code is found in any external Flash memory during the NVM boot sequence, and if the MON_DIS field is not set to 1 in the Boot Configuration Packet.

The main RC oscillator is still used as the main clock.

To use the USB device interface, an external quartz or accurate clock must be connected to the chip.

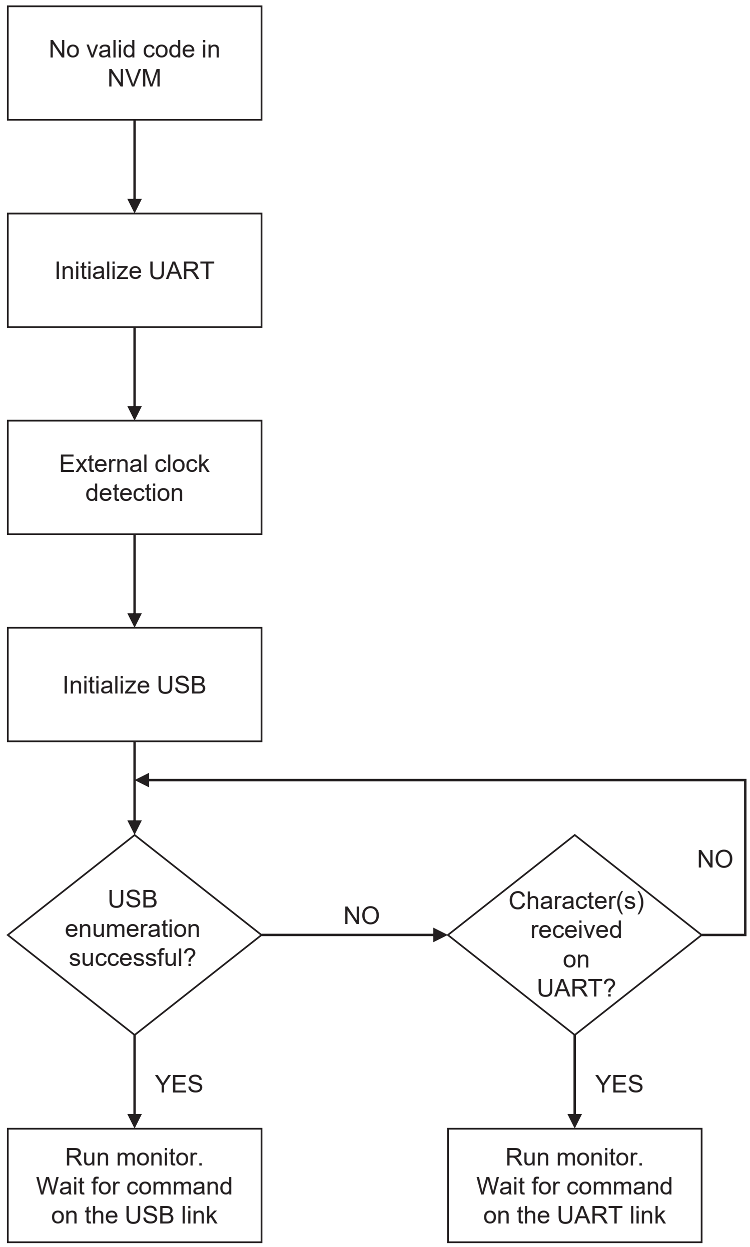
In case no external clock source is supplied, the USB interface is not activated and only a UART connection can be used as a monitor.

The monitor steps are:

- Initialize UART and USB.
- Check if USB device enumeration occurred.
- Check if characters are received on the UART.

Once the communication interface is identified, the monitor runs in an infinite loop waiting for different commands as listed in Command List.

Figure 19-8. Standard Monitor



19.1.5.1 Command List

Table 19-6. Commands Available Through Standard Monitor

Command	Action	Argument(s)	Example
N	Set Normal Mode	No argument	**N**#
T	Set Terminal Mode	No argument	**T**#
O	Write a byte	Address, Value#	**O**200001,CA#
o	Read a byte	Address,#	**o**200001,#

...........continued			
Command	**Action**	**Argument(s)**	**Example**
H	Write a halfword	Address, Value#	**H**200002,CAFE#
h	Read a halfword	Address,#	**h**200002,#
W	Write a word	Address, Value#	**W**200000,CAFEDECA#
w	Read a word	Address,#	**w**200000,#
S	Send a file	Address,#	**S**200000,#
R	Receive a file	Address, NbOfBytes#	**R**200000,1234#
G	Go	Address#	**G**200200#
V	Display version	No argument	**V**#

- Mode commands:
  - Normal mode configures monitor to send/receive data in binary format.
  - Terminal mode configures monitor to send/receive data in ASCII format.
- Write commands: Writes a byte (**O**), a halfword (**H**) or a word (**W**) to the target.
  - Address: address in hexadecimal
  - Value: byte, halfword or word to write in hexadecimal
  - Output: ‘>’
- Read commands: Reads a byte (**o**), a halfword (**h**) or a word (**w**) from the target.
  - Address: address in hexadecimal
  - Output: the byte, halfword or word read in hexadecimal followed by ‘>’
- Send a file (**S**): Sends a file to a specified address.
  - Address: address in hexadecimal
  - Output: ‘>’

    Note: There is a timeout on this command which is reached when the prompt ‘>’ appears before the end of the command execution.
- Receive a file (**R**): Receives data into a file from a specified address.
  - Address: address in hexadecimal
  - NbOfBytes: number of bytes in hexadecimal to receive
  - Output: ‘>’
- Go (**G**): Jumps to a specified address and executes the code.
  - Address: address to jump to in hexadecimal
  - Output: ‘>’ once returned from the program execution. If the executed program does not handle the link register at its entry and does not return, the prompt is not displayed.
- Get Version (**V**): Returns the Boot Program version.
  - Output: version, date and time of ROM code followed by ‘>’

19.1.5.2 DBGU/UART Console Port

Communication is performed through the DBGU/UART port initialized to 115,200 bauds: 8 bits of data, no parity, 1-stop bit.

19.1.5.2.1 Xmodem Protocol

The Send and Receive File commands use the Xmodem protocol to communicate. Any terminal using this protocol can be used to send the application file to the target. The size of the binary file to send must be lower than half the SRAM size because the Xmodem protocol requires some SRAM memory in order to work.

The Xmodem protocol supported is the 128-byte length block. This protocol uses a two-character CRC16 to ensure detection of maximum bit errors.

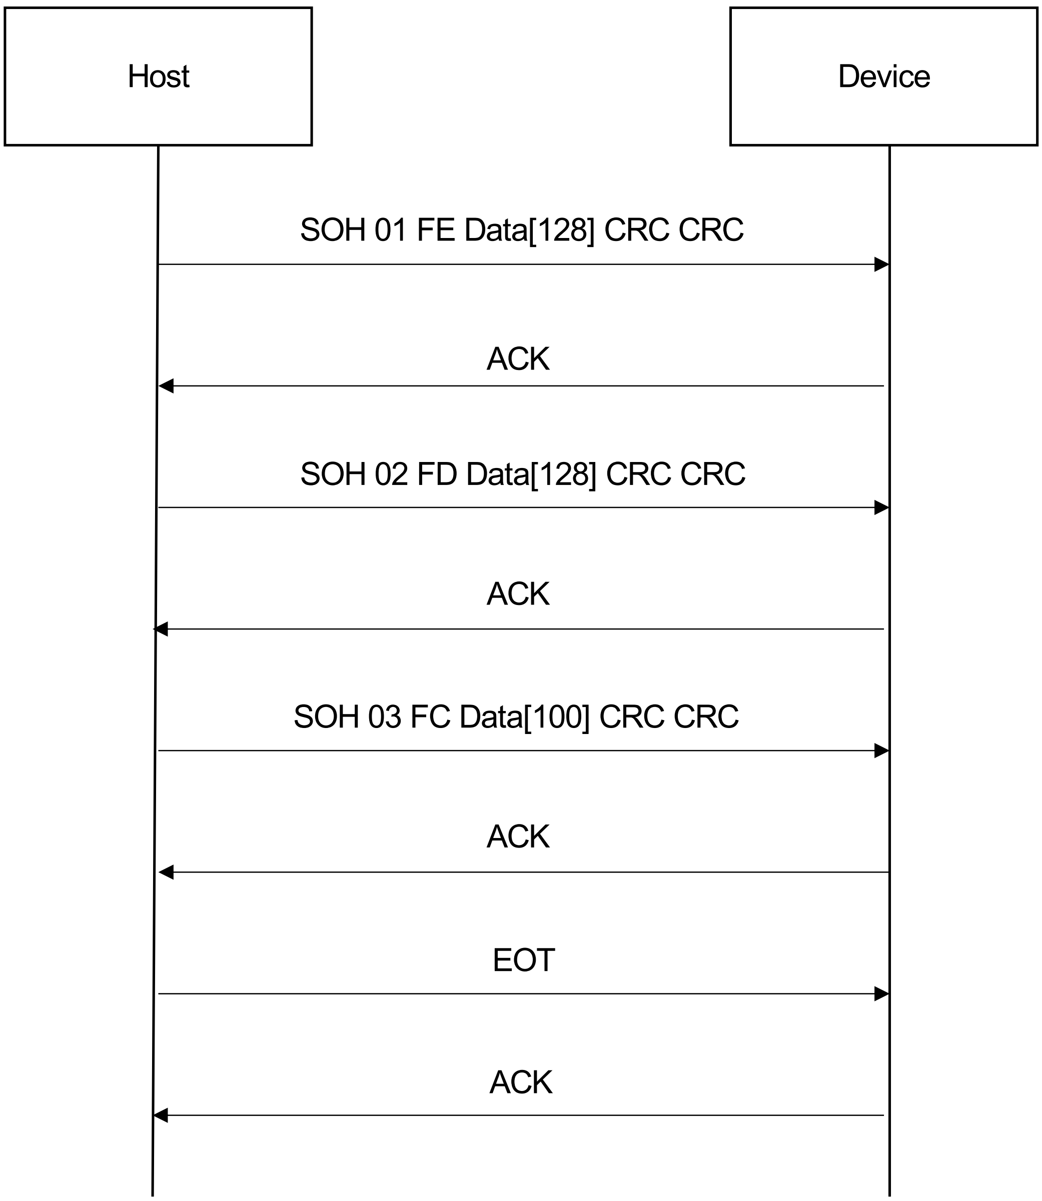
Xmodem protocol with CRC is supported by successful transmission reports provided both by a sender and by a receiver. Each transfer block is as follows:

<SOH><blk #><255-blk #><--128 data bytes--><checksum> in which:

- <SOH> = 01 hex
- <blk #> = binary number, starts at 01, increments by 1, and wraps 0FFH to 00H (not to 01)
- <255-blk #> = 1's complement of the blk#.
- <checksum> = 2-byte CRC16

The following figure shows a transmission using this protocol.

Figure 19-9. Xmodem Transfer Example



19.1.5.3 USB Device Port

19.1.5.3.1 Supported External Crystal/External Clocks

The SAMA7G5 chip supports an external crystal or external clock frequency at 16 MHz, 20 MHz, 24 MHz or 32 MHz to allow USB communication.

19.1.5.3.2 USB Class

The device uses the USB Communication Device Class (CDC) drivers to take advantage of the installed PC Serial Communication software to talk over the USB. The CDC is implemented in all releases of Microsoft Windows®, starting from Windows 98SE®. The CDC document, available at www.usb.org, describes how to implement devices such as ISDN modems and virtual COM ports.

The vendor ID is 0x03EB. The product ID is 0x6124. These references are used by the host operating system to mount the correct driver. On Windows systems, INF files contain the correspondence between vendor ID and product ID.

19.1.5.3.3 Enumeration Process

The USB protocol is a host/client protocol. The host starts the enumeration, sending requests to the device through the control endpoint. The device handles standard requests as defined in the USB specification.

Table 19-7. Handled Standard Requests

Request	Definition
GET_DESCRIPTOR	Returns the current device configuration value
SET_ADDRESS	Sets the device address for all future device accesses
SET_CONFIGURATION	Sets the device configuration
GET_CONFIGURATION	Returns the current device configuration value
GET_STATUS	Returns status for the specified recipient
SET_FEATURE	Used to set or enable a specific feature
CLEAR_FEATURE	Used to clear or disable a specific feature

The device also handles some class requests defined in the CDC class.

Table 19-8. Handled Class Requests

Request	Definition
SET_LINE_CODING	Configures DTE rate, stop bits, parity and number of character bits
GET_LINE_CODING	Requests current DTE rate, stop bits, parity and number of character bits
SET_CONTROL_LINE_STATE	RS-232 signal used to indicate to the DCE device that the DTE device is now present

Unhandled requests are stalled.

19.1.5.3.4 Communication Endpoints

Endpoint 0 is used for the enumeration process.

Endpoint 1 (64-byte Bulk OUT) and endpoint 2 (64-byte Bulk IN) are used as communication endpoints.

Monitor commands are sent by the host through Endpoint 1. If required, the message is split into several data payloads by the host driver.

If the command requires a response, the host sends IN transactions to pick up the response.

19.2 Secure Boot Strategies

19.2.1 Overview

The secure boot mode authenticates and deciphers a boot file stored in an external Non-Volatile Memory (NVM) prior to its execution. The boot file can be a bootstrap code or the user application. The secure boot ensures that only authorized code is executed, thus protecting the customer IP and providing a Root of Trust (RoT) in the hardware.

When the Secure Boot mode is enabled, the chip only allows booting on an authenticated and ciphered boot file. The boot file can be authenticated and deciphered in two ways:

- AES-CBC-CMAC mode:
  – Authentication is performed using the customer private CMAC key stored in the OTP memory, using the AES-CMAC algorithm.
  – Boot file decryption is performed using the customer private CBC key stored in the OTP memory, using the AES-CBC algorithm.
- AES-CBC-RSA mode:
  – Authentication is performed using the customer public key contained in the last X.509 certificate chain stored after the boot file.
  – Boot file decryption is performed using the customer private key stored in the OTP memory, using the AES-CBC algorithm.

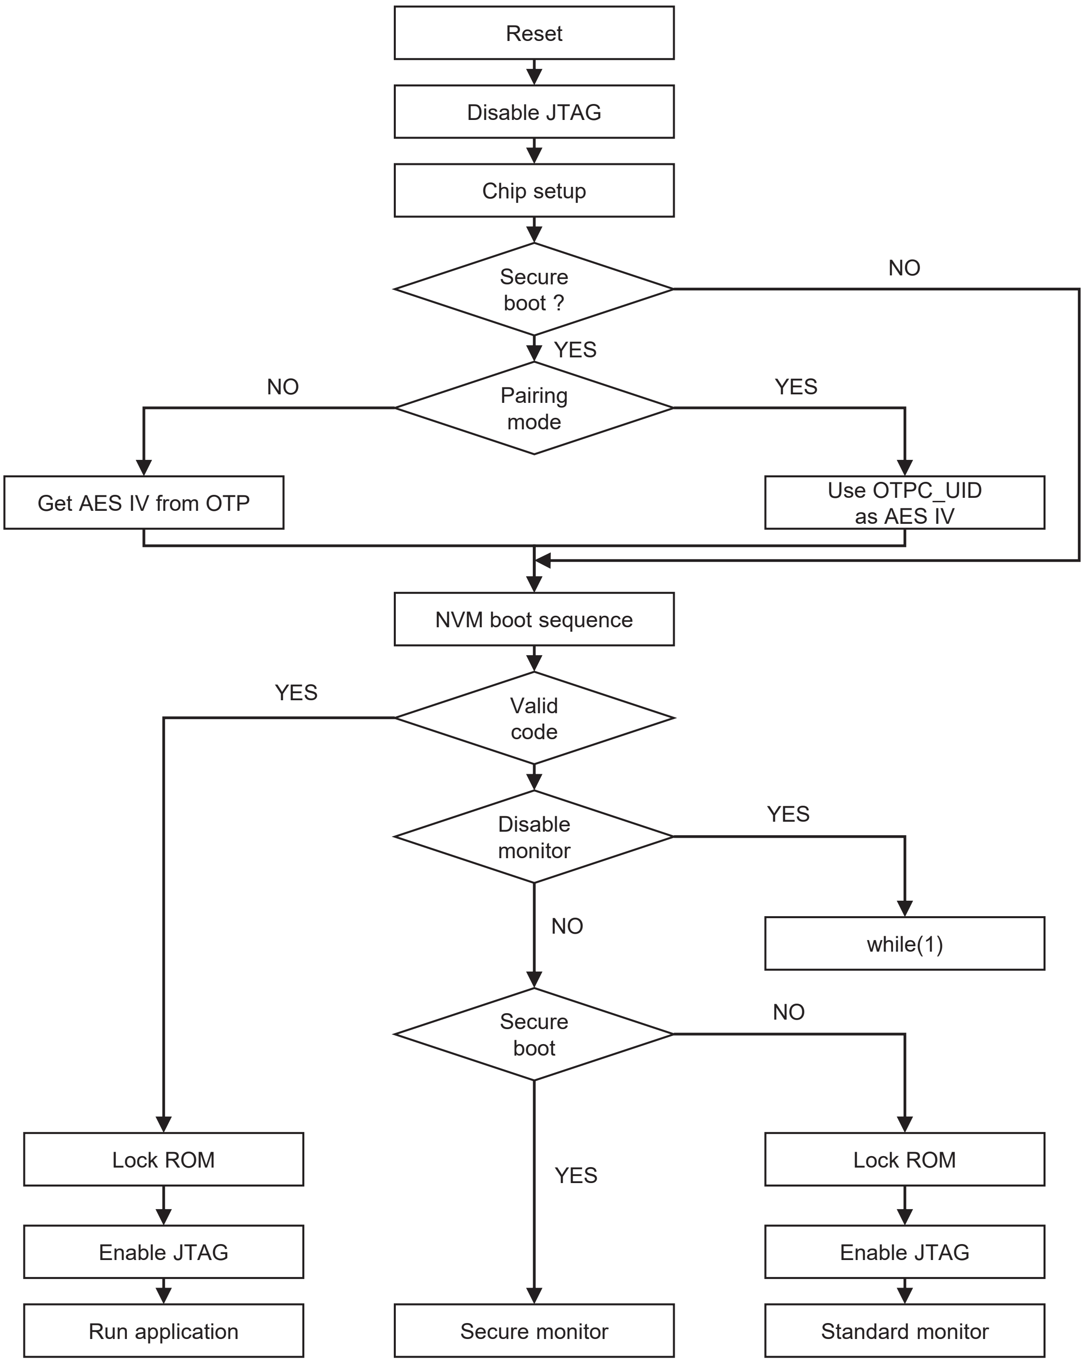
Additionally, a 'pairing' mode can be enabled. In this case, the customer private CBC key is diversified with the Chip Unique ID to decipher the boot file.

Encryption is supported by an AES (using HW acceleration); in addition, either symmetric (AES-CMAC) or asymmetric (RSA-based using X509 certificate chain) authentication is supported.

19.2.2 Flow Diagram

The standard and secure boot sequence flow is detailed in the following figure.

Figure 19-10. Boot Sequence Flow



19.2.3 Secure Boot Configuration

In addition to the Boot Configuration Packet content, the boot sequence flow is also controlled with the data stored in the Secure Boot Configuration packet.

The Secure Boot Configuration is stored in the Secure Boot Configuration Packet in the OTP user area. It defines all the information required to boot in Secure mode:

- Activate Secure mode
- Authentication mode
- Pairing mode option
- Number of keys
- etc.

See Secure Boot Configuration User Interface for a detailed description of the fields in the Secure Boot Configuration Packet.

During the prototyping phase, the content of the Boot Configuration and Secure Boot Configuration Packets can be overridden using the OTPC Emulation mode. See Boot Configuration Packet for more information.

19.2.4 Secure Boot Configuration User Interface

Table 19-9. Secure Boot Configuration Packet

Offset	Name	Description
0x00	SEC_MODE_EN	Secure mode enabled
0x04	AUTH_MODE	Authentication mode selection
0x08	PAIRING_MODE_EN	Pairing mode enabled
0x0C	KEY_WRITTEN	Key written
0x10	IV	AES Initialization Vector address
0x14	RSA_HASH	RSA Root Certificate public key hash address
0x18	CBC_KEY	AES CBC key
0x1C	CMAC_KEY	AES CMAC key

19.2.4.1 Secure Boot Mode Enable

Name: SEC_BOOT_MODE_EN

Bit	31	30	29	28	27	26	25	24
	SECURE_BOOT_MODE_ENABLE							
Bit	**23**	**22**	**21**	**20**	**19**	**18**	**17**	**16**
	SECURE_BOOT_MODE_ENABLE							
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**
	SECURE_BOOT_MODE_ENABLE							
Bit	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	SECURE_BOOT_MODE_ENABLE							

SECURE_BOOT_MODE_ENABLE

0: Secure Boot mode is disabled.

1: Secure Boot mode is enabled.

19.2.4.2 Authentication Mode

Name: AUTH_MODE

Bit	31	30	29	28	27	26	25	24
	AUTHENTICATION_MODE							
Bit	**23**	**22**	**21**	**20**	**19**	**18**	**17**	**16**
	AUTHENTICATION_MODE							
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**
	AUTHENTICATION_MODE							
Bit	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	AUTHENTICATION_MODE							

AUTHENTICATION_MODE

0: AES-CMAC is used for authentication.

1: RSA signature verification is used for authentication.

19.2.4.3 Pairing Mode Enable

Name: PAIRING_MODE_EN

Bit	31	30	29	28	27	26	25	24
	PAIRING_MODE_ENABLE							
Bit	**23**	**22**	**21**	**20**	**19**	**18**	**17**	**16**
	PAIRING_MODE_ENABLE							
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**
	PAIRING_MODE_ENABLE							
Bit	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	PAIRING_MODE_ENABLE							

PAIRING_MODE_ENABLE

0: Pairing mode is disabled.

Different from 0: Pairing mode is enabled.

19.2.4.4 Key Written

Name: KEY_WRITTEN

Bit	31	30	29	28	27	26	25	24
	KEY_WRITTEN							
Bit	**23**	**22**	**21**	**20**	**19**	**18**	**17**	**16**
	KEY_WRITTEN							
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**
	KEY_WRITTEN							
Bit	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	KEY_WRITTEN							

KEY_WRITTEN

0: Customer secret keys are not written in the OTP memory.

Different from 0: Customer secret keys are written in the OTP memory.

19.2.4.5 Initialization Vector Address

Name: IV

Bit	31	30	29	28	27	26	25	24
	IV_ADDRESS							
Bit	23	22	21	20	19	18	17	16
	IV_ADDRESS							
Bit	15	14	13	12	11	10	9	8
	IV_ADDRESS							
Bit	7	6	5	4	3	2	1	0
	IV_ADDRESS							

IV_ADDRESS: Address of the OTP packet containing the AES Initialization Vector

19.2.4.6 RSA Public Key Hash Address

Name: RSA_HASH

Bit	31	30	29	28	27	26	25	24
	RSA_HASH_ADDRESS							
Bit	**23**	**22**	**21**	**20**	**19**	**18**	**17**	**16**
	RSA_HASH_ADDRESS							
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**
	RSA_HASH_ADDRESS							
Bit	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	RSA_HASH_ADDRESS							

RSA_HASH_ADDRESS: Address of the OTP packet containing the hash of the root certificate CA

19.2.4.7 AES-CBC Key Address

Name: CBC_KEY

Bit	31	30	29	28	27	26	25	24
	AES_CBC_KEY_ADDRESS							
Bit	23	22	21	20	19	18	17	16
	AES_CBC_KEY_ADDRESS							
Bit	15	14	13	12	11	10	9	8
	AES_CBC_KEY_ADDRESS							
Bit	7	6	5	4	3	2	1	0
	AES_CBC_KEY_ADDRESS							

AES_CBC_KEY_ADDRESS: Address of the OTP packet containing the secret key for AES-CBC

19.2.4.8 AES-CMAC Key Address Register

Name: CMAC_KEY

Bit	31	30	29	28	27	26	25	24
	AES_CMAC_KEY_ADDRESS							
Bit	23	22	21	20	19	18	17	16
	AES_CMAC_KEY_ADDRESS							
Bit	15	14	13	12	11	10	9	8
	AES_CMAC_KEY_ADDRESS							
Bit	7	6	5	4	3	2	1	0
	AES_CMAC_KEY_ADDRESS							

AES_CMAC_KEY_ADDRESS: Address of the OTP packet containing the secret key for AES-CMAC

19.2.5 Secure Valid Code Detection

The valid code detection in Secure mode is similar to the one in Standard Boot mode. However, additional checks and operations are done.

If the initialization of NVM is successful, the ROM code reads and deciphers the first 32 bytes of the potential secure boot file to find a valid Arm exception vector table (see Arm Exception Vector Check). From the sixth vector, the ROM code extracts the size of the boot file including its signature. When the AUTH_MODE field is set to 1 in the Secure Boot Configuration Packet, the size of the X.509 certificate chain is also extracted. The boot file size must be 16 bytes aligned (AES block size). The sum of the boot file and certificate sizes must be lower than 64 Kbytes. If these first validations fail, the ROM code restores the memory interface PIO and settings to their reset values and then tries to boot on the next NVM.

Otherwise, the total size is used to copy the boot file, its signature and the X.509 certificate chain from the NVM into the internal SRAM.

Next, depending on the AUTH_MODE field in the Secure Boot Configuration Packet, either the AES-CMAC digest or the RSA signature of the boot file is checked. As usual, if this final validation fails, the peripheral is reset and the ROM code jumps to the next NVM.

If the boot file verification passes, the ROM code deciphers the boot file stored in the internal SRAM.

Since the NVM interface is no longer needed, the ROM code restores the interface registers and IO reset values.

Finally, the ROM code locks access to ROM area, enables JTAG and then branches to 0x00100000 to execute the boot file.

19.2.5.1 6th Vector Format

When the AUTH_MODE field is cleared in the Secure Boot Configuration Packet, the sixth entry of the Arm exception vector table stores the size of the boot file in bytes, including the 16 bytes of its AES-CMAC signature.

When the AUTH_MODE field is set to 1 in the Boot Configuration word, the sixth entry of the Arm exception vector table stores both the size of the boot file including its RSA signature and the size of the X.509 certificate chain. The size of the RSA signature is also encoded.

Bit	31	30	29	28	27	26	25	24
	CERTIFICATE_SIZE							
Bit	**23**	**22**	**21**	**20**	**19**	**18**	**17**	**16**
	CERTIFICATE_SIZE					SIG_CODE		BT_SIZE
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**
	BT_SIZE							
Bit	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	BT_SIZE							

BT_SIZE: Boot file size, in bytes

SIG_CODE: Code for the RSA signature length

00: 2048 bits

01: 3072 bits

10: 4096 bits

11: RFU

CERTIFICATE_SIZE: Size of the of X.509 certificate chain, in bytes

19.2.5.2 e.MMC/SD Card File System

In Secure Boot mode, the ROM code looks for a `boot.cip` file in the root directory of a FAT12/16/32 file system. The secure boot file, its signature and the chain of X.509 certificates are stored in the `boot.cip` file.

19.2.6 Encryption, Decryption and Authentication

For security reasons, the customer's two 256-bit secret keys are transferred only through the Host Key Bus from the OTPC key packet to the AES hardware. The customer's AES Initialization Vector read from the OTP User area and the first key are used by the AES-CBC algorithm, whereas the second is dedicated to the AES-CMAC computation.

Encryption and decryption are processed using the NIST recommended AES CBC mode defined in NIST Special Publication 800-38A [NIST_MODE_OP].

When selected, the Message Authentication Code is processed using the NIST recommended CMAC. The CMAC used as a Message Authentication Code (MAC) is the CMAC based on the AES. The AES-CMAC outputs a 128-bit digest.

Otherwise, the authentication is secured by an RSA signature. The public key cryptographic implementation then relies on X.509 certificates. These certificates are chained and stored right after the boot file and its signature in the NVM.

The first certificate in the chain (at the lowest address in memory) is called the "root certificate". The modulus and the exponent are extracted from the public key stored in the root certificate. A SHA-256 digest is computed on the concatenation of the modulus and the exponent. This 256-bit digest is compared to the "RSA Hash" to validate the root certificate.

Then, except for the root certificate, every certificate is signed by the private key associated with the previous certificate in the chain. So, its previous certificate is used to validate a certificate in a recursive process.

Finally, the boot file is signed with the private key associated with the last certificate. So, the last certificate is used to validate the boot file signature.

19.2.7 Secure Boot Mode Configuration

By default, the device operates a Standard Boot sequence (see Standard Boot Strategies). In this mode, the chip can boot on a standard binary program present in any external non-volatile memory.

To configure the device to operate a Secure Boot sequence and to be able to boot a ciphered application, at least two steps must be followed, the third being done only when using the RSA signature:

1. Set the chip in Secure mode.
2. Send the customer key.
3. (If AES-RSA mode is selected) Send RSA Hash.

These steps are mandatory prior to programming a boot file in an external NVM and can only be done once.

To set the chip in Secure mode, a valid Secure Boot Configuration packet must be written.

19.2.8 Programming a Boot File

If the boot file is ciphered with an incorrect key or has an incorrect signature, the Secure Boot sequence will not detect this boot file as valid.

The boot file cipher process can be done by the Secure SAM-BA cipher tool.

19.2.9 Secure Monitor

When no bootable program is found in any external NVM memory during the boot sequence and Secure mode is enabled, the ROM code executes the secure monitor.

The communication link is a USB connection in CDC mode (seen as a serial COM port on the OS).

The set of commands implemented in the secure monitor enables the user to send all the commands to program the customer key and the HASH of the public RSA key and to configure the Secure Boot mode.

19.2.9.1 Generic Commands

The command format is similar to the standard monitor command format, and is composed of command opcode and arguments, and ends with a '#' character. Depending on the command, a data payload can be added after the command. In this case, the payload must be sent after the secure monitor has acknowledged the command and instructed how the data payload must be split (size of the payload).

19.2.9.2 Command Format

The commands are formatted as follows:

____,________,________,________,__#

`opcode addrxx length not_used rw`

where:

- `opcode`—4 characters of the command.
- `addr`—the address field is max 8 characters long, and contains the hexadecimal address value without '0x'.
- `length`—in case of a write command, this field indicates the size of the data to be sent, in hexadecimal, without '0x'.
- `not_used`—this field is not used for the moment.
- `rw`—indicates a read or write operation (00 for read, 01 for write).

Table 19-10. Simple Commands

Command	Full Name	Description
SEMB	SET_EXT_MEM_BOOT_EN	Set external memory boot enable
SKIF	SET_KEYS_IN_FUSE	Set keys in fuse
SPAI	SET_PAIRING_MODE	Set Pairing mode
SMDI	SET_MONITOR_DIS	Set monitor disable
SBSD	SET_BSCR_DIS	Set BSCR disable
SSBD	SET_SEC_DBG	Set secure debug
SJTD	SET_JTAG_DIS	Set JTAG disable fuse bit
CRST(1)	CHIP_RESET	Reset the chip

Note:

1. USB communication is cut when this command is executed by the chip.

Table 19-11. Read Version Command

Command	Full Name	Description
RVER	READ_ROM_VERSION	Read ROM code version

Table 19-12. Key Management Commands

Command	Full Name	Description
WCKY	WRITE_CUSTOMER_KEY	Send customer keys and initialization vector (640 bits)
WRHA	WRITE_RSA_HASH	Send RSA hash of root certificate public key

Note: Sending the commands in the table above automatically configures the corresponding values in the SIGN_MODE and EXPAND_MODE fields of the Boot Configuration Word.

Table 19-13. Applet Related Commands

Command	Full Name	Description
SAPT	SEND_APPLET	Send memory programming applet
SMBX	SEND_APPLET_MAILBOX	Send applet mailbox content

...........continued		
Command	**Full Name**	**Description**
RMBX	READ_APPLET_MAILBOX	Read applet mailbox content
EAPP	APPLET_EXECUTE	Execute apple
SFIL	SEND_FILE	Send file (to be programmed into an external memory)
RFIL	READ_FILE	Read file from an external memory

19.2.9.3 Monitor Answer

The Secure SAM-BA monitor answers any command with an acknowledge message formatted as follows:

____,________,________#[<`payload`>]

`opcode errcode length`

where:

- `opcode`—4 characters of the command
- `errcode`—value of the error code
- `length`—in cases where the monitor must send data to SAM-BA, this field shows how much data is in the payload, thus how much data SAM-BA has to read.
- `payload`—optional data, depends on the command.

Table 19-14. Command List

Command	Full Name	Description
CACK	SEND_CMD_ACK	Return the status of simple commands
ASTA	SEND_APPLET_STATUS	Return the status after execution of an applet
SVER	SEND_ROM_VERSION	Return ROM Code version

Table 19-15. Error Code

Error name	Hex value	Description
secCmdOK	0x000000000	Command OK
secCmdTooLong	0xFFFFFFFF	Whole command size too long
secCmdOpcodeSizeErr	0xFFFFFFFE	Opcode size too long
secCmdAddrSizeErr	0xFFFFFFFD	Address field size too long
secCmdLenSizeErr	0xFFFFFFFC	Length field size too long
secCmdRWSizeErr	0xFFFFFFFA	RW field size too long
secCmdOpcodeUnknown	0xFFFFFFF9	Unknown command op-code
secCmdCustKeyLengthErr	0xFFFFFFF8	Customer key payload message size error
secCmdCustKeyNotWritten	0xFFFFFFF7	Customer key has not been written
secCmdCustKeyAlreadyWritten	0xFFFFFFF6	A customer key has already been written in fuses
secCmdCmacErr	0xFFFFFFF5	Message CMAC error
secCmdDecryptErr	0xFFFFFFF4	Error during message decryption
secCmdKeyDerivErr	0xFFFFFFF3	Error during key derivation
secCmdRsaHashAlreadyWritten	0xFFFFFFEE	An RSA hash has already been written in fuses
secCmdFuseWriteErr	0xFFFFFFED	Error while writing a fuse bit

...........continued

Error name	Hex value	Description
secCmdExpandModeAlreadyWritten	0xFFFFFFEC	Field EXPAND_MODE in the Boot Configuration word has already been programmed

19.2.9.4 Command Description

19.2.9.4.1 Read ROM Code Version

For this specific command, the Secure SAM-BA monitor replies with the SVER opcode, and indicates that the ROM code version string length is 30 bytes, so the external tool knows how many character should be received.

(PC to device) `>> RVER,0,0,0,00#`

(Device to PC) `<< SVER,00000000,00000030#v1.0...........Jul 26 2019.....011:14:22.......`

19.2.9.4.2 Write Customer Key

Sending the customer key to the chip involves sending a binary payload (the ciphered message containing the customer key). This payload must be sent by the tool after receiving the acknowledge from the monitor, showing how many bytes are expected.

(PC to device) `>> WCKY,0,70,0,01#`

(Device to PC) `<< CACK,00000000,00000070#`

(PC to device) `>> <key_file.cip>`

(Device to PC) `<< CACK,00000000,00000000#`

19.2.9.4.3 Programming External Memories

Programming external memories requires the use of applets, which are memory programming algorithms running in the target internal SRAM.

Applets permit ROM code size reduction, no hard-coded memory identification tables, and give the possibility to add support for several types of external memories.

Applet binaries are ciphered and bundled into the Secure SAM-BA tool. They cannot be modified by the user and only Microchip can provide them.

Depending on the memory and applet implementation, the number of commands available can differ from one applet to another.

The first thing to do is to send the ciphered applet to the target. This is done through the Send Applet command:

(Device to PC) `>> SAPT,0,9870,0,01#`

(Device to PC) `<< CACK,00000000,00009870#`

(PC to device) `>> <applet_binary.cip>`

(Device to PC) `<< CACK,00000000,00000000#`

In the example above, Secure SAM-BA requests sending an applet of size 0x9870 and the monitor acknowledges this. Secure SAM-BA sends the applet ciphered binary file (applet_binary.cip), and after checking the signature and deciphering the applet in SRAM, the monitor sends the status (0x0: successful).

Now that the applet is in SRAM, before executing its code, its mailbox must be filled. The mailbox is the 32-word buffer, at the beginning of the applet area, which allows exchanging commands and arguments with the applet.

To do so, the Send Applet Mailbox command must be issued.

The mailbox is not ciphered, and is automatically written at the correct address by the ROM code.

(PC to device) `>> SMBX,0,80,0,01#`

(Device to PC) `<< CACK,00000000,00000080#`

(PC to device) `>> <applet_init_mailbox.bin>`

(Device to PC) `<< CACK,00000000,00000000#`

Now the applet program can be run with the Execute Applet command:

(PC to device) `>> EAPP,0,0,0,00#`

(Device to PC) `<< ASTA,00000000,00000000#`

The monitor replies with a status of the applet execution (0x0: successful).

During this step, the ROM code has retrieved the information that will be used when receiving the next Write File command:

- A memory has been successfully detected/initialized
- The address and the size of the data buffer: where the data exchanged can be stored (the final binary to be programmed into the external memory can be bigger than the buffer size)

Now a Send File command can be issued, with the size:

(PC to device) `>> SFIL,0,5000,0,01#`

(Device to PC) `<< CACK,00000000,00004000#`

(PC to device) `>> <first 0x4000 bytes of the file to be programmed>`

(Device to PC) `<< CACK,00000000,00001000#`

(PC to device) `>> <next file chunk of 0x1000 bytes>`

(Device to PC) `<< CACK,00000000,00000000#`

19.3 Key Provisioning and Bootstrap Programming

This section provides some recommendations to ensure a good security level when configuring and using Secure Boot mode.

19.3.1 Configuring Secure Boot Mode

The recommended procedure to configure the Secure Boot mode, using the SAM-BA tool (available on www.microchip.com), is the following:

1. Write the Boot Configuration Packet, with the required boot settings and boot memory interface.
2. Set the Secure Boot mode.
3. Send the customer key.
4. Send the Root Certificate Hash (in case RSA signature is used).
5. Configure the boot memory interface.
6. Program the ciphered bootstrap.
7. Program the other application files.
8. **Disable the monitor to avoid any further access to the Secure monitor.**
9. **Lock the Boot Configuration Packet.**

Note: Keeping the Secure Monitor enabled in order to update the bootstrap on the field or in-house is not recommended.

⚠WARNING The Boot Configuration Packet must be written as the very first packet in OTP.

19.3.2 Bootstrap Development and Updates

This section provides information about the bootstrap and how to update the ciphered bootstrap on a system already provisioned and having the secure monitor disabled.

In order to protect the CBC ciphered bootstrap from known plain text attacks, it is strongly recommended to follow several common rules:

- Avoid compiling and linking “as is” source code that is publicly available.
- Apply secure software development basic principles (add custom parts, add random data, change objects order, etc.).
- Keep bootstrap sources (binary and ciphered versions) in safe places.
- Keep bootstrap as small and robust as possible to reduce number of updates.

19.3.2.1 Bootstrap Ciphering

Before update, the bootstrap must be ciphered in accordance with the Secure Boot mode selected.

When the Pairing mode is used, the bootstrap authentication code and ciphering differ for each device, because it is paired using the device unique ID. Remote update in the field is possible if the system can connect to a server. The system sends its chip ID to the server, and the server computes the new bootstrap that is sent back to the system.

In this case, it is highly recommended to not try any field update in this mode.

For other Secure Boot modes, the bootstrap can be prepared using the Secure SAM-BA cipher tool, and then deployed for an update on all devices.

Securing *.CIP files

Microchip’s Secure SAM-BA Cipher utility outputs encrypted *.CIP files for use in provisioning at final manufacturing. As these files contain both customer keys and firmware, the *.CIP files must be securely stored with restricted and controlled access.

19.3.2.2 Bootstrap Field Update

19.3.2.2.1 Case 1: SAM-BA Monitor is disabled (the “MON_DIS” word is filled in the Boot Configuration Packet)

In this case, the bootstrap itself or the customer application must be in charge to update the bootstrap, by writing the new bootstrap in the boot memory in replacement of the existing one.

To do that, the program in charge to do the update must be able to:

- retrieve the new ciphered bootstrap,
- erase the existing one,
- program the new one.

Important: The last two operations must not be interrupted, otherwise the boot process could be broken.

19.3.2.2.2 Case 2: Secure SAM-BA Monitor is still available (the “MON_DIS” word is zeroed in the Boot Configuration Packet - not recommended for systems in production)

1. Disable the access to the external boot memory (Chip Select pin, Card Detect Pin, etc., depending on the chosen boot memory) to prevent its access by the ROM code on the next reboot.
2. Connect a USB cable on the USB device port, or on the UART used as SAM-BA Monitor console terminal.
3. Reset the chip.
4. Enable the access to the external boot memory.
5. Program the bootstrap using the SAM-BA tool.
6. Lock the Boot Configuration Packet.

19.3.3 Monitor Disabling by the Bootstrap

It is highly recommended to fill this word and lock the Boot Configuration Packet at the production stage, but if none of those conditions are met, writing the “MON_DIS” word can be performed by the bootstrap or by the customer application.

To write the “MON_DIS” word and lock it, an update of the Boot Configuration Packet in the OTP memory is required. In the section OTP Memory Controller (OTPC), refer to:

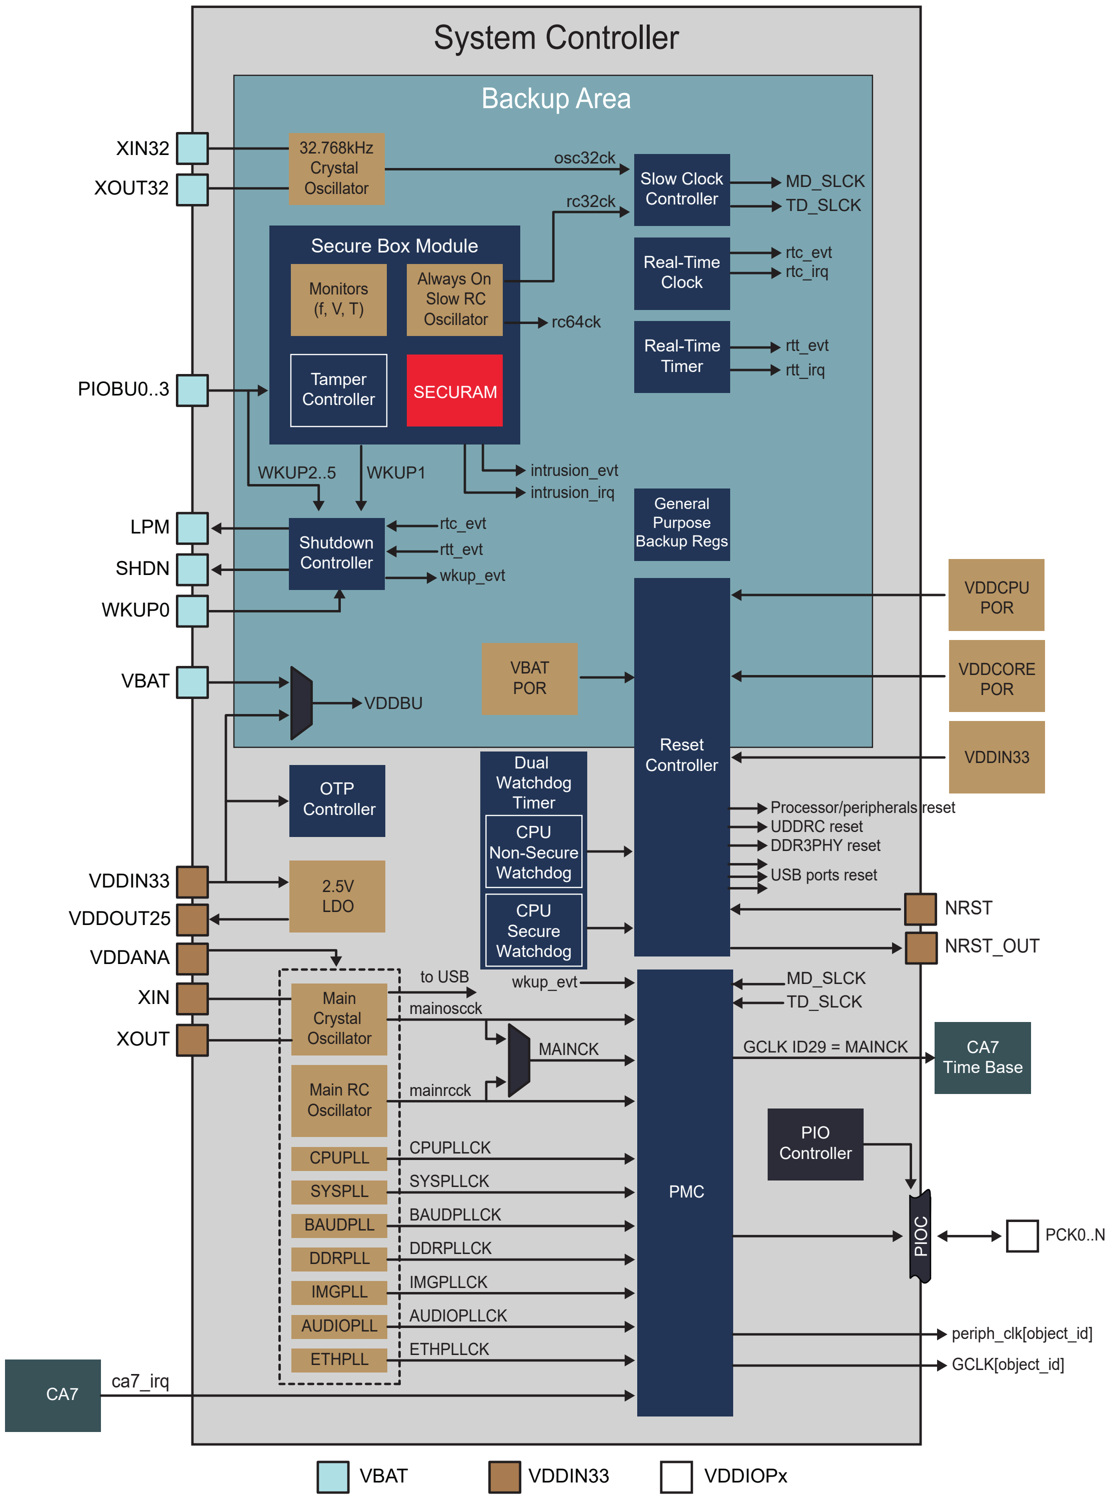
- Updating an Existing Packet from the User Interface

- Locking a Packet

20. SYSTEM CONTROLLER SUBSYSTEM

20.1 Block Diagram

Figure 20-1. System Controller Block Diagram



20.2 Components

- Peripherals powered by VDDBU (either VBAT or VDDIN33):
  - System Controller Write Protection (SYSCWP)
  - General Purpose Backup Registers (GPBR)
  - Reset Controller (RSTC)
  - Real-time Timer (RTT)
  - Real-time Clock (RTC)
  - Shutdown Controller (SHDWC)
  - Slow Clock Controller (SCKC)
  - Special Function Registers Backup (SFRBU)
  - Security Module (SECUMOD)
- Peripherals powered by VDDCORE:
  - Dual Watchdog Timer (DWDT)
  - Chip Identifier (CHIPID)
  - OTP Memory Controller (OTPC)
  - Special Function Registers (SFR)
  - Clock Generator and Power Management Controller (PMC)
  - Parallel Input/Output Controller (PIO)
  - 64-bit Periodic Interval Timer (PIT64B)

20.3 Product Dependencies

20.3.1 Clocks

All system controller peripherals, except the 6x PIT64B instances, are part of the CPU System and Security (CSS) matrix that runs on MCK0.

Note: The MCK0 frequency is directly related to the CPU clock, so any change on the CPU clock impacts MCK0.

The system controller peripherals are always on, except:

- Parallel Input/Output Controllers (PIOs) that have one clock control (PIOA) for all PIO controllers, clocked with MCK0
- Special Function Registers (SFR)

PIT64B0 to PIT64B5 are located on the APB Client (APS) matrix, clocked with MCK1.

In addition, PIT64B0 to PIT64B5 feature a GCLK input for flexibility. CA7 Base Time (GCLK ID29), defined as MAINCK, is automatically started at reset.

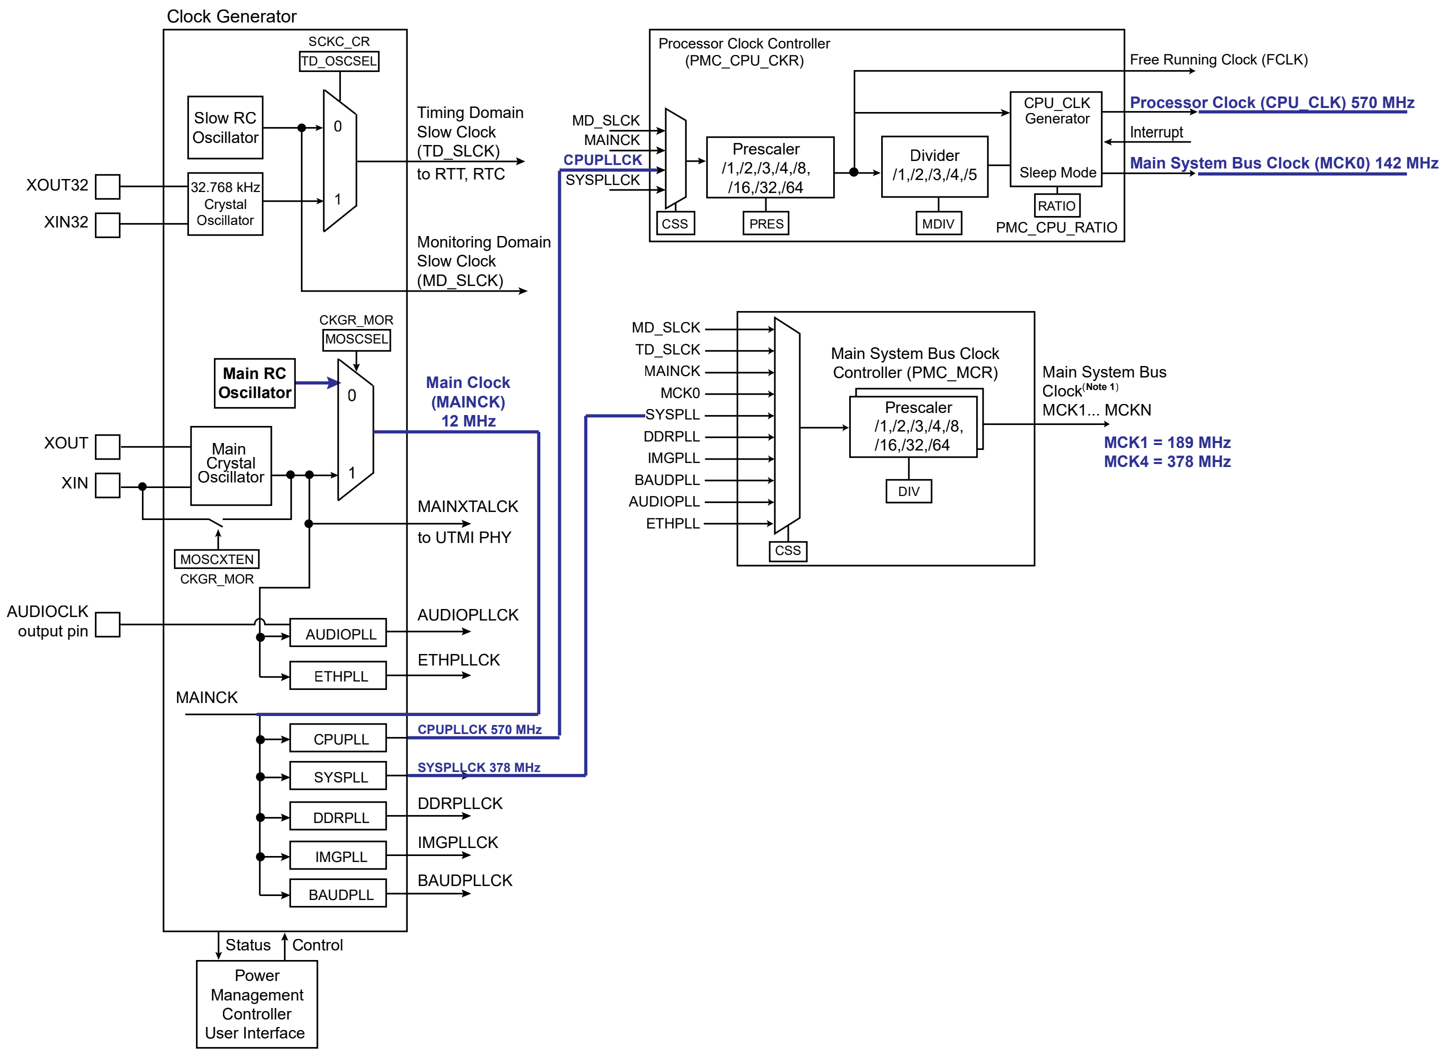
20.3.1.1 Changing System Frequencies

After ROM code execution, the system clock is set as follows:

- MAINCK is fed by the main RC oscillator i.e., 12 MHz.
- CPUPLL is set to 570 MHz.
- MCK0 is set to CPUPLL/4 i.e., 142 MHz.
- SYSPLL is set to 378 MHz.
- MCK1 is set to SYSPLL/2 i.e., 189 MHz.
- MCK4 is set to SYSPLL i.e., 378 MHz.

This is illustrated in the following figure.

Figure 20-2. PMC Rom Code Configuration



To avoid any overclocking during system clock modification, it is recommended to change system frequencies in two steps.

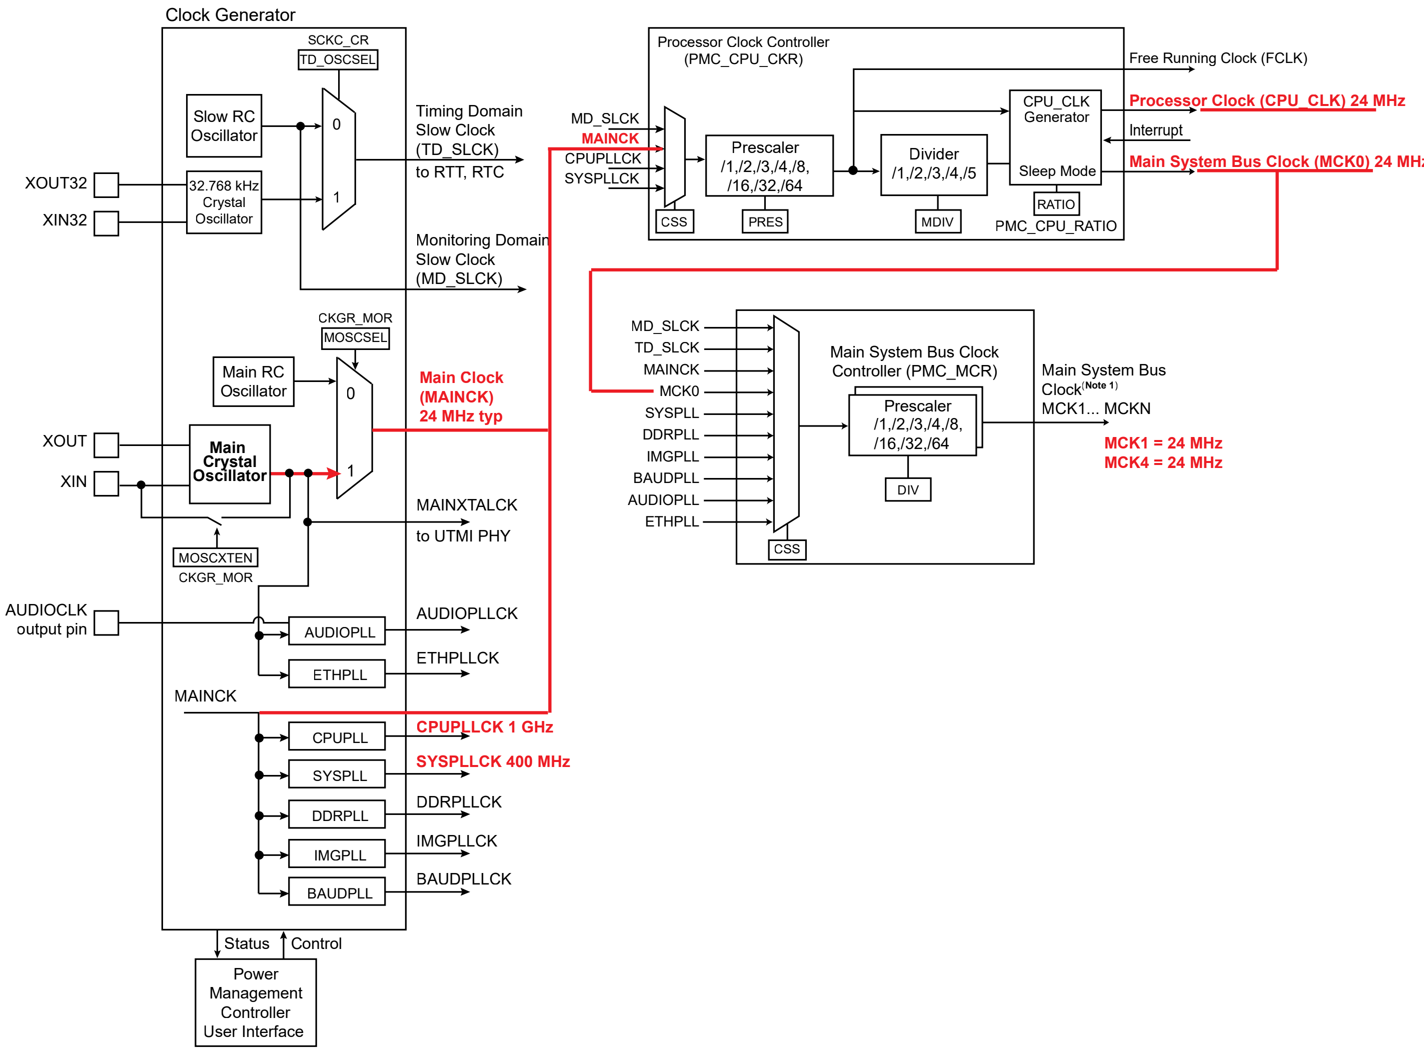
The first step leads to a known and basic intermediate state where all clocks are in a low-frequency range.

For example, the following sequence can be performed:

1. Set MCK0 to MAINCK, i.e., 12 MHz.
2. Set MCK1 to MCK0 i.e., 12 MHz.
3. Set MCK4 to MCK0 i.e., 12 MHz.
4. Set MAINCK to Crystal Oscillator, typically 24 MHz. MCK0, MCK1 and MCK4 then run at 24 MHz.
5. Set CPUPLL to 1 GHz.
6. Set SYSPLL to 400 MHz.

This intermediate state is illustrated in the following figure.

Figure 20-3. PMC Intermediate Configuration



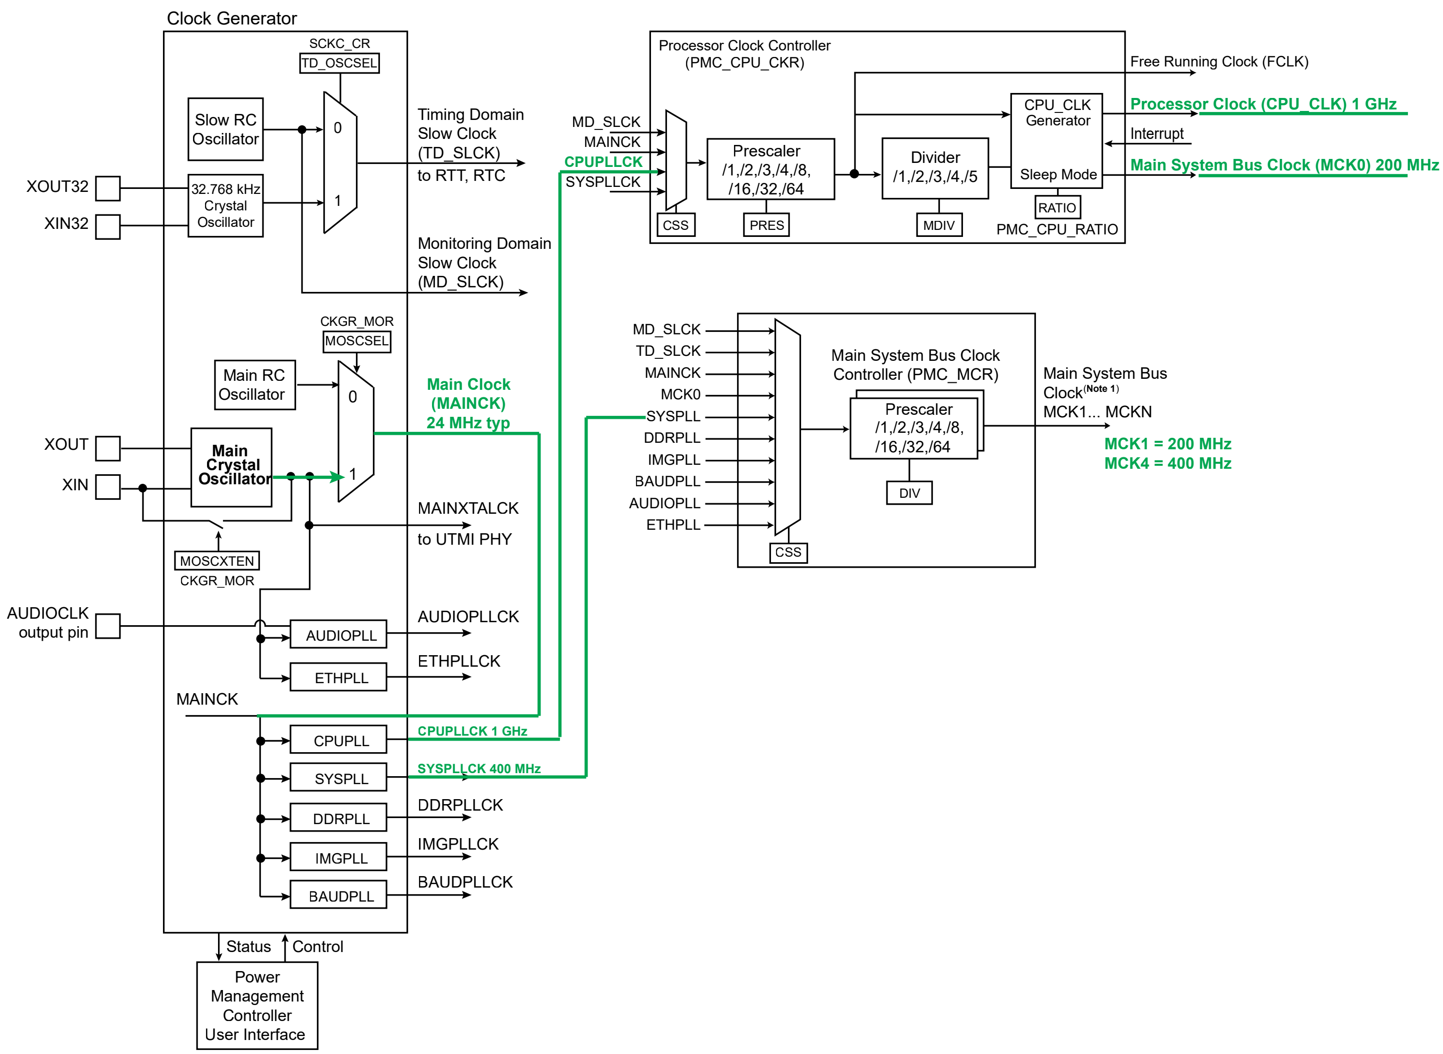
The second step leads to the final expected state.

Perform the following sequence:

1. Set MCK0 to CPUPLL/5 i.e., 200 MHz.
2. Set MCK1 to SYSPLL/2 i.e., 200 MHz.
3. Set MCK4 to SYSPLL i.e., 400 MHz.

The final state is illustrated in the following figure.

Figure 20-4. PMC Final Configuration



20.3.2 Interrupts

Each peripheral has its own GIC interrupt ID, except CHIP_ID, SFRBU, SYSCWP and GPBR, that have no interrupt line.

DWDT has two separated interrupts: one programmable secure and one never secure.

20.3.3 Reset

System controller peripherals are connected to the processor and peripherals reset line.

20.3.4 I/Os

For the applicable I/O type and power supply, refer to the table Pin Description.

20.3.5 Power Supplies

The 32.768 kHz crystal oscillator, the slow RC oscillator and the secure backup SRAM (SECURAM) are powered by VDDBU.

The main crystal oscillator, the main RC oscillator and all PLLs are powered by VDDANA.

The VDDOUT25 2.5V LDO regulator output must be connected to VDDANA and VDDDHY to fulfill the electrical requirements of these power inputs.

20.4 Special Functions in SFR/SFRBU

The backup power switch control is located in the SFRBU_PSWBU register.

The 2.5V LDO regulator control is located in the SFRBU_LDO25CR register.

21. System Controller Write Protection (SYSCWP)

21.1 Functional Description

21.1.1 System Controller Peripheral Mapping

Table 21-1. System Controller Peripheral Mapping

Offset	System Controller Peripheral	Name
0x000-0x00C	Reset Controller	RSTC
0x010-0x01C	Shutdown Controller	SHDWC
0x020-0x03C	Real Time Timer	RTT
0x050-0x05C	Slow Clock Controller	SCKC
0x060-0x0A4	General Purpose Backup Registers	GPBR
0x0A8-0xD8	Real Time Clock	RTC
0x0DC	Write Protection Mode Register	SYSC_WPMR
0x0E0	Write Protection Status Register	SYSC_WPSR
0x100-0x16C	Real Time Clock (tamper control and timestamp)	RTC
0x180-0x1AC	Watchdog Timer	WDT

21.1.2 Register Write Protection

To prevent any single software error from modifying the configuration of the Reset Controller (RSTC), Shutdown Controller (SHDWC), Real-time Timer (RTT), Slow Clock Controller (SCKC), General Purpose Backup Register (GPBR), Real-time Clock (RTC) and Watchdog Timer (WDT), some registers of these peripherals can be write-protected by setting the WPEN and/or WPITEN bits in the System Controller Write Protection Mode register (SYSC_WPMR).

Note: The WDT embeds additional write protection mechanisms.

When write protection is enabled, any attempt to write these registers is reported in the System Controller Write Protection Status register (SYSC_WPSR).

The following registers can be write-protected when SYSC_WPMR.WPEN=1:

- RSTC Mode Register
- SHDWC Mode Register
- SHDWC Wakeup Inputs Register
- SCKC Configuration Register
- RTC Control Register
- RTC Mode Register
- RTC Time Alarm Register
- RTC Calendar Alarm Register
- RTT Mode Register
- RTT Alarm Register
- RTT Modulo Selection Register
- GPBR Full Clear Register
- GPBR Registers

The following registers can be write-protected when SYSC_WPMR.WPITEN=1:

- RTC Interrupt Enable Register
- RTC Interrupt Disable Register

21.2 Register Summary

Offset	Name	Bit Pos.	7	6	5	4	3	2	1	0
0x00	SYSC_WPMR	31:24	WPKEY[23:16]							
		23:16	WPKEY[15:8]							
		15:8	WPKEY[7:0]							
		7:0							WPITEN	WPEN
0x04	SYSC_WPSR	31:24								
		23:16								
		15:8	WVSRC[7:0]							
		7:0								WPVS

21.2.1 SYSC Write Protection Mode Register

Name: SYSC_WPMR
Offset: 0x00
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
	WPKEY[23:16]							
Access	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	WPKEY[15:8]							
Access	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	WPKEY[7:0]							
Access	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
							WPITEN	WPEN
Access							R/W	R/W
Reset							0	0

Bits 31:8 – WPKEY[23:0] Write Protection Key

Value	Name	Description
0x535943	PASSWD	Writing any other value in this field aborts the write operation of the WPEN and WPITEN bits. Always reads as 0.

Bit 1 – WPITEN Write Protection RTC Interrupt Enable

Value	Description
0	Disables the write protection of the RTC_IER/RTC_IDR configuration registers if WPKEY corresponds to 0x535943 (“SYC” in ASCII).
1	Enables the write protection of the RTC_IER/RTC_IDR configuration registers if WPKEY corresponds to 0x535943 (“SYC” in ASCII).

Bit 0 – WPEN Write Protection Enable

Value	Description
0	Disables the write protection of the configuration registers if WPKEY corresponds to 0x535943 (“SYC” in ASCII).
1	Enables the write protection of the configuration registers if WPKEY corresponds to 0x535943 (“SYC” in ASCII).

21.2.2 SYSC Write Protection Status Register

Name: SYSC_WPSR
Offset: 0x04
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
	WVSRC[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
								WPVS
Access								R
Reset								0

Bits 15:8 – WVSRC[7:0] Write Violation Source
When bit WPVS is equal to 1, the field WVSRC indicates the register address offset at which a write access has been attempted.

Bit 0 – WPVS Write Protection Register Violation Status
WDT_CR, WDT_MR, RTT_MODR, RTC_IDR and RTC_IER can be write-protected but WPVS does not report any violation for these registers.

Value	Description
0	No write protection violation has occurred since the last read of SYSC_WPSR.
1	A write protection violation has occurred since the last read of SYSC_WPSR. The associated violation is reported into field WVSRC.

22. General Purpose Backup Registers (GPBR)

22.1 Description

The System Controller embeds 64 bits of General Purpose Backup registers organized as 2 32-bit registers.

SYS_GPBR0 to SYS_GPBR1 can be individually (each 32-bit part-select) read- and write-protected by configuring GPBR_MR. This register is write-once, which means that once it has been configured, the read or write protection is available until the loss of VBAT.

22.2 Embedded Characteristics

- 64 bits of General Purpose Backup Registers
- Read and Write Protection for SYS_GPBR0 to SYS_GPBR1

22.3 Register Summary

Offset	Name	Bit Pos.	7	6	5	4	3	2	1	0
0x00	GPBR_MR	31:24								
		23:16							GPBRRP1	GPBRRP0
		15:8								
		7:0							GPBRWP1	GPBRWP0
0x04	GPBR_FCLR	31:24								
		23:16								
		15:8								
		7:0								FCLR
0x08	SYS_GPBR0	31:24	GPBR_VALUE[31:24]							
		23:16	GPBR_VALUE[23:16]							
		15:8	GPBR_VALUE[15:8]							
		7:0	GPBR_VALUE[7:0]							
0x0C	SYS_GPBR1	31:24	GPBR_VALUE[31:24]

22.3.1 GPBR Mode Register

Name: GPBR_MR
Offset: 0x0
Reset: 0x00000000
Property: Read/Write-Once

This register is write-once. All bits are cleared at first power-up and on each loss of VBAT.

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode register (SYSC_WPMR).

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
							GPBRRP1	GPBRRP0
Access							R/W	R/W
Reset							0	0

							GPBRWP1	GPBRWP0
Access							R/W	R/W
Reset							0	0

Bits 16, 17 – GPBRRPx GPBRx Read Protection

Value	Description
0	The content of the corresponding GPBR register (32-bit part-select) can be read.
1	The corresponding GPBR register (32-bit part-select) always returns zero when read.

Bits 0, 1 – GPBRWPx GPBRx Write Protection

Value	Description
0	The corresponding GPBR register (32-bit part-select) can be written.
1	The corresponding GPBR register (32-bit part-select) is write-protected.

22.3.2 GPBR Full Clear Register

Name: GPBR_FCLR
Offset: 0x04
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode register (SYSC_WPMR).

All bits are cleared at first power-up and on each loss of VBAT.

Bit	31	30	29	28	27	26	25	24

Bit	7	6	5	4	3	2	1	0
								FCLR
Access								R/W
Reset								0

Bit 0 – FCLR Full Clear Enable

Value	Description
0	SYS_GPBR0 to SYS_GPBR1 are immediately cleared in case of fast wake-up pin tamper event.
1	All SYS_GPBRx are immediately cleared in case of fast wake-up pin tamper event.

22.3.3 General Purpose Backup Register x [x=0..1]

Name: SYS_GPBRx
Offset: 0x08 + x*0x04 [x=0..1]
Reset: 0x00000000
Property: R/W

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode register (SYSC_WPMR).

These registers are reset at first power-up and on each loss of VBAT.

Bit	31	30	29	28	27	26	25	24

Bits 31:0 – GPBR_VALUE[31:0] Value of SYS_GPBRx
Note: If an event has been detected on WKUP pins enabled for tamper event detection in the RTC, it is not possible to write to SYS_GPBRx as long as the event has not been cleared.

23. Dual Watchdog Timer (DWDT)

23.1 Description

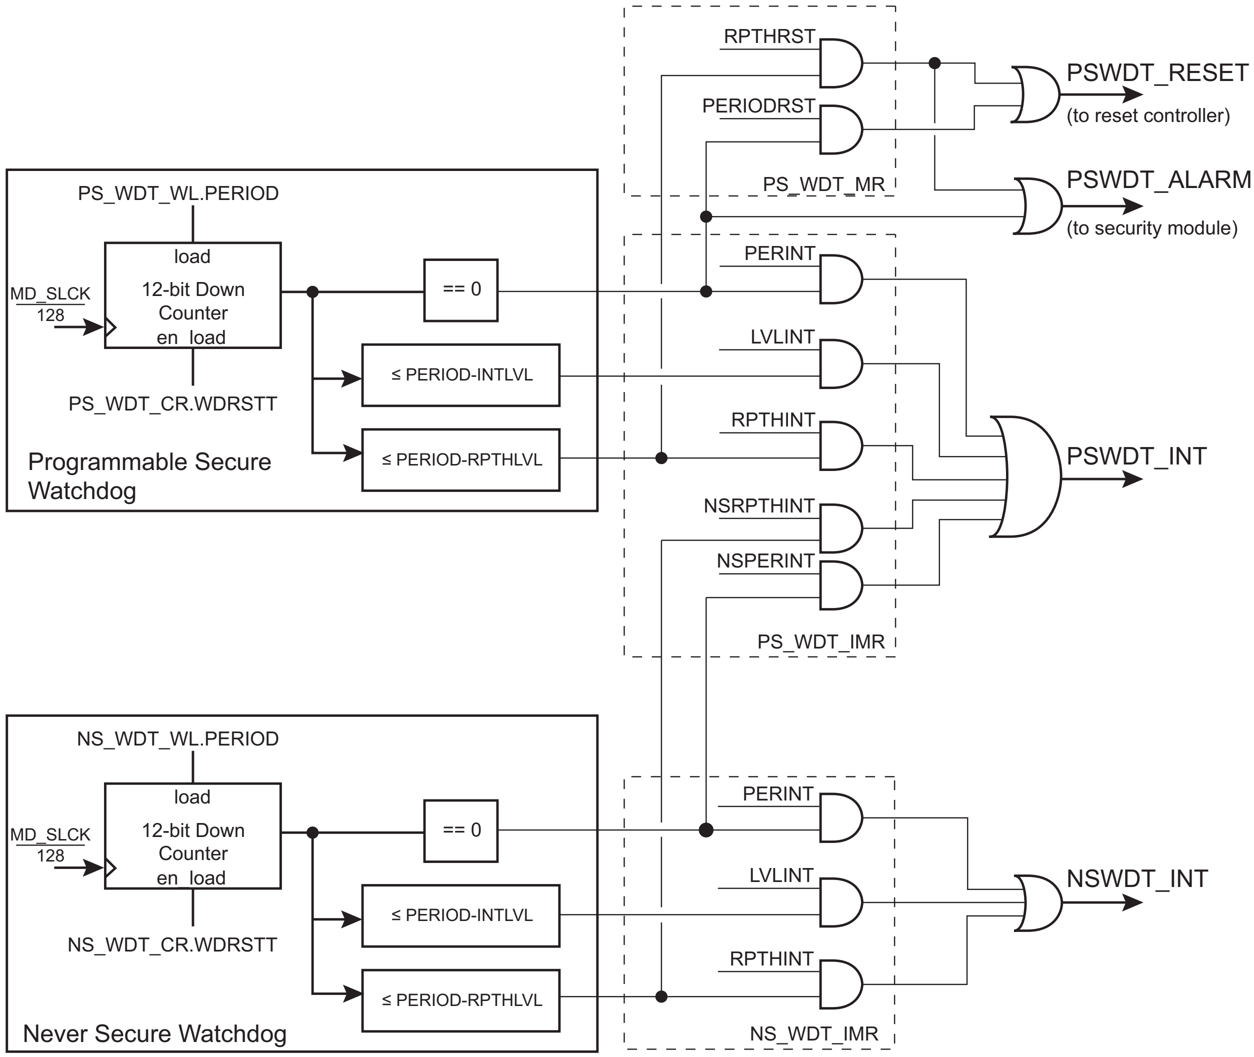
The Dual Watchdog Timer (DWDT) is used to prevent system lock-up if the software becomes trapped in a deadlock. It features two 12-bit down counters that allow two watchdog periods of up to 16 seconds (Monitoring Domain Slow Clock (MD_SLCK) around 32 kHz). In addition, it can be stopped while the processor is in Debug mode or Sleep mode (Idle mode).

23.2 Embedded Characteristics

- 12-bit Key-Protected Programmable Counter
- Watchdog Clock is Independent from Processor Clock
- Provides Reset or Interrupt Signals to the System
- Counter May be Stopped while the Processor is in Debug State or in Idle Mode

23.3 Block Diagram

Figure 23-1. DWDT Block Diagram



23.4 Functional Description

23.4.1 Configuration

The DWDT is used to prevent both secure and never secure system lock-up if the software becomes trapped in a deadlock. It is supplied with VDDCORE. It restarts with initial values on processor reset. It embeds two watchdogs:

- NSWDT–Never Secure Watchdog
- PSWDT–Programmable Secure Watchdog

Each watchdog is built around a 12-bit down counter, which is loaded with the value defined in the field PERIOD of the Window Level register (NS_WDT_WL or PS_WDT_WL). These registers use MD_SLCK divided by 128 to establish the maximum watchdog period to be 16 seconds (with a typical MD_SLCK of 32.768 kHz).

For each watchdog, the following parameters can be defined:

- PERIOD (Watchdog Period)–Load value of the down counter. Once the down counter reaches 0, a watchdog event is generated. For the PSWDT, a watchdog event leads to either a secure interrupt (if PS_WDT_IMR.PERINT is set to '1') or a reset (if PS_WDT_MR.PERIODRST is set to '1'). For the NSWDT, a watchdog event leads to either a secure interrupt (if PS_WDT_IMR.NSPERINT is set to '1') and/or a never secure interrupt (if NS_WDT_IMR.PERINT is set to '1').

- RPTH (Repeat Threshold)–A watchdog restart done before the repeat threshold is elapsed leads to a repeat violation. For the PSWDT, a repeat violation leads to either a secure interrupt (if PS_WDT_IMR.RPTHINT is set to '1') or a reset (if PS_WDT_MR.RPTHRST is set to '1'). For the NSWDT, a repeat violation leads to either a secure interrupt (if PS_WDT_IMR.NSRPTHINT is set to '1') or a never secure interrupt (if NS_WDT_IMR.RPTHINT is set to '1').
- LVLTH (Interrupt Threshold)–Threshold after which an interrupt is generated. For the PSWDT, a repeat violation leads to a secure interrupt (if PS_WDT_IMR.LVLINT is set to '1'). For the NSWDT, a repeat violation leads to a never secure interrupt (if NS_WDT_IMR.LVLINT is set to '1').

After a processor reset, the value of PERIOD is 0xFFF, corresponding to the maximum value of the counter with the external reset generation enabled (field PERIODRST at 1 after a backup reset). This means that watchdogs are running at reset, i.e., at power-up. The user can either disable the WDT by setting bit PS_WDT_MR.WDDIS and/or NS_WDT_MR.WDDIS to '1' or reprogram the WDTs to meet the maximum watchdog period the application requires.

The NSWDT and the PSWDT embed securities to avoid programming out of range values. The following inequality must always be respected, otherwise the configuration is cancelled:

$$\mathrm{RPTH} \leq \mathrm{LVLTH} < \mathrm{PERIOD}$$

Moreover, the PSWDT has the possibility to control the range of operation of the NSWDT. It can limit the period, the repeat threshold and the interrupt level of the NSWDT by programming NS_WDT_LVLLIM, NS_WDT_RLIM and NS_WDT_PLIM.

23.4.2 Watchdog Reload

In normal operation, the user reloads the watchdog at regular intervals before the down counter reaches 0, by setting PS_WDT_CR.WDRSTT or NS_WDT_CR.WDRSTT with the right KEY field. The watchdog counter is then immediately reloaded with the PERIOD value and restarted, and the MD_SLCK 128 divider is reset and restarted. Writing PS_WDT_CR or NS_WDT_CR with a wrong key has no effect.

Writing PS_WDT_MR, PS_WDT_WLR or PS_WDT_ILR immediately reloads the counter from PERIOD and restarts the MD_SLCK 128 divider of PSWDT.

Writing NS_WDT_MR, NS_WDT_WLR or NS_WDT_ILR immediately reloads the counter from PERIOD and restarts the MD_SLCK 128 divider of NSWDT.

23.4.3 Watchdog Lock

PS_WDT_MR and NS_WDT_MR can be written until a LOCKMR command is issued in the corresponding PS_WDT_CR or NS_WDT_CR. Once locked, only a processor reset resets PS_WDT_MR and NS_WDT_MR. As long as a WDT is not locked, writing NS_WDT_MR or PS_WDT_MR automatically reloads the corresponding Watchdog timer with the newly programmed mode parameters.

If the watchdog is restarted by writing into the corresponding Control register (PS_WDT_CR or NS_WDT_CR), the corresponding PS_WDT_MR or NS_WDT_MR must not be programmed during a period of time of three MD_SLCK periods following the PS_WDT_CR or NS_WDT_CR write access.

23.4.4 Repeat Threshold

A repeat threshold can be defined for each watchdog in order to protect against dead-locks that would repeatedly restart the watchdog. PS_WDT_WL.RPTH and NS_WDT_WL.RPTH define the minimum number of cycles to wait after a watchdog restart before the watchdog can be restart again. If a watchdog restart occurs before this limit is reached, a repeat threshold failure is asserted and the PS_WDT_ISR.RPTHINT and/or the NS_WDT_ISR.RPTHINT bit are/is set to one. This feature can be disabled by programming a null RPTH value. In such a configuration, restarting the Watchdog Timer is permitted in the whole range [0; PERIOD] and does not generate an error. This is the default configuration on reset (RPTH is null).

23.4.5 Watchdog Reset Order

Only the Programmable Secure watchdog (PSWDT) can send a Watchdog Reset Order to the Reset Controller. If the down counter reaches 0 or if the watchdog is restarted before reaching the RPTH threshold limit, a Watchdog Reset Order is sent to the Reset Controller if PS_WDT_MR.PERIODRST and/or PS_WDT_MR.RPTHRST are set to '1'.

23.4.6 Watchdog Interrupt

If PS_WDT_IMR.RPTHINT is set to '1' and a repeat threshold violation occurs in the PSWDT, a programmable secure interrupt is generated.

If NS_WDT_IMR.RPTHINT is set to '1' and a repeat threshold violation occurs in the NSWDT, a never secure interrupt is generated.

If PS_WDT_IMR.NSRPTHINT is set to '1' and a repeat threshold violation occurs in the NSWDT, a programmable secure interrupt is generated.

If a reset is generated or if PS_WDT_SR or NS_WDT_SR is read, the status bits are reset, the interrupt is cleared, and the “wdt_fault” signal to the reset controller is deasserted.

23.4.7 Security Module

Both watchdogs are connected to the security module. If a down counter reaches 0, an alarm is systematically sent to the security module (whatever the configuration of interrupts and resets).

If the PSWDT is restarted before the RPTH threshold, an alarm is sent to the security module only if PS_WDT_MR.RPTHRST is set to ‘1’. Nevertheless, this does not cancel the reset operation.

23.4.8 Watchdog Halt

While the processor is in Debug state or in Sleep mode (including ULP mode 1 and 2), the counter may be stopped depending on the value programmed for the bits WDIDLEHLT and WDDBGHLT in PSWDT_MR or NSWDT_MR.

23.4.9 Timing Diagrams

Figure 23-2. Never Secure Watchdog Timing Diagram

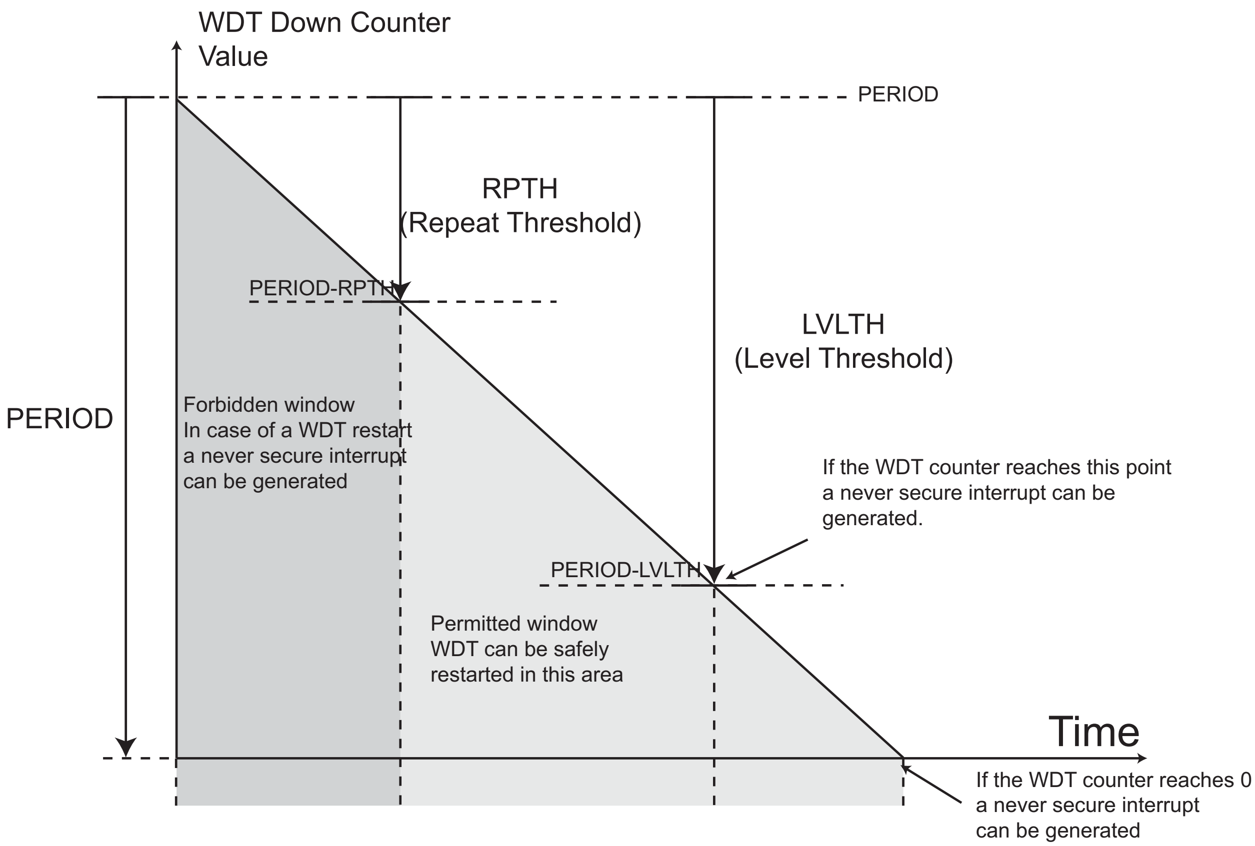


Figure 23-3. Programmable Secure Watchdog Timing Diagram

23.5.1 DWDT Never Secure Watchdog Timer Control Register

Name: NS_WDT_CR
Offset: 0x00
Reset: –
Property: Write-only

Note: The NS_WDT_CR register values must not be modified within three MD_SLCK periods following a restart of the watchdog performed by a write access in NS_WDT_CR. Any modification causes the watchdog to trigger an end of period earlier than expected.

Bits 31:24 – KEY[7:0] Password

Value	Name	Description
0xA5	PASSWD	Writing any other value in this field aborts the write operation.

Bit 4 – LOCKMR Lock Mode Register Write Access

Value	Description
0	No effect.
1	Locks the configuration registers if KEY is written to 0xA5. Write accesses to NS_WDT_MR, NS_WDT_WL and NS_WDT_IL have no effect.

Bit 0 – WDRSTT Watchdog Restart

Value	Description
0	No effect.
1	Restarts the watchdog if KEY is written to 0xA5.

23.5.2 DWDT Never Secure Watchdog Timer Mode Register

Name: NS_WDT_MR
Offset: 0x04
Reset: 0x00000030
Property: Read/Write

Write access to this register has no effect if the LOCKMR command is issued in NS_WDT_CR (unlocked on hardware reset).

The NS_WDT_MR register values must not be modified within three MD_SLCK periods following a restart of the watchdog performed by a write access in NS_WDT_CR. Any modification will cause the watchdog to trigger an end of period earlier than expected.

Access	R	R	R	R	R	R	R	R
Reset	1	1	1	1	1	1	1	1

Bits 11:0 – COUNTER[11:0] Watchdog Down Counter Value
Current value of the watchdog down counter.
Due to the asynchronous operation of the DWDT with respect to the rest of the chip, to be certain that the value read in this is valid and stable, it is necessary to read this register twice. If the data is the same both times, then it is valid. Therefore, a minimum of two and a maximum of three accesses are required.

23.5.4 DWDT Never Secure Watchdog Timer Window Level Register

Name: NS_WDT_WL
Offset: 0x0C
Reset: 0x00000FFF
Property: Read/Write

Bit	31	30	29	28	27	26	25	24

Bit 2 – LVLINT Interrupt Level Threshold Interrupt Enable

Value	Description
0	No level threshold failure has occurred in the never secure watchdog since the last read of NS_WDT_ISR.
1	At least one level threshold failure has occurred in the never secure watchdog since the last read of NS_WDT_ISR.

Bit 1 – RPTHINT Repeat Threshold Interrupt Enable

Value	Description
0	No repeat threshold failure has occurred in the never secure watchdog since the last read of NS_WDT_ISR.
1	At least one repeat threshold failure has occurred in the never secure watchdog since the last read of NS_WDT_ISR.

Bit 0 – PERINT Period Interrupt Status

Value	Description
0	No period failure has occurred in the never secure watchdog since the last read of NS_WDT_ISR.
1	At least one period failure has occurred in the never secure watchdog since the last read of NS_WDT_ISR.

23.5.9 DWDT Never Secure Watchdog Interrupt Mask Register

Name: NS_WDT_IMR
Offset: 0x20
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
						LVLINT	RPTHINT	PERINT
Access						R	R	R
Reset						0	0	0

Bit 2 – LVLINT Interrupt Level Threshold Interrupt Mask

Value	Description
0	Interrupt on LVLINT is disabled.
1	Interrupt on LVLINT is enabled.

Bit 1 – RPTHINT Repeat Threshold Interrupt Mask

Value	Description
0	Interrupt on RPTHINT is disabled.
1	Interrupt on RPTHINT is enabled.

Bit 0 – PERINT Period Interrupt Mask

Value	Description
0	Interrupt on PERINT is disabled.
1	Interrupt on PERINT is enabled.

23.5.10 DWDT Programmable Secure Watchdog Timer Control Register

Name: PS_WDT_CR
Offset: 0x1180
Reset: –
Property: Write-only

Register values must not be modified within three MD_SLCK periods following a restart of the watchdog performed by a write access in PS_WDT_CR. Any modification causes the watchdog to trigger an end of period earlier than expected.

Bit	31	30	29	28	27	26	25	24
	KEY[7:0]							
Access	W	W	W	W	W	W	W	W
Reset	–	–	–	–	–	–	–	–

Bit	7	6	5	4	3	2	1	0
				LOCKMR				WDRSTT
Access				W				W
Reset				–				–

Bits 31:24 – KEY[7:0] Password

Value	Name	Description
0xA5	PASSWD	Writing any other value in this field aborts the write operation.

Bit 4 – LOCKMR Lock Mode Register Write Access

Value	Description
0	No effect.
1	Locks the configuration registers if KEY is written to 0xA5. Write accesses to PS_WDT_MR, PS_WDT_WL and PS_WDT_IL have no effect.

Bit 0 – WDRSTT Watchdog Restart

Value	Description
0	No effect.
1	Restarts the watchdog if KEY is written to 0xA5.

23.5.11 DWDT Programmable Secure Watchdog Timer Mode Register

Name: PS_WDT_MR
Offset: 0x1184
Reset: 0x00000030
Property: Read/Write

Write access to this register has no effect if the LOCKMR command is issued in PS_WDT_CR (unlocked on hardware reset).

The PS_WDT_MR register values must not be modified within three MD_SLCK periods following a restart of the watchdog performed by a write access in PS_WDT_CR. Any modification will cause the watchdog to trigger an end of period earlier than expected.

Bit	31	30	29	28	27	26	25	24
			WDIDLEHLT	WDDBGHLT				
Access			R/W	R/W				
Reset			0	0				

Bit	23	22	21	20	19	18	17	16

			RPTHRST	PERIODRST				
Access			R/W	R/W				
Reset			1	1				

Bit 29 – WDIDLEHLT Watchdog Idle Halt

Value	Description
0	The watchdog runs when the system is in Idle state.
1	The watchdog stops when the system is in Idle state.

Bit 28 – WDDBGHLT Watchdog Debug Halt

Value	Description
0	The watchdog runs when the processor is in Debug state.
1	The watchdog stops when the processor is in Debug state.

Bit 12 – WDDIS Watchdog Disable

Value	Description
0	Enables the Watchdog Timer.
1	Disables the Watchdog Timer.

Bit 5 – RPTHRST Repeat Threshold Reset

Value	Description
0	No reset is generated if the watchdog is restarted before the RPTH threshold
1	A reset is generated if the watchdog is restarted before the RPTH threshold

Bit 4 – PERIODRST Period Reset

Value	Description
0	No reset is generated if the watchdog down counter reaches 0

Value	Description
1	A reset is generated once the watchdog down counter reaches 0

23.5.12 DWDT Programmable Secure Watchdog Timer Value Register

Name: PS_WDT_VR
Offset: 0x1188
Reset: 0x00000000
Property: Read-only

Bit	7	6	5	4	3	2	1	0
	COUNTER[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bits 11:0 – COUNTER[11:0] Watchdog Down Counter Value
Current value of the watchdog down counter.
Due to the asynchronous operation of the DWDT with respect to the rest of the chip, to be certain that the value read in this is valid and stable, it is necessary to read this register twice. If the data is the same both times, then it is valid. Therefore, a minimum of two and a maximum of three accesses are required.

23.5.13 DWDT Programmable Secure Watchdog Timer Window Level Register

Name: PS_WDT_WL
Offset: 0x118C
Reset: 0x00000FFF
Property: Read/Write

Bit 4 – NSRPTHINT Never Secure Repeat Threshold Interrupt Status

Value	Description
0	No never secure repeat threshold failure has occurred in the programmable secure watchdog since the last read of PS_WDT_ISR.
1	At least one never secure repeat threshold failure occurred in the programmable secure watchdog since the last read of PS_WDT_ISR.

Bit 3 – NSPERINT Never Secure Period Interrupt Status

Value	Description
0	No never secure period failure has occurred in the programmable secure watchdog since the last read of PS_WDT_ISR.
1	At least one never secure period failure occurred in the programmable secure watchdog since the last read of PS_WDT_ISR.

Bit 2 – LVLINT Interrupt Level Threshold Interrupt Status

Value	Description
0	No level threshold failure has occurred in the Programmable secure watchdog since the last read of PS_WDT_ISR.
1	At least one level threshold failure has occurred in the Programmable secure watchdog since the last read of PS_WDT_ISR.

Bit 1 – RPTHINT Repeat Threshold Interrupt Status

Value	Description
0	No repeat threshold failure has occurred in the Programmable secure watchdog since the last read of PS_WDT_ISR.
1	At least one repeat threshold failure has occurred in the Programmable secure watchdog since the last read of PS_WDT_ISR.

Bit 0 – PERINT Period Interrupt Status

Value	Description
0	No period failure has occurred in the Programmable secure watchdog since the last read of PS_WDT_ISR.
1	At least one period failure has occurred in the Programmable secure watchdog since the last read of PS_WDT_ISR.

23.5.18 DWDT Programmable Secure Watchdog Interrupt Mask Register

Name: PS_WDT_IMR

Bits 27:16 – PERMAX[11:0] Period Maximum
Defines the maximum value that can be applied to NS_WDT_WL.PERIOD.
If the currently defined PERIOD value of the NS_WDT is higher than the PERMAX to be configured, PERMAX value is applied to PERIOD.

Bits 11:0 – PERMIN[11:0] Period Minimum
Defines the minimum value that can be applied to NS_WDT_WL.PERIOD.
If the currently defined PERIOD value of the NS_WDT is lower than the PERMIN to be configured, PERMIN value is applied to PERIOD.

24. Reset Controller (RSTC)

24.1 Description

The Reset Controller (RSTC) handles all the resets of the system without any external components. It reports which reset occurred last.

The RSTC is driven by Power-on Reset (POR) cells, software, an external reset pin, and peripheral events.

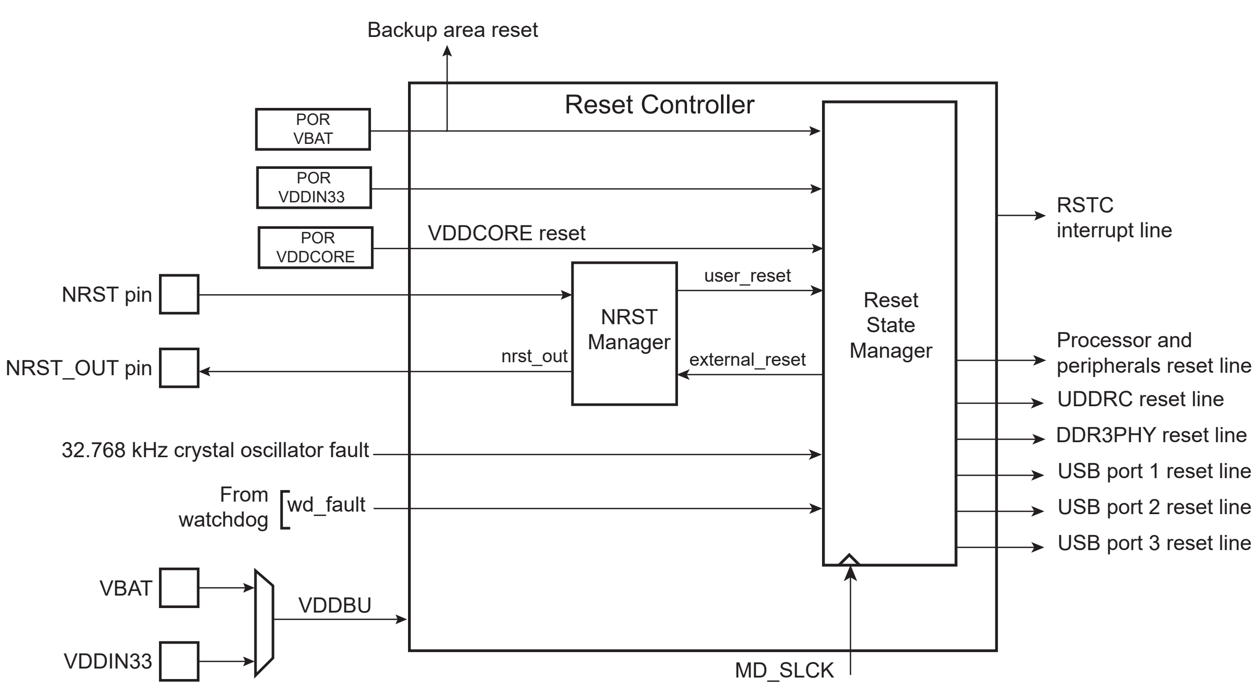
The RSTC drives simultaneously the External reset and the Peripheral and Processor resets.

24.2 Embedded Characteristics

- Driven by Embedded Power-on Reset, Software, External Reset Pin and Peripheral Events
- Management of All System Resets, Including
  - External devices through an I/O multiplexed output reset pin
  - Processor
  - Peripheral set
- Reset Source Status
  - Status of the last reset
  - Either VDDCORE and VBAT POR reset, Software reset, User reset, Watchdog reset, 32.768 kHz Crystal Oscillator, ULP2 Low-power mode exit

24.3 Block Diagram

Figure 24-1. RSTC Block Diagram



24.4 Functional Description

The RSTC is made up of an NRST manager and a reset state manager. The RSTC clock is MD_SLCK (monitoring domain slow clock). The RSTC generates the following reset signals:

- Processor reset line (also resets the Watchdog Timer)
- Entire set of embedded peripherals reset line
- NRST_OUT pin

Note: Processor and peripheral reset lines are driven in the same way.

These internal reset signals are asserted by the RSTC, either on events generated by peripherals, events on NRST pin, or on software action. The reset state manager controls the generation of reset signals and drives the NRST_OUT pin when required.

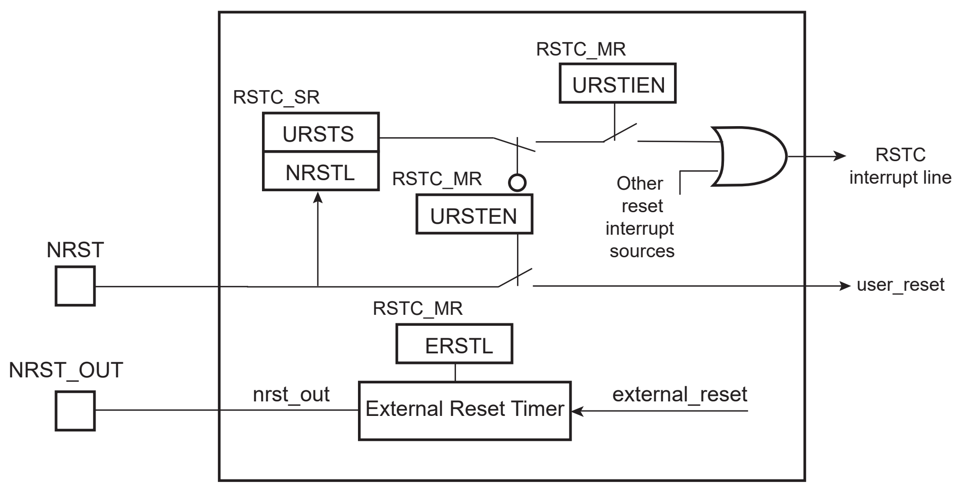
The NRST manager asserts the NRST_OUT pin during a programmable time, thus controlling external device resets.

The Mode register (RSTC_MR), used to configure the RSTC, is powered by VDDBU.

24.4.1 NRST Manager

The NRST manager samples the NRST pin and drives the NRST_OUT pin low when required by the reset state manager. See the following figure.

Figure 24-2. NRST Pin Management



24.4.1.1 NRST Signal or Interrupt

The NRST manager handles the NRST input line asynchronously if RSTC_MR.URSTASYNC =1. When the NRST input is low, a user reset is immediately reported to the Reset State manager and the internal reset signals are asserted even if there is a clock failure on MD_SLCK (safe reset).

The NRST manager handles the NRST input line synchronously if RSTC_MR.URSTASYNC=0. When the line is low, it is first resynchronized on slow clock before it is reported to the Reset State manager. In both cases, when the NRST goes from low to high, the internal reset is synchronized with the monitoring slow clock to provide a safe internal de-assertion of reset (if enabled).

If RSTC_MR.URSTEN=0, the assertion of the NRST input pin does not trigger a VDDCORE domain reset.

The level of the pin NRST is reported in NRSTL of the Status register (RSTC_SR).

As soon as the pin NRST is asserted (low level), RSTC_SR.URSTS=1. This bit is cleared on read.

If RSTC_MR.URSTIEN=1, the assertion of NRST pin triggers an interrupt rather than a VDDCORE reset.

24.4.1.2 NRST_OUT External Reset Control

The RSTC can be configured to assert the external reset line (NRST_OUT). The NRST_OUT pin is driven low for a time programmed by RSTC_MR.ERSTL. This assertion duration lasts $2^{(ERSTL+1)}$ MD_SLCK cycles. This assertion duration time is in the range of 60 µs to 2 seconds. If ERSTL=0, a two slow clock period duration is generated on the NRST_OUT pin.

This feature allows the NRST_OUT line to be compliant with any external devices connected on the system reset (i.e., when external devices require a longer start-up time than the processor system).

24.4.1.3 USB Reset Control

The RSTC controls the resets of the USB Controller through bit USBRSTx of the Generic Reset register (RSTC_GRSTR).

24.4.1.4 DDR Reset Control

The RSTC controls the reset of the DDR Controller through RSTC_GRSTR.DDRRST.

24.4.2 Reset States

The reset state manager handles the different reset sources and generates the internal reset signals. It reports the reset status in RSTC_SR.RSTTYP. RSTC_SR.RSTTYP is updated when the Processor reset is released.

If more than one reset event occurred since the last read of RST_SR, the field RSTTYP reports the first reset that occurred.

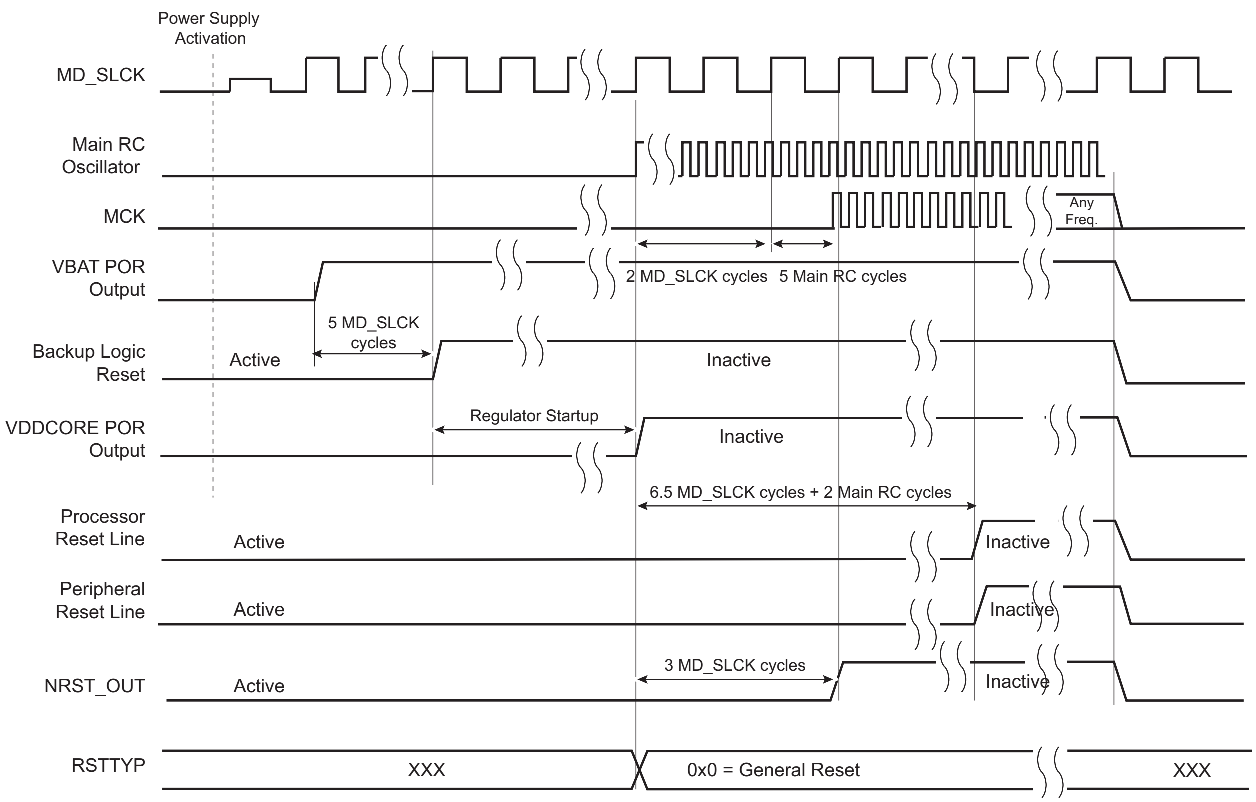
24.4.2.1 General Reset

A general reset occurs when a VBAT Power-on reset is detected. The internal VDDCORE reset signal is asserted when a general reset occurs. All the reset signals are released and RSTC_SR.RSTTYP reports a general reset.

The NRST_OUT line rises two cycles after the VDDCORE reset line, as ERSTL defaults at value 0x0.

The following figure shows how the general reset affects the reset signals.

Figure 24-3. General Reset Timing Diagram (VDDBU supplied by VBAT)



24.4.2.2 Backup Exit Reset

A Backup reset occurs when the chip exits from Backup mode. While exiting Backup mode, the VDDCORE reset signal is de-asserted.

RSTC_SR.RSTTYP is updated to report a Backup reset.

24.4.2.3 32.768 kHz Crystal Oscillator Failure Detection Reset

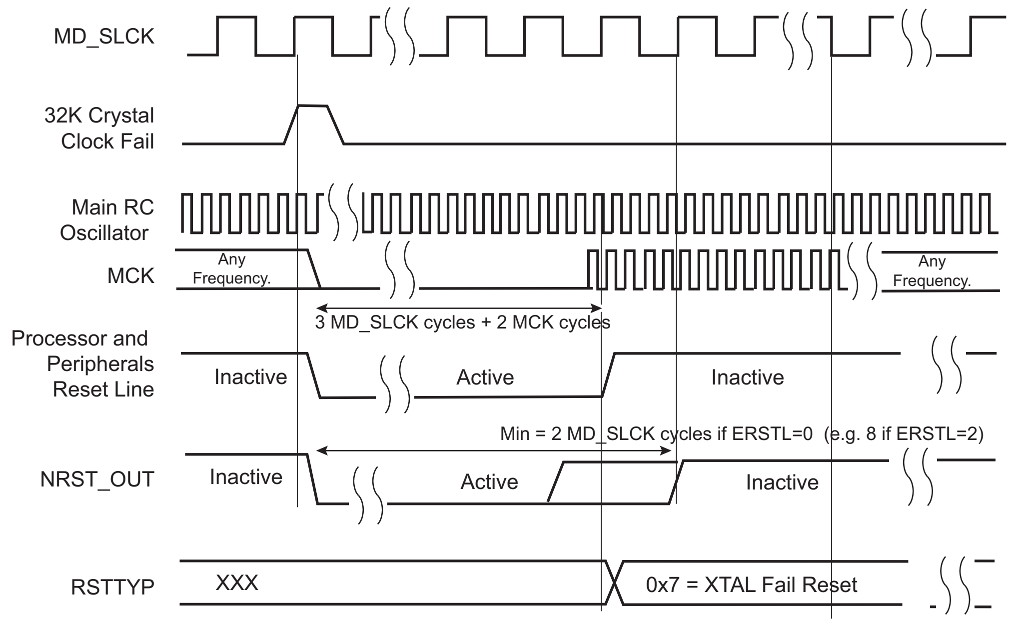
The 32.768 kHz Crystal Oscillator Failure Detection reset is done when the 32.768 kHz crystal oscillator frequency monitoring circuitry in the PMC detects a failure and RSTC_MR.SCKSW is written to '1'. This reset lasts three slow clock cycles.

When RSTC_MR.SCKSW is written to ‘0’, the 32.768 kHz crystal oscillator fault has no impact on the RSTC.

During the 32.768 kHz Crystal Oscillator Failure Detection reset, the Processor reset and the Peripheral reset are asserted. The NRST_OUT line is also asserted, depending on the value of RSTC_MR.ERSTL.

When the 32.768 kHz crystal oscillator failure generates a VDDCORE reset, PMC_SR.XT32KERR is automatically cleared by the Peripheral and Processor resets.

Figure 24-4. 32.768 kHz Crystal Oscillator Failure Detection Reset Timing Diagram

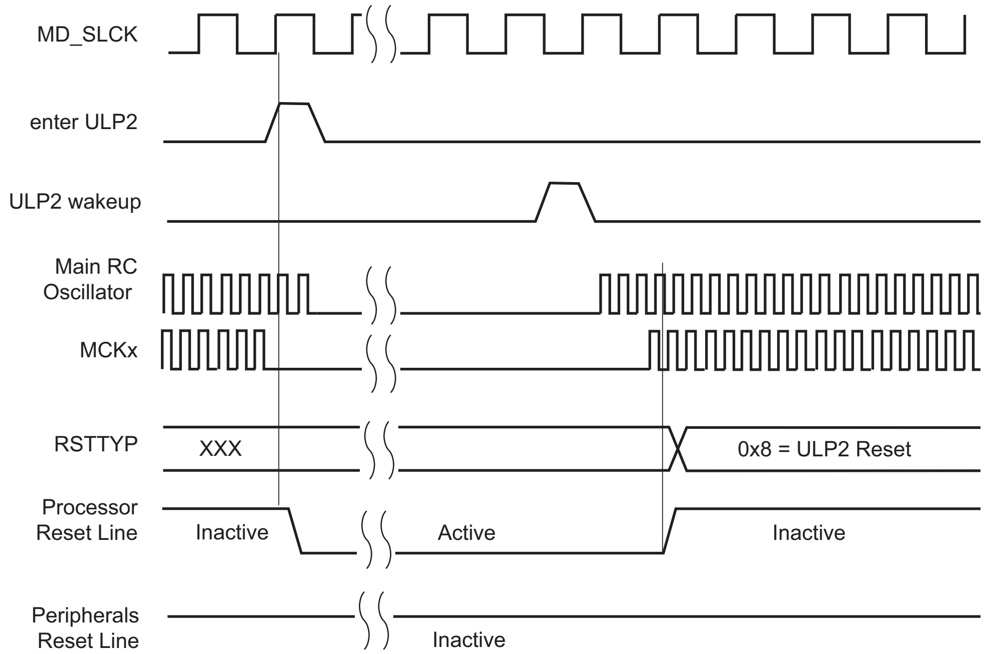


24.4.2.4 ULP Mode 2 Reset

The ULP Mode 2 reset is entered when a WFE event occurs while CKGR_MOR.ULP2 is set to ‘1’ in the PMC.

When this reset occurs, only the Processor reset is asserted. The VDDCPU power supply can be switched off during the ULP mode 2 (refer to “ULP Mode 2” in the section “Power Management Controller (PMC)”.

Figure 24-5. ULP Mode 2 Reset Timing Diagram



24.4.2.5 Watchdog Reset

The Watchdog reset is entered when a watchdog fault occurs. This reset lasts three MD_SLCK cycles.

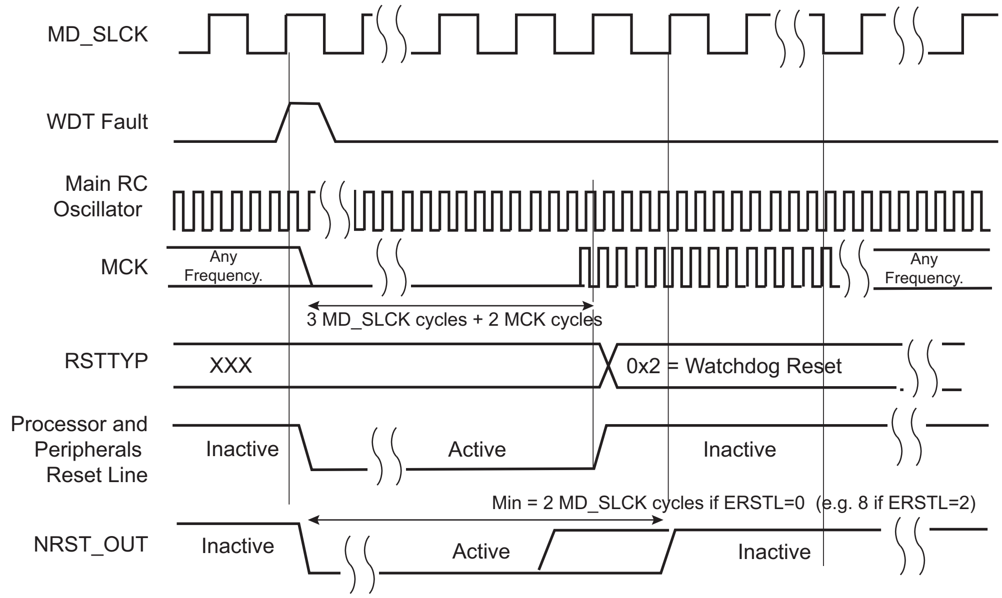
When in Watchdog reset, the Processor reset and the Peripheral reset are asserted. The NRST_OUT line is also asserted, depending on the value of RSTC_MR.ERSTL. However, the resulting low level on NRST_OUT does not result in a User reset state.

The WDT is reset by the Processor reset signal. As the watchdog fault always causes a Processor reset if WDT_MR.WDRSTEN is written to ‘1’, the WDT is always reset after a Watchdog reset, and the Watchdog is enabled by default and with a period set to a maximum.

When WDT_MR.WDRSTEN is written to ‘0’, the watchdog fault has no impact on the RSTC.

After a watchdog overflow occurs, the report on the RSTC_SR.RSTTYP may differ (either WDT_RST or USER_RST) depending on the external components driving the NRST pin. For example, if the NRST line is driven through a resistor and a capacitor (NRST pin debouncer), the reported value is USER_RST if the low-to-high transition is greater than one MD_SLCK cycle.

Figure 24-6. Watchdog Reset Timing Diagram



24.4.2.6 Software Reset

The RSTC offers commands to assert the different reset signals. These commands are performed by writing the Control register (RSTC_CR) with the following bits at ‘1’:

- RSTC_CR.PROCRST: Writing a ‘1’ to PROCRST resets the processor and all the embedded peripherals, including the memory system and, in particular, the Remap Command.
- RSTC_CR.EXTRST: Writing a ‘1’ to EXTRST asserts low the NRST_OUT pin during a time defined by the field RSTC_MR.ERSTL.

The Software reset is entered if at least one of these bits is written to ‘1’ by the software. All these commands can be performed independently or simultaneously. The Software reset lasts three MD_SLCK cycles.

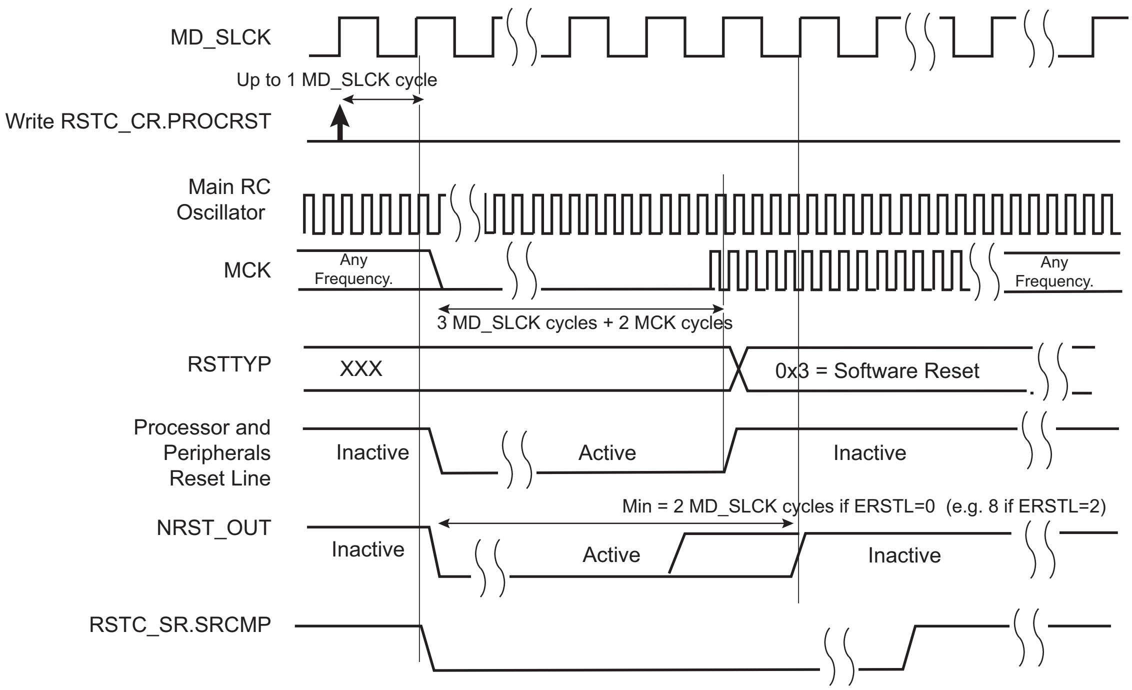
The internal reset signals are asserted as soon as the register write is performed. They are released when the Software reset has ended, i.e., synchronously to MD_SLCK.

If EXTRST is written to ‘1’, the NRST_OUT pin is asserted depending on the configuration of RSTC_MR.ERSTL. However, the resulting falling edge on NRST_OUT does not lead to a User reset.

If and only if the RSTC_CR.PROCRST is written to ‘1’, the RSTC reports the software status in field RSTC_SR.RSTTYP. Other software resets are not reported in RSTTYP.

As soon as a software operation is detected, RSTC_SR.SRCMP is written to ‘1’. SRCMP is cleared at the end of the Software reset. No other Software reset can be performed while SRCMP=‘1’, and writing any value in the RSTC_CR has no effect.

Figure 24-7. Software Reset Timing Diagram (PROCRST)



24.4.2.7 User Reset

The User reset is entered when a low level is detected on the NRST pin and RSTC_MR.URSTEN =1. If URSTASYNC=1, a falling edge of the NRST input signal immediately asserts internal reset lines. If URSTASYNC=0, the NRST input signal is resynchronized and internal reset lines are asserted once a falling edge has been detected on the resynchronized NRST input signal.

The Processor reset and the Peripheral reset are asserted.

The User reset is released when NRST rises, after a two-cycle resynchronization time and a 2-cycle processor start-up. The processor clock is re-enabled as soon as NRST is confirmed high.

When the Processor reset signal is released, RSTC_SR.RSTTYP is loaded with the value 0x4, indicating a User reset.

The NRST manager ensures that the NRST_OUT line is asserted as programmed in the field ERSTL. However, if NRST is driven low externally, the internal reset lines remain asserted until NRST rises.

Figure 24-8. User Reset State (URSTASYNC = '0')

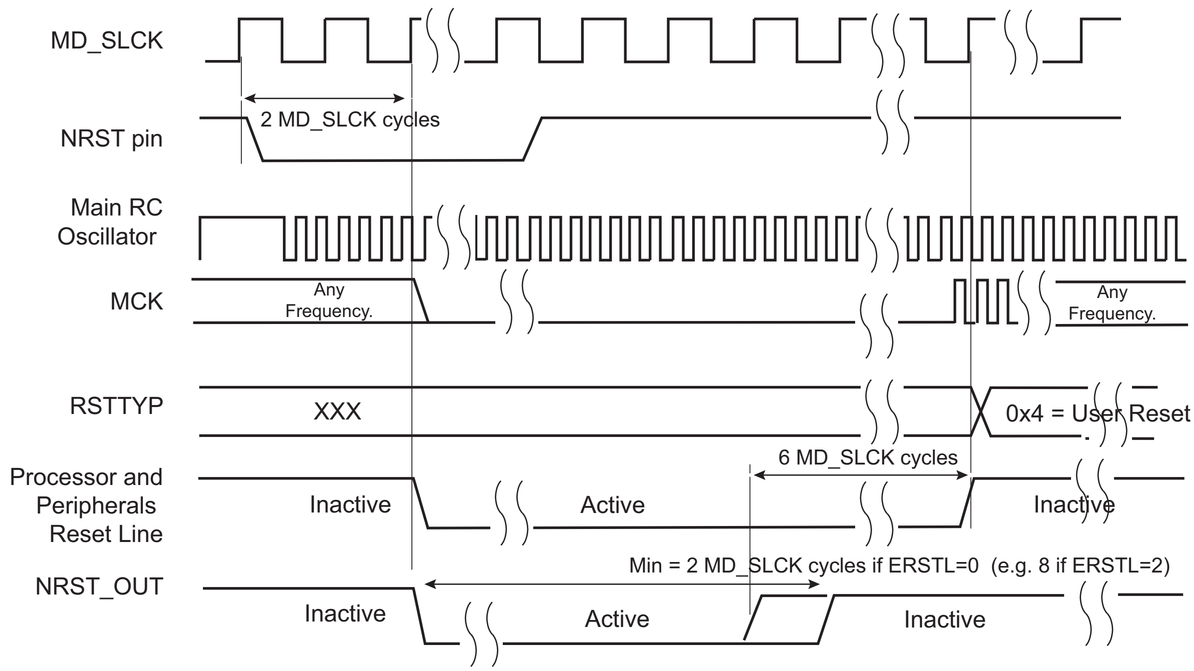


Figure 24-9. User Reset State (URSTASYNC = '1')

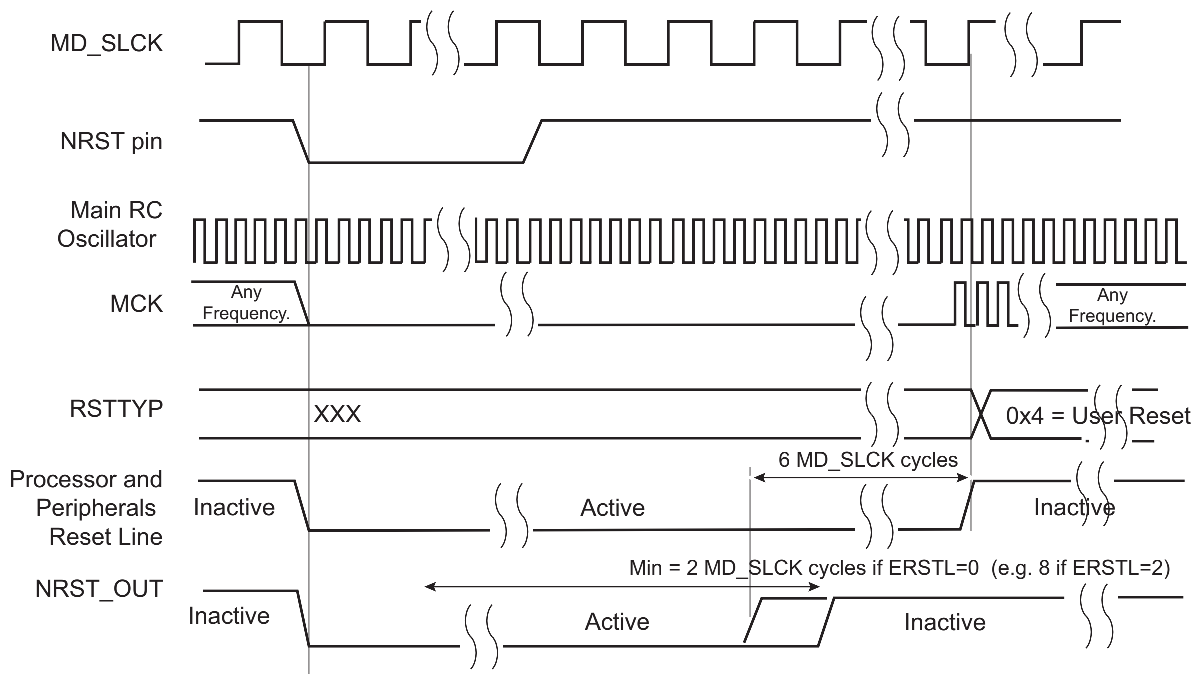

24.4.3 Reset State Priorities

The reset state manager manages the priorities among the different reset sources. The resets are listed in order of priority as follows:

1. General reset
2. Backup reset
3. 32.768 kHz Crystal Failure Detection reset
4. Watchdog reset

5. Software reset
6. User reset

Specific cases are listed below:

- When in User reset:
  – A watchdog event is impossible because the WDT is being reset by the Processor reset signal.
  – A Software reset is impossible, since the Processor reset is being activated.
- When in Software reset:
  – A watchdog event has priority over the current state.
  – The NRST has no effect.
- When in Watchdog reset:
  – The Processor reset is active and so a Software reset cannot be programmed.
  – A User reset cannot be entered.

24.5 Register Summary

Offset	Name	Bit Pos.	7	6	5	4	3	2	1	0
0x00	RSTC_CR	31:24	KEY[7:0]							
		23:16								
		15:8								
		7:0					EXTRST			PROCRST
0x04	RSTC_SR	31:24								
		23:16							SRCMP	NRSTL
		15:8					RSTTYP[3:0]			
		7:0								URSTS

		23:16								
		15:8					ERSTL[3:0]			
		7:0				URSTIEN		URSTASYNC	SCKSW	URSTEN
0x0C ... 0xE3	Reserved									
0xE4	RSTC_GRSTR	31:24								
		23:16								
		15:8								
		7:0		USB_RST3	USB_RST2	USB_RST1		DDR_PHY_RST		DDR_RST

24.5.1 RSTC Control Register

Name: RSTC_CR
Offset: 0x00
Reset: –
Property: Write-only

Bit	31	30	29	28	27	26	25	24
	KEY[7:0]							
Access	W	W	W	W	W	W	W	W
Reset	–	–	–	–	–	–	–	–
Bit	23	22	21	20	19	18	17	16
Access								
Reset								
Bit	15	14	13	12	11	10	9	8
Access								
Reset								
Bit	7	6	5	4	3	2	1	0
					EXTRST			PROCRST
Access					W			W
Reset					–			–

Bits 31:24 – KEY[7:0] System Reset Key

Value	Name	Description
0xA5	PASSWD	Writing any other value in this field aborts the write operation.

Bit 3 – EXTRST External Reset

Value	Description
0	No effect.
1	If KEY = 0xA5, asserts the NRST_OUT pin.

Bit 0 – PROCRST Processor Reset

Value	Description
0	No effect.
1	If KEY = 0xA5, resets the processor and all the embedded peripherals.

24.5.2 RSTC Status Register

Name: RSTC_SR
Offset: 0x04
Reset: 0x00000000
Property: Read-only

The reset value assumes that a general reset has been performed, subject to change if other types of reset are generated.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
							SRCMP	NRSTL
Access							R	R
Reset							0	0

Bit	15	14	13	12	11	10	9	8
					RSTTYP[3:0]			
Access					R	R	R	R
Reset					0	0	0	0

Bit	7	6	5	4	3	2	1	0
								URSTS
Access								R
Reset								0

Bit 17 – SRCMP Software Reset Command in Progress
When set, this bit indicates that a software reset command is in progress and that no further software reset should be performed until the end of the current one. This bit is automatically cleared at the end of the current software reset.

Value	Description
0	No software command is being performed by the RSTC. The RSTC is ready for a software command.
1	A software reset command is being performed by the RSTC. The RSTC is busy.

Bit 16 – NRSTL NRST Pin Level
Registers the NRST pin level sampled on each MCK rising edge.

Bits 11:8 – RSTTYP[3:0] Reset Type
This field reports the cause of the last processor reset. Reading RSTC_SR does not reset this field.

Value	Name	Description
0	GENERAL_RST	First power-up reset
1	BACKUP_RST	Return from Backup mode
2	WDT_RST	Watchdog fault occurred
3	SOFT_RST	Processor reset required by the software
4	USER_RST	NRST pin detected low
5	–	Reserved
6	–	Reserved
7	SLCK_XTAL_RST	32.768 kHz crystal failure detection fault occurred
8	ULP2_RST	ULP Mode 2 reset

Bit 0 – URSTS User Reset Status
A high-to-low transition of the NRST pin sets URSTS. This transition is also detected on the MCK rising edge. If the user reset is disabled (RSTC_MR.URSTEN = 0) and if the interrupt is enabled by RSTC_MR.URSTIEN, URSTS triggers an interrupt. Reading RSTC_SR resets URSTS and clears the interrupt.

Value	Description
0	No high-to-low edge on NRST happened since the last read of RSTC_SR.
1	At least one high-to-low transition of NRST has been detected since the last read of RSTC_SR.

24.5.3 RSTC Mode Register

Name: RSTC_MR
Offset: 0x08
Reset: 0x00000001
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode Register (SYSC_WPMR).

Bit	31	30	29	28	27	26	25	24
	KEY[7:0]							
Access	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	–

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
					ERSTL[3:0]			
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bit	7	6	5	4	3	2	1	0
				URSTIEN		URSTASYNC	SCKSW	URSTEN
Access				R/W		R/W	R/W	R/W
Reset				0		0	0	1

Bits 31:24 – KEY[7:0] Write Access Password

Value	Name	Description
0xA5	PASSWD	Writing any other value in this field aborts the write operation. Always reads as 0.

Bits 11:8 – ERSTL[3:0] External Reset Length
This field defines the external reset length. The external reset pin RST_OUT is asserted during a time of $2^{(ERSTL+1)}$ MD_SLCK cycles. This allows assertion duration to be programmed between 60 µs and 2 seconds. Note that synchronization cycles must also be considered when calculating the actual reset length as previously described.

Bit 4 – URSTIEN User Reset Interrupt Enable

Value	Description
0	RSTC_SR.USRTS at ‘1’ has no effect on the RSTC interrupt line.
1	RSTC_SR.USRTS at ‘1’ asserts the RSTC interrupt line if URSTEN = 0.

Bit 2 – URSTASYNC User Reset Asynchronous Control
See NRST Signal or Interrupt for important information on the use of URSTASYNC.

Value	Description
0	The NRST input signal is managed synchronously.
1	The NRST input signal is managed asynchronously. **Note:** This mode cannot be selected if the external bus interface drives an SDR/DDR memory device and another memory on the same bus.

Bit 1 – SCKSW Slow Clock Switching

Value	Description
0	The detection of a 32.768 kHz crystal failure has no effect.
1	The detection of a 32.768 kHz crystal failure resets the logic supplied by VDDCORE.

Bit 0 – URSTEN User Reset Enable

Value	Description
0	The detection of a low level on the NRST pin does not generate a user reset.
1	The detection of a low level on the NRST pin triggers a user reset.

24.5.4 RSTC Generic Reset Register

Name: RSTC_GRSTR
Offset: 0xE4
Reset: 0x00000070
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
		USB_RST3	USB_RST2	USB_RST1		DDR_PHY_RST		DDR_RST
Access		R/W	R/W	R/W		R/W		R/W
Reset		1	1	1		0		0

Bits 4, 5, 6 – USB_RSTx USB Reset
0 (POR_DISABLED): POR is disabled.
1 (POR_ENABLED): POR is enabled.

Bit 2 – DDR_PHY_RST DDR PHY Reset

Value	Description
0	DDR PHY reset is asserted.
1	DDR PHY reset is de-asserted.

Bit 0 – DDR_RST DDR Reset

Value	Description
0	DDR controller reset is asserted.
1	DDR controller reset is de-asserted.

25. Real-time Timer (RTT)

25.1 Description

The Real-time Timer (RTT) is built around a 32-bit counter used to count roll-over events of the programmable 16-bit prescaler driven from the 32-kHz slow clock source. It generates a periodic interrupt and/or triggers an alarm on a programmed value.

The RTT can also be configured to be driven by the 1Hz RTC signal, thus taking advantage of a calibrated 1Hz clock.

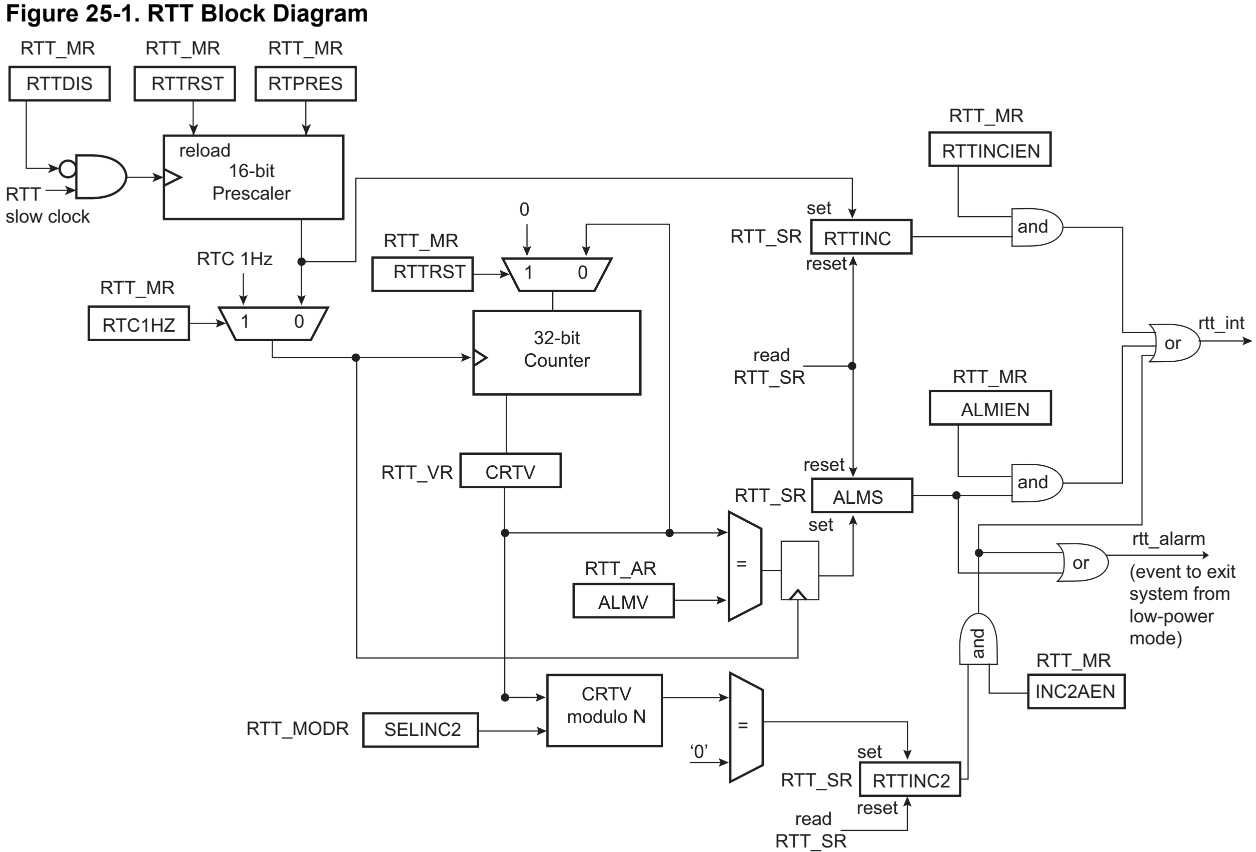
The slow clock source can be fully disabled to reduce power consumption when only an elapsed seconds count is required.

25.2 Embedded Characteristics

- 32-bit Free-running Counter on Prescaled Slow Clock or RTC Calibrated 1Hz Clock
- 16-bit Configurable Prescaler
- Interrupt on Alarm or Counter Increment
- Programmable Event

25.3 Block Diagram

Figure 25-1. RTT Block Diagram



25.4 Functional Description

The programmable 16-bit prescaler value can be configured through the RTPRES field in the RTT Mode register (RTT_MR).

Configuring RTPRES to 0x8000 (default value) corresponds to feeding the real-time counter with a 1Hz signal (if the slow clock is 32.768 kHz). The 32-bit counter can count up to 2^{32} seconds, corresponding to more than 136 years, then roll over to 0. Bit RTTINC in the RTT Status register (RTT_SR) is set each time there is a prescaler roll-over (see the figure below).

The real-time 32-bit counter can also be supplied by the 1Hz RTC clock. This mode is applicable when the RTC 1Hz is calibrated (RTC_MR.CORRECTION ≠ 0) in order to ensure the synchronism between RTC and RTT counters.

Setting RTT_MR.RTC1HZ drives the 32-bit RTT counter from the 1Hz RTC clock. In this mode, RTPRES has no effect on the 32-bit counter.

The prescaler roll-over generates an increment of the RTT counter if RTC1HZ = 0. Otherwise, if RTC1HZ = 1, the RTT counter is incremented every second. RTTINC is set independently from the 32-bit counter increment.

The RTT can also be used as a free-running timer with a lower time-base. The best accuracy is achieved by writing RTT_MR.RTPRES to 3.

Programming RTPRES to 1 or 2 is forbidden.

The CRTV field can be read at any time in the RTT Value register (RTT_VR). As this value can be updated asynchronously with the peripheral bus clock, CRTV must be read twice at the same value to read a correct value.

The current value of the counter is compared with the value written in the RTT Alarm register (RTT_AR). If the counter value matches the alarm, the ALMS bit in the RTT_SR is set. The RTT_AR is set to its maximum value (0xFFFFFFFF) after a reset.

ALMS is always a source of the RTT alarm signal that may be used to exit the system from low power modes (see the RTT Block Diagram above).

The alarm interrupt must be disabled (RTT_MR.ALMIEN must be cleared) when writing a new value to RTT_AR.ALMV.

RTT_SR.RTTINC can be used to start a periodic interrupt. The period is one second when RTT_MR.RTPRES = 0x8000 and the slow clock = 32.768 kHz.

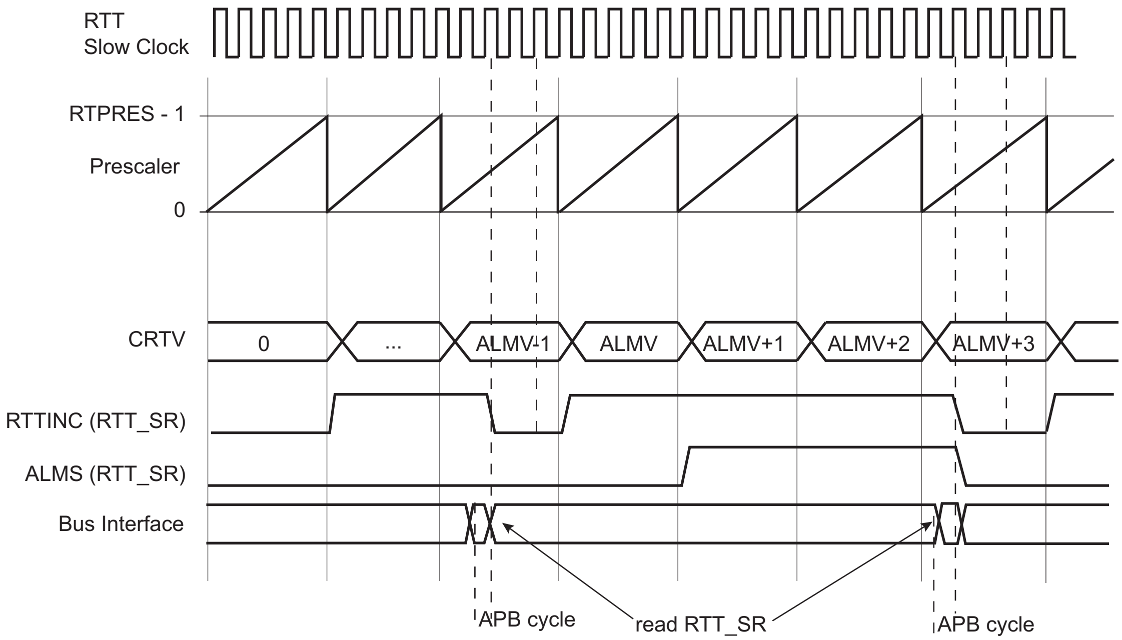
RTT_MR.RTTINCIEN must be cleared prior to writing a new value in RTT_MR. RTPRES.

Reading RTT_SR automatically clears RTT_SR.RTTINC and RTT_SR.ALMS.

Writing RTT_MR.RTTRST immediately reloads and restarts the clock divider with the new programmed value. This also resets the 32-bit counter.

When not used, the RTT can be disabled in order to suppress dynamic power consumption in this module. This can be achieved by setting RTT_MR.RTTDIS.

Figure 25-2. RTT Counting



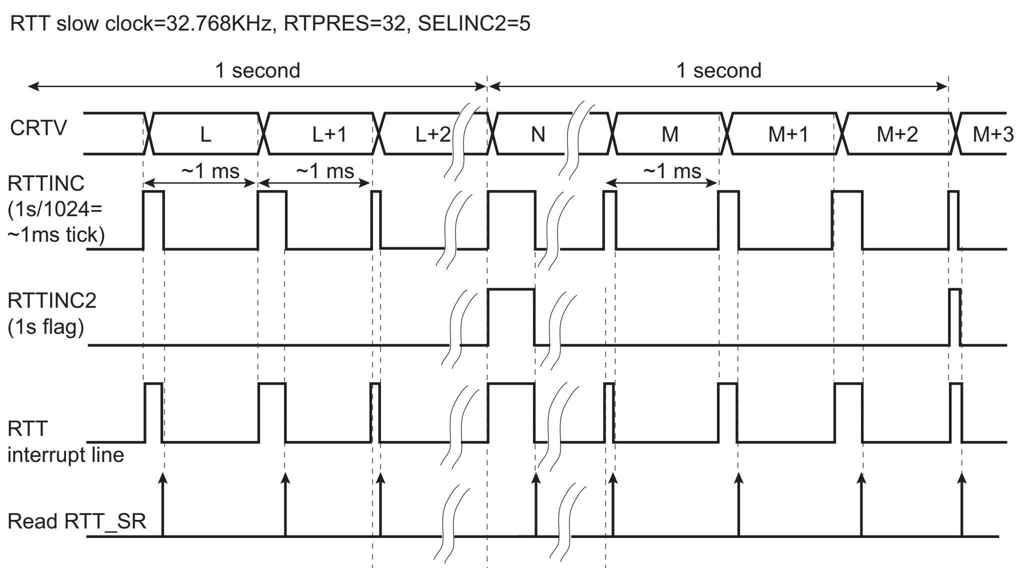
The RTTINC2 flag is set when the number of prescaler roll-overs programmed through the SELINC2 field in the RTT Modulo Selection register (RTT_MODR) has been reached since the last read of RTT_SR.

For example, it is possible to generate 2 sources of interrupt of different periods with flags RTTINC and RTTINC2. If the RTT slow clock frequency is 32.768 kHz and RTPRES=32, the RTTINC flag rises 1024 times per second (less than 1 ms period). If the field SELINC2=5, the RTTINC2 flag rises once per second.

If RTTINC is defined as the unique source of interrupt (RTTINCEN=1, ALMIEN=0 and INC2AEN=0 in RTT_MR), the value read in RTT_SR by the interrupt handler determines if the current interrupt event corresponds to a 1-second event (RTT_SR[2:1]=3) or to a 1-millisecond event (RTT_SR[2:1]=1). See the figure below.

If the bit INC2AEN=1, RTTINC2 flag is also a source for the RTT alarm signal. See RTT Block Diagram.

Figure 25-3. RTTINC2 Behavior



25.5 Register Summary

25.5.1 Real-time Timer Mode Register

Name: RTT_MR
Offset: 0x00
Reset: 0x00008000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode Register (SYSC_WPMR).

Bit	31	30	29	28	27	26	25	24
								RTC1HZ
Access								R/W
Reset								0

Bit	23	22	21	20	19	18	17	16
			INC2AEN	RTTDIS		RTTRST	RTTINCIEN	ALMIEN

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit 24 – RTC1HZ Real-Time Clock 1Hz Clock Selection

Value	Description
0	The RTT 32-bit counter is driven by the 16-bit prescaler roll-over events.
1	The RTT 32-bit counter is driven by the 1Hz RTC clock.

Bit 21 – INC2AEN RTTINC2 Alarm and Interrupt Enable

Value	Description
0	The RTTINC2 flag is not a source of the RTT alarm signal nor a source of interrupt.
1	The RTTINC2 flag is a source of the RTT alarm signal and a source of interrupt.

Bit 20 – RTTDIS Real-time Timer Disable

Value	Description
0	The RTT is enabled.
1	The RTT is disabled (no dynamic power consumption).

Bit 18 – RTTRST Real-time Timer Restart

Value	Description
0	No effect.
1	Reloads and restarts the clock divider with the new programmed value. This also resets the 32-bit counter.

Bit 17 – RTTINCIEN Real-time Timer Increment Interrupt Enable

Value	Description
0	The bit RTTINC in RTT_SR has no effect on interrupt.
1	The bit RTTINC in RTT_SR asserts interrupt.

Bit 16 – ALMIEN Alarm Interrupt Enable

Value	Description
0	The bit ALMS in RTT_SR has no effect on interrupt.
1	The bit ALMS in RTT_SR asserts interrupt.

Bits 15:0 – RTPRES[15:0] Real-time Timer Prescaler Value
Defines the number of RTT slow clock periods required to increment the Real-time timer. The RTTINCIEN bit must be cleared prior to writing a new RTPRES value.
RTPRES is defined as follows:

- RTPRES = 0: The prescaler period is equal to 2^{16} * slow clock periods.
- RTPRES = 1 or 2: forbidden.
- RTPRES ≠ 0, 1 or 2: The prescaler period is equal to RTPRES * slow clock periods.

25.5.2 Real-time Timer Alarm Register

Name: RTT_AR
Offset: 0x04
Reset: 0xFFFFFFFF
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode Register (SYSC_WPMR).

Bit	31	30	29	28	27	26	25	24
	ALMV[31:24]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	1	1	1	1	1	1	1	1

Bit	23	22	21	20	19	18	17	16
	ALMV[23:16]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	1	1	1	1	1	1	1	1

Bit	15	14	13	12	11	10	9	8
	ALMV[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	1	1	1	1	1	1	1	1

Bit	7	6	5	4	3	2	1	0
	ALMV[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	1	1	1	1	1	1	1	1

Bits 31:0 – ALMV[31:0] Alarm Value
When the CRTV value in RTT_VR equals the ALMV field, the ALMS flag is set in RTT_SR.
The alarm interrupt must be disabled (ALMIEN must be cleared in RTT_MR) when writing a new ALMV value.

25.5.3 Real-time Timer Value Register

Name: RTT_VR
Offset: 0x08
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
	CRTV[31:24]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	CRTV[23:16]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	CRTV[15:8]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	CRTV[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bits 31:0 – CRTV[31:0] Current Real-time Value
Returns the current value of the RTT.
As CRTV can be updated asynchronously, it must be read twice at the same value.

25.5.4 Real-time Timer Status Register

Name: RTT_SR
Offset: 0x0C
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
						RTTINC2	RTTINC	ALMS
Access						R	R	R
Reset						0	0	0

Bit 2 – RTTINC2 Predefined Number of Prescaler Roll-overs Status (cleared on read)

Value	Description
0	SELINC2 = 0 or the number of prescaler roll-overs programmed through the SELINC2 field in RTT_MODR has not been reached since the last read of the RTT_SR.
1	The number of prescaler roll-overs programmed through the SELINC2 field has been reached since the last read of the RTT_SR.

Bit 1 – RTTINC Prescaler Roll-over Status (cleared on read)

Value	Description
0	No prescaler roll-over occurred since the last read of the RTT_SR.
1	Prescaler roll-over occurred since the last read of the RTT_SR.

Bit 0 – ALMS Real-time Alarm Status (cleared on read)

Value	Description
0	The Real-time Alarm has not occurred since the last read of RTT_SR.
1	The Real-time Alarm occurred since the last read of RTT_SR.

25.5.5 Real-time Timer Modulo Selection Register

Name: RTT_MODR
Offset: 0x10
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode Register (SYSC_WPMR).

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
						SELINC2[2:0]		
Access						R/W	R/W	R/W
Reset						0	0	0

Bits 2:0 – SELINC2[2:0] Selection of the 32-bit Counter Modulo to generate RTTINC2 Flag

Value	Name	Description
0	NO_RTTINC2	The RTTINC2 flag never rises.
1	MOD64	The RTTINC2 flag is set when CRTV modulo 64 equals 0.
2	MOD128	The RTTINC2 flag is set when CRTV modulo 128 equals 0.
3	MOD256	The RTTINC2 flag is set when CRTV modulo 256 equals 0.
4	MOD512	The RTTINC2 flag is set when CRTV modulo 512 equals 0.
5	MOD1024	The RTTINC2 flag is set when CRTV modulo 1024 equals 0. Example: If RTPRES=32 then RTTINC2 flag rises once per second if the slow clock is 32.768 kHz.
6	MOD2048	The RTTINC2 flag is set when CRTV modulo 2048 equals 0.
7	MOD4096	The RTTINC2 flag is set when CRTV modulo 4096 equals 0.

25.5.6 Real-time Timer Timestamp Register

Name: RTT_TSR
Offset: 0x14
Reset: 0x00000000

Bits 23:0 – TSTAMP[23:0] Real-time Timer Value Timestamp
Each time an event triggers the flag RTT_SR.RTTINC2, RTT_VR.CRTV is copied into RTT_TSR.TSTAMP. The field TSTAMP remains stable until next event RTT_SR.RTTINC2 and can be used for event timestamping.

26. Real-time Clock (RTC)

26.1 Description

The Real-time Clock (RTC) peripheral is designed for very low power consumption. For optimal functionality, the RTC requires an accurate external 32.768 kHz clock, which can be provided by a crystal oscillator.

It combines a complete time-of-day clock with alarm and a Gregorian or Persian calendar, complemented by a programmable periodic interrupt. The alarm and calendar registers are accessed by a 32-bit data bus.

The RTC can also be configured for the UTC time format.

The time and calendar values are coded in binary-coded decimal (BCD) format. The time format can be 24-hour mode or 12-hour mode with an AM/PM indicator.

Updating time and calendar fields and configuring the alarm fields are performed by a parallel capture on the 32-bit data bus. An entry control is performed to avoid loading registers with incompatible BCD format data or with an incompatible date according to the current month/year/century.

A clock divider calibration circuitry can be used to compensate for crystal oscillator frequency variations.

An RTC output can be programmed to generate several waveforms, including a prescaled clock derived from 32.768 kHz.

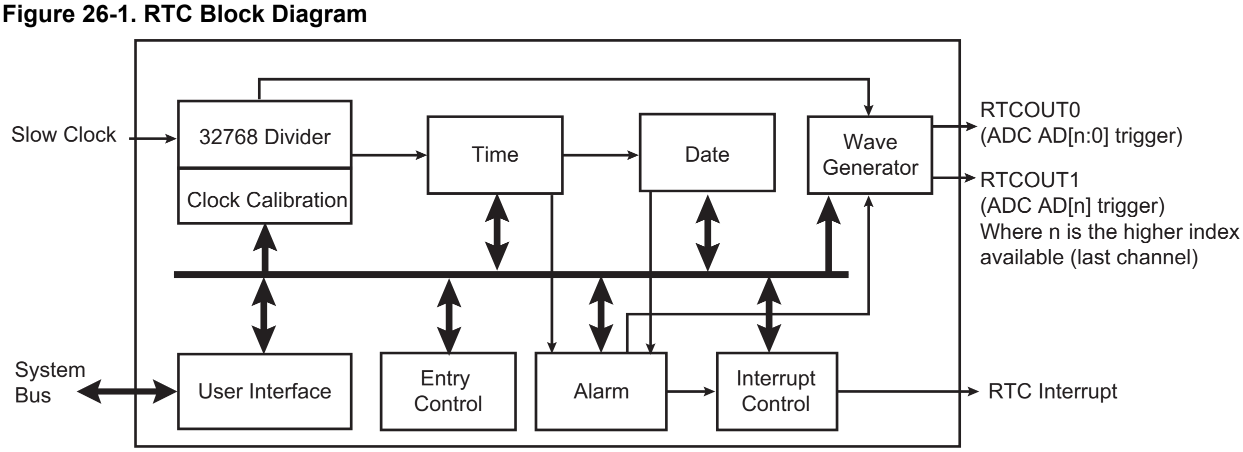
Timestamping capability reports the first and last occurrences of tamper events.

26.2 Embedded Characteristics

- Full Asynchronous Design for Ultra Low-Power Consumption
- Gregorian, UTC and Persian Modes Supported
- Programmable Periodic Interrupt
- Safety/Security Features:
  - Valid time and date programming check
  - On-the-fly time and date validity check
- Counters Calibration Circuitry to Compensate for Crystal Oscillator Variations
- Waveform Generation for ADC Trigger Event
- Tamper Timestamping Registers
- Register Write Protection

26.3 Block Diagram

Figure 26-1. RTC Block Diagram



26.4 Product Dependencies

26.4.1 Power Management

The Real-time Clock is continuously clocked at 32.768 kHz. The Power Management Controller (PMC) has no effect on RTC behavior.

26.4.2 Interrupt

Within the System Controller, the RTC interrupt is OR-wired with all the other module interrupts.

Only one System Controller interrupt line is connected on one of the internal sources of the interrupt controller.

RTC interrupt requires the interrupt controller to be programmed first.

When a System Controller interrupt occurs, the service routine must first determine the cause of the interrupt. This is done by reading each status register of the System Controller peripherals successively.

26.5 Functional Description

The RTC provides a full binary-coded decimal (BCD) clock that includes century (19/20), year (with leap years), month, date, day, hours, minutes and seconds reported in RTC Time Register (RTC_TIMR) and RTC Calendar Register (RTC_CALR).

The RTC can operate in UTC mode, giving the number of seconds elapsed since a reference time defined by the user (the UTC standard—ISO 8601—reference time is the 30th of June 1972). In this mode, the timefield is 32 bits wide and coded in hexadecimal format.

The valid year range is up to 2099 in Gregorian mode (or 1300 to 1499 in Persian mode).

The RTC can operate in 24-hour mode or in 12-hour mode with an AM/PM indicator.

Corrections for leap years are included (all years divisible by 4 being leap years except 1900). This is correct up to the year 2099.

The RTC can generate configurable waveforms on RTCOUT0/1 outputs.

26.5.1 Reference Clock

The reference clock is the slow clock. It can be driven externally by a 32.768 kHz crystal, or internally.

26.5.2 Timing

In Gregorian and Persian modes, the RTC is updated in real time at one-second intervals in Normal mode for the counters of seconds, at one-minute intervals for the counter of minutes and so on.

In UTC mode, the RTC is updated in real-time at one-second intervals (32-bit UTC counter default configuration).

Due to the asynchronous operation of the RTC with respect to the rest of the chip, to ensure that the value read in the RTC registers (century, year, month, date, day, hours, minutes, seconds) are valid and stable, it is necessary to read these registers twice. If the data is the same both times, then it is valid. Therefore, a minimum of two and a maximum of three accesses are required.

26.5.3 Alarm

In Gregorian and Persian modes, the RTC has five programmable fields: month, date, hours, minutes and seconds.

Each of these fields can be enabled or disabled to match the alarm condition:

- If all the fields are enabled, an alarm flag is generated (the corresponding flag is asserted and an interrupt generated if enabled) at a given month, date, hour/minute/second.
- If only the “seconds” field is enabled, then an alarm is generated every minute.

Depending on the fields that are enabled in the RTC Calendar Alarm register (RTC_CALALR) and the RTC Time Alarm register(RTC_TIMALR), a large number of possibilities are available to the user ranging from minutes to 365/366 days.

Note: To change one of the RTC_TIMALR.SEC, MIN, HOUR and/or RTC_CALALR.DATE, MONTH fields, it is recommended to disable the field before changing the value and then re-enable it after the change has been made. This requires up to three accesses to the RTC_TIMALR or RTC_CALALR. The first access clears the enable corresponding to the field to change (RTC_TIMALR.SECEN, MINEN, HOUREN and/or RTC_CALALR.DATEEN, MTHEN). If the field is already cleared, this access is not required. The second access performs the change of the value (RTC_TIMALR.SEC, MIN, HOUR and/or RTC_CALALR.DATE, MONTH). The third access is required to re-enable the field by writing 1 in RTC_TIMALR.SECEN, MINEN, HOUREN and/or RTC_CALALR.DATEEN, MTHEN.

In UTC mode, RTC_TIMALR must be configured to set the UTC alarm value and bit 0 in RTC_CALALR must be used to enable or disable the UTC alarm. If the UTC alarm is enabled, the alarm is generated once the UTC time matches the programmed UTC_TIME alarm field.

To change the UTC_TIME alarm field, proceed as follows:

1. Disable the UTC alarm by clearing RTC_CALALR.UTCEN if it is not already cleared.
2. Change the RTC_TIMALR.UTC_TIME alarm value.
3. Re-enable the UTC alarm by setting RTC_CALALR.UTCEN.

26.5.4 Error Checking when Programming

Verification on user interface data is performed when accessing the century, year, month, date, day, hours, minutes, seconds and alarms. A check is performed on illegal BCD entries such as illegal date of the month with regard to the year and century configured.

If one of the time fields is not correct, the data is not loaded into the register/counter and a flag is set in the validity register. The user can not reset this flag. It is reset as soon as an acceptable value is programmed. This avoids any further side effects in the hardware. The same procedure is followed for the alarm.

The following checks are performed:

1. Century (check if it is in range 19–20 or 13–14 in Persian mode)
2. Year (BCD entry check)
3. Date (check range 01–31)
4. Month (check if it is in BCD range 01–12, check validity regarding “date”)
5. Day (check range 1–7)
6. Hour (BCD checks: in 24-hour mode, check range 00–23 and check that AM/PM flag is not set if RTC is set in 24-hour mode; in 12-hour mode check range 01–12)
7. Minute (check BCD and range 00–59)
8. Second (check BCD and range 00–59)

Notes:

1. If the 12-hour mode is selected by means of the Mode register (RTC_MR), a 12-hour value can be programmed and the returned value on RTC_TIMR will be the corresponding 24-hour value. The entry control checks the value of the AM/PM indicator (bit 22 of RTC_TIMR) to determine the range to be checked.
2. In UTC mode, no check is performed on the entries. The RTC does not report any failure.

26.5.5 RTC Internal Free-Running Counter Error Checking

To improve the reliability and security of the RTC, a permanent check is performed on the internal free-running counters to report non-BCD or invalid date/time values.

An error is reported by RTC_SR.TDERR if an incorrect value has been detected. The flag can be cleared by setting the RTC_SCCR.TDERRCLR.

In all cases, RTC_SR.TDERR is set again if the source of the error has not been cleared before clearing RTC_SR.TDERR. The clearing of the source of such error can be done by reprogramming a correct value on RTC_CALR and/or RTC_TIMR.

The RTC internal free-running counters may automatically clear the source of RTC_SR.TDERR due to their roll-over (i.e., every 10 seconds for SECONDS[3:0] in RTC_TIMR). In this case, RTC_SR.TDERR is held high until a clear command is asserted by writing a 1 in RTC_SCCR.TDERRCLR.

26.5.6 Updating Time/Calendar

26.5.6.1 Gregorian and Persian Modes

To update time and date, the RTC must be stopped by setting the corresponding field in the Control register (RTC_CR). RTC_CR.UPDTIM must be set to update time fields (hour, minute, second) and RTC_CR.UPDCAL must be set to update calendar fields (century, year, month, date, day).

RTC_SR.ACKUPD must then be read to 1 by either polling RTC_SR or by enabling the acknowledge update interrupt by writing RTC_IER.ACKUPD to '1'. Once RTC_SR.ACKUPD is read to 1, it is mandatory to clear this flag by writing a 1 in RTC_SCCR.ACKCLR, after which the user can write to the Time register (RTC_TIMR), the Calendar register (RTC_CALR), or both.

Once the update is finished, the user must write a '0' in RTC_CR.UPDTIM and/or RTC_CR.UPDCAL.

The timing sequence of the time/calendar update is described in the figure below.

When entering the Programming mode of the calendar fields, the time fields remain enabled. When entering the Programming mode of the time fields, both the time and the calendar fields are stopped. This is due to the location of the calendar logical circuitry (downstream for low-power considerations).

In successive update operations, the user must first check that RTC_CR.UPDTIM and RTC_CR.UPDCAL read 0 before writing these bits to '1'.

Figure 26-2. Time/Calendar Update Timing Diagram

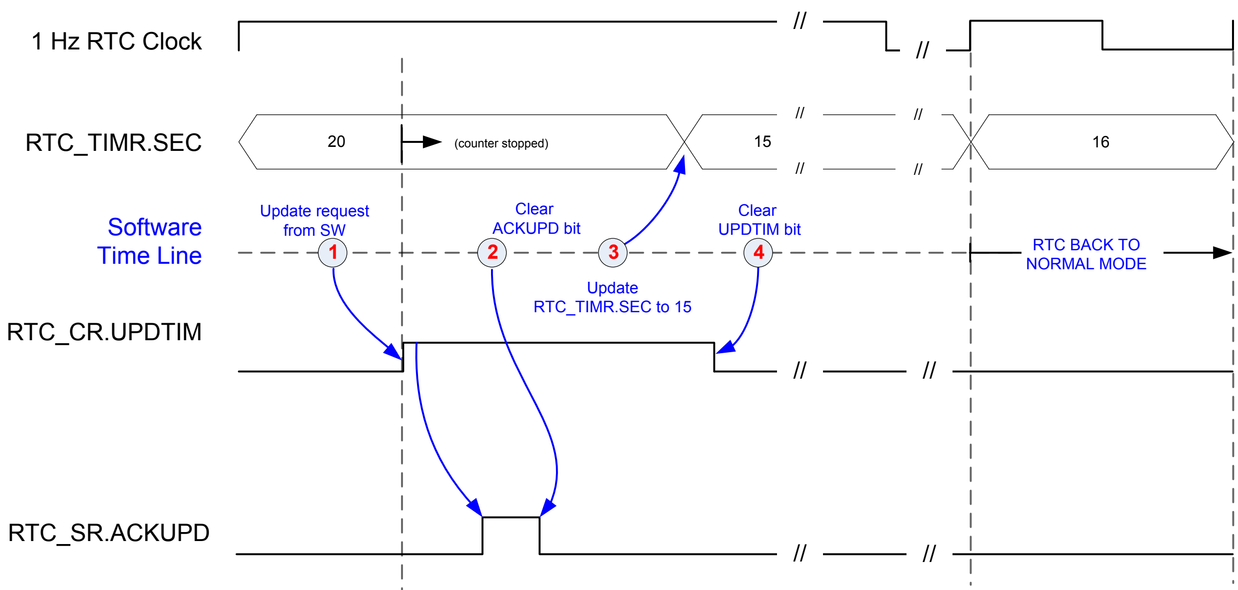


Figure 26-3. Gregorian and Persian Modes Update Sequence

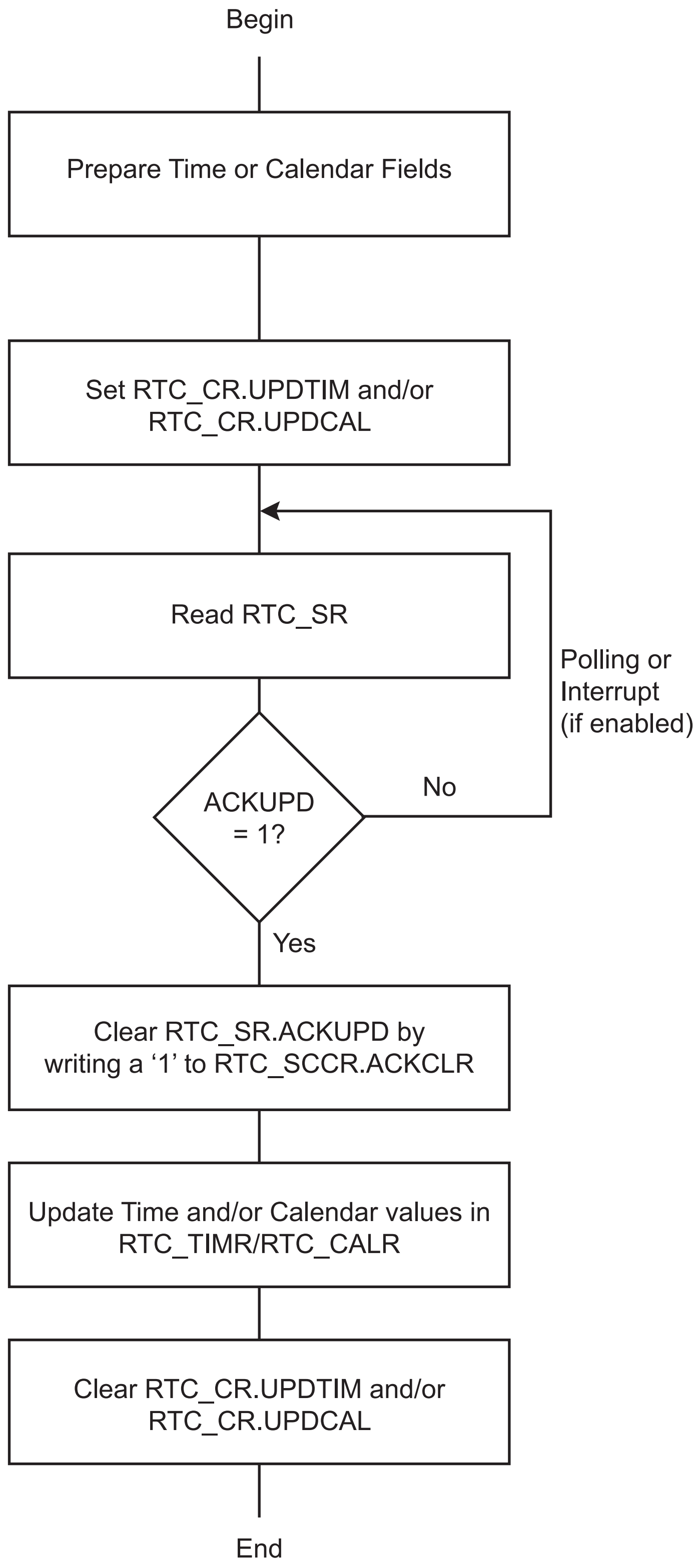

26.5.6.2 UTC Mode

To update the UTC time, the RTC must be stopped by writing a 1 in RTC_CR.UPDTIM and RTC_CR.UPDCAL.

RTC_SR.ACKUPD must then be read to 1 by either polling RTC_SR or by enabling the acknowledge update interrupt by writing a 1 in RTC_IER.ACKUP. Once RTC_SR.ACKUPD is read to 1, it is mandatory to clear this flag by writing a 1 in RTC_SCCR.ACKCLR, after which the user can write to RTC_TIMR.

Once the update is finished, the user must write a 0 in RTC_CR.UPDTIM and a 0 in RTC_CR.UPCAL.

In successive update operations, the user must first check that RTC_CR.UPDTIM and RTC_CR.UPDCAL read 0 before writing a 1 in these bits.

The timing sequence of the UTC time update is described in the figure below.

Figure 26-4. UTC Time Update Timing Diagram

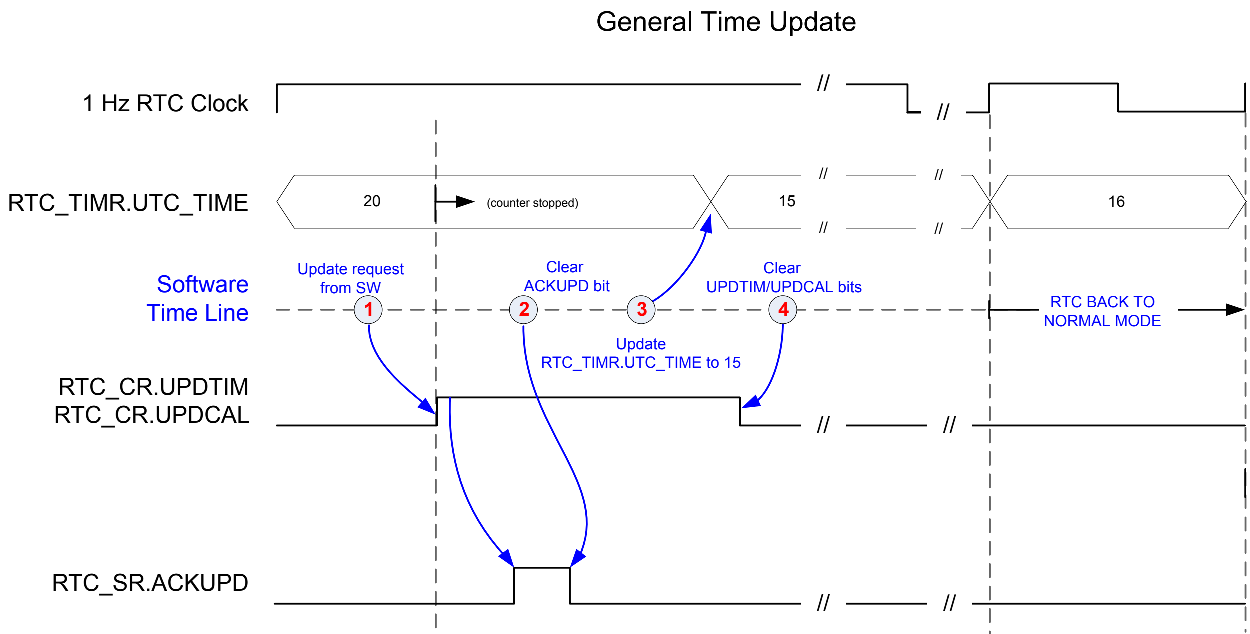

Figure 26-5. UTC Mode Update Sequence

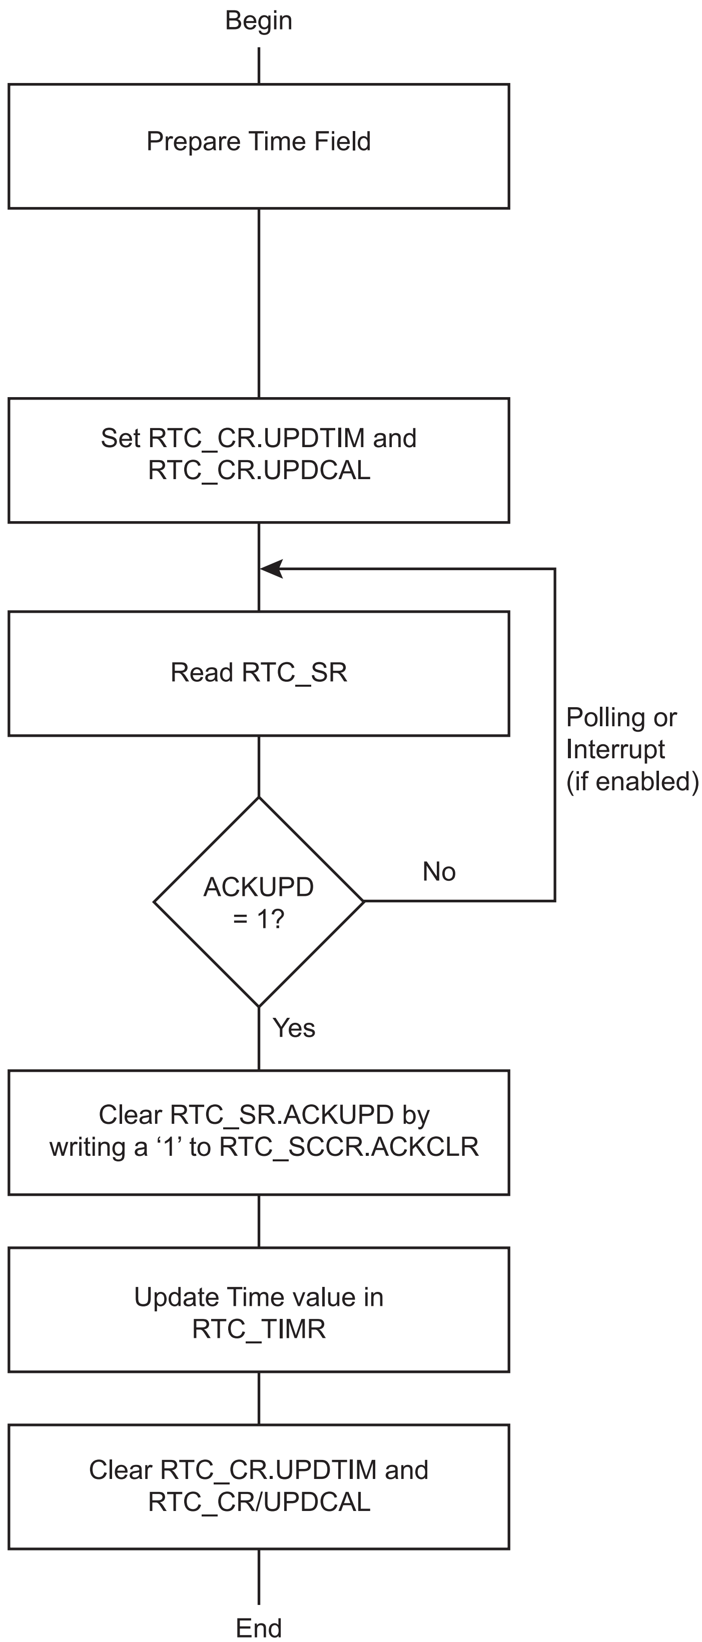

26.5.7 RTC Accurate Clock Calibration

The crystal oscillator that drives the RTC may not be as accurate as expected mainly due to temperature variation. The RTC is equipped with circuitry able to correct slow clock crystal drift.

To compensate for possible temperature variations over time, this accurate clock calibration circuitry can be programmed on-the-fly and also programmed during application manufacturing, in order to correct the crystal frequency accuracy at room temperature (20–25°C). The typical clock drift range at room temperature is ±20 ppm.

In the device operating temperature range, the 32.768 kHz crystal oscillator clock inaccuracy can be up to -200 ppm.

The RTC clock calibration circuitry allows positive or negative correction in a range of 1.5 ppm to 1950 ppm.

The calibration circuitry is fully digital. Thus, the configured correction is independent of temperature, voltage, process, etc., and no additional measurement is required to check that the correction is effective.

If the correction value configured in the calibration circuitry results from an accurate crystal frequency measure, the remaining accuracy is bounded by the values listed below:

- Below 1 ppm, for an initial crystal drift between 1.5 ppm up to 20 ppm, and from 30 ppm to 90 ppm
- Below 2 ppm, for an initial crystal drift between 20 ppm up to 30 ppm, and from 90 ppm to 130 ppm
- Below 5 ppm, for an initial crystal drift between 130 ppm up to 200 ppm

The calibration circuitry does not modify the 32.768 kHz crystal oscillator clock frequency but it acts by slightly modifying the 1 Hz clock period from time to time. The correction event occurs every 1 + [(20 - (19 x HIGHPPM)) x CORRECTION] seconds. When the period is modified, depending on the sign of the correction, the 1 Hz clock period increases or reduces by around 4 ms. Depending on the CORRECTION, NEGPPM and HIGHPPM values configured in RTC_MR, the period interval between two correction events differs.

Figure 26-6. Calibration Circuitry

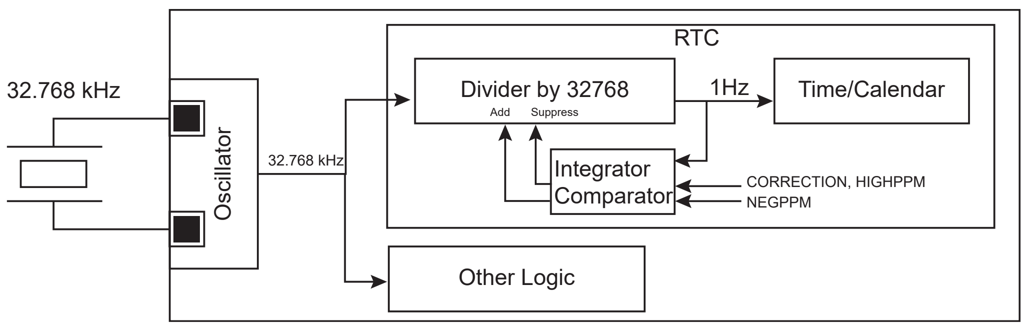

Figure 26-7. Calibration Circuitry Waveforms

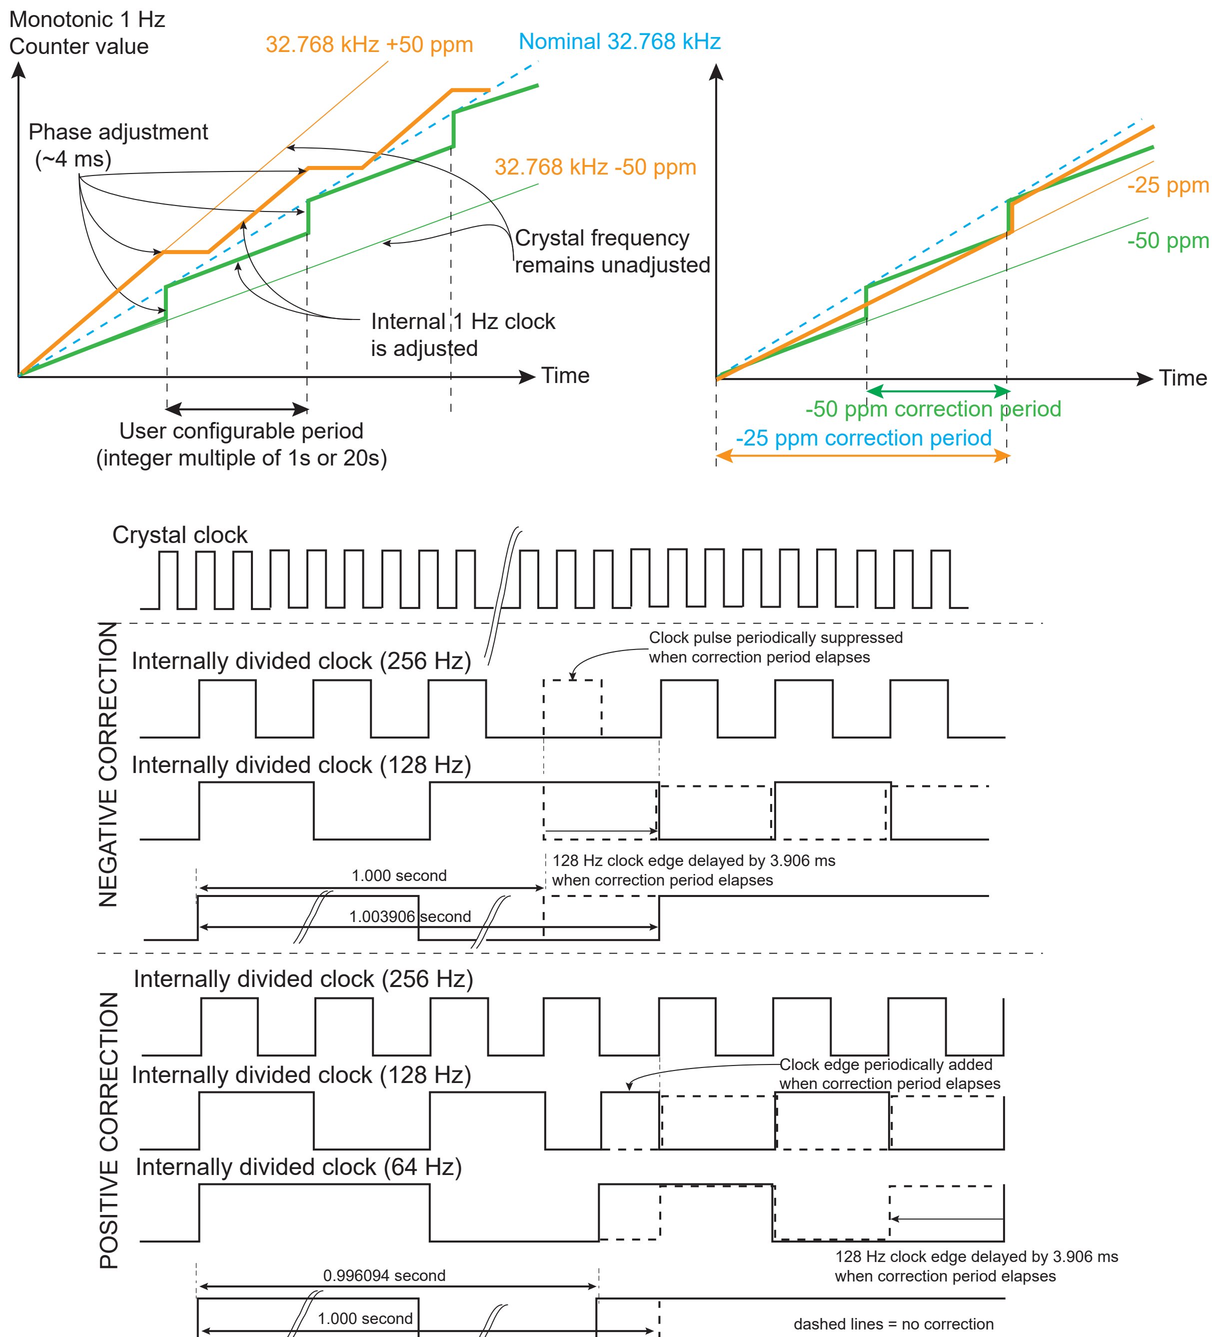


The inaccuracy of a crystal oscillator at typical room temperature (±20 ppm at 20–25 °C) can be compensated if a reference clock/signal is used to measure such inaccuracy. This kind of calibration operation can be set up during the final product manufacturing by means of measurement equipment embedding such a reference clock. The correction of value must be programmed into RTC_MR, and this value is kept as long as the circuitry is powered (backup area). Removing the backup power supply cancels this calibration. This room temperature calibration can be further processed by means of the networking capability of the target application.

To ease the comparison of the inherent crystal accuracy with the reference clock/signal during manufacturing, an internal prescaled 32.768 kHz clock derivative signal can be assigned to drive RTC output. To accommodate the measure, several clock frequencies can be selected among 1 Hz, 32 Hz, 64 Hz, 512 Hz.

The clock calibration correction drives the internal RTC counters but can also be observed in the RTC output when one of the following three frequencies 1 Hz, 32 Hz or 64 Hz is configured. The correction is not visible in the RTC output if 512 Hz frequency is configured.

Note that this adjustment does not take into account the temperature variation.

The frequency drift (up to -200 ppm) due to temperature variation can be compensated using a reference time if the application can access such a reference. If a reference time cannot be used, a temperature sensor can be placed close to the crystal oscillator in order to get the operating temperature of the crystal oscillator. Once obtained, the temperature may be converted using a lookup table (describing the accuracy/temperature curve of the crystal oscillator used) and RTC_MR configured accordingly. The calibration can be performed on-the-fly. This adjustment method is not based on a measurement of the crystal frequency/drift and therefore can be improved by means of the networking capability of the target application.

If no crystal frequency adjustment has been done during manufacturing, it is still possible to make adjustments. In the case where a reference time of the day can be obtained through a LAN/WAN network, it is possible to calculate the drift of the application crystal oscillator by comparing the values read on RTC_TIMR and RTC_CALR and programming RTC_MR.HIGHPPM and RTC_MR.CORRECTION according to the difference measured between the reference time and those of RTC_TIMR and RTC_CALR.

26.5.8 Waveform Generation

Waveforms can be generated in order to take advantage of the RTC inherent prescalers while the RTC is the only powered circuitry (Low-power mode of operation, Backup mode) or in any active mode. Entering Backup or Low-power operating modes does not affect the waveform generation outputs.

The outputs RTCOUT0 and RTCOUT1 can be configured to provide several types of waveforms. The figure below illustrates the different signals available to generate RTCOUT0 and RTCOUT1.

The RTC waveforms are internally routed to ADC trigger events. These events can be configured to provide several types of waveforms. The figure below illustrates the different signals available to generate the waveforms. Two different triggers can be generated at a time. The first is configured in RTC_MR.OUT0 while the second is configurable in RTC_MR.OUT1. OUT0 manages the trigger for channel AD[n:0] (where n is the higher index available (last channel)), while OUT1 manages the channel AD[n] only for specific modes. See the section "Analog to Digital Converter (ADC)" for selection of the measurement triggers and associated modes of operation.

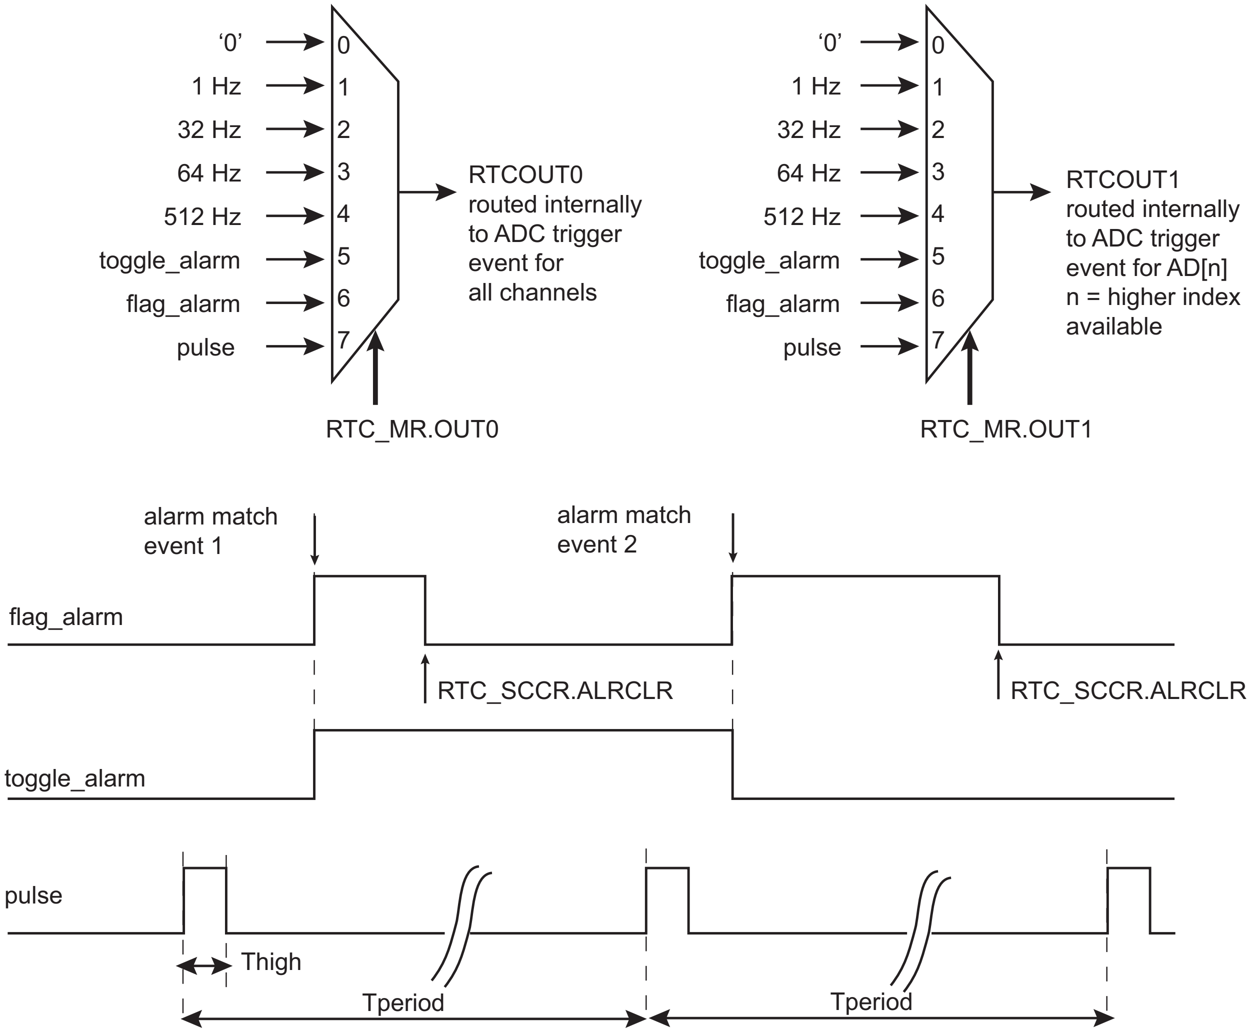
The first selection choice sticks the associated output at 0. (This is the reset value and it can be used at any time to disable the waveform generation).

Selection choices 1 to 4 respectively select 1 Hz, 32 Hz, 64 Hz and 512 Hz.

Selection choice 5 provides a toggling signal when the RTC alarm is reached.

Selection choice 6 provides a copy of the alarm flag, so the associated output is set high (logical 1) when an alarm occurs and immediately cleared when software clears the alarm interrupt source.

Figure 26-8. Waveform Generation



26.5.9 Tamper Timestamping

As soon as a tamper is detected, the tamper counter is incremented and the RTC stores the time of the day, the date and the source of the tamper event in registers located in the backup area. Up to two tamper events can be stored.

In UTC mode, only the UTC time is stored. The date information is not relevant.

The tamper counter saturates at 15. Once this limit is reached, the exact number of tamper occurrences since the last read of stamping registers cannot be known.

The first set of timestamping registers (RTC_TSTR0, RTC_TSDR0, RTC_TSSR0) cannot be overwritten. Once they have been written, all data are stored until the registers are reset. Thus these registers store the first tamper occurrence after a read.

The second set of timestamping registers (RTC_TSTR1, RTC_TSDR1, RTC_TSSR1) are overwritten each time a tamper event is detected. Thus the date and the time data of the first and the second stamping registers may be equal. This occurs when the tamper counter value carried on RTC_TSTR0.TEVCNT equals 1. Thus this second set of registers stores the last occurrence of tamper before a read.

Reading a set of timestamping registers requires three accesses, one for the time of the day, one for the date and one for the tamper source.

Reading the third part (RTC_TSSR0/1) of a timestamping register set clears the whole content of the registers (time, date and tamper source) and makes the timestamping registers available to store a new event.

26.6 Register Summary

26.6.1 RTC Control Register

Name: RTC_CR
Offset: 0x00
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode register (SYSC_WPMR).

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
							CALEVSEL[1:0]	
Access							R/W	R/W
Reset							0	0

Bit	15	14	13	12	11	10	9	8
							TIMEVSEL[1:0]	
Access							R/W	R/W
Reset							0	0

Bit	7	6	5	4	3	2	1	0
							UPDCAL	UPDTIM
Access							R/W	R/W
Reset							0	0

Bits 17:16 – CALEVSEL[1:0] Calendar Event Selection
The event that generates the flag CALEV in RTC_SR depends on the value of CALEVSEL
In UTC mode, this field has no effect on RTC_SR.

Value	Name	Description
0	WEEK	Week change (every Monday at time 00:00:00)
1	MONTH	Month change (every 01 of each month at time 00:00:00)
2	YEAR	Year change (every January 1 at time 00:00:00)
3	YEAR	Reserved

Bits 9:8 – TIMEVSEL[1:0] Time Event Selection
The event that generates the flag TIMEV in RTC_SR depends on the value of TIMEVSEL.
In UTC mode, this field has no effect on RTC_SR.

Value	Name	Description
0	MINUTE	Minute change
1	HOUR	Hour change
2	MIDNIGHT	Every day at midnight
3	NOON	Every day at noon

Bit 1 – UPDCAL Update Request Calendar Register
Calendar counting consists of day, date, month, year and century counters. Calendar counters can be programmed once this bit is set and acknowledged by the RTC_SR.ACKUPD bit.
In UTC mode, both UPDTIM and UPDCAL must be set to '1' in order to update the UTC time value.

Value	Name	Description
0	CLOSE_UPDATE	No effect or, if UPDCAL has been previously written to 1, stops the update procedure.
1	START_UPDATE	Stops the RTC calendar counting.

Bit 0 – UPDTIM Update Request Time Register

Time counting consists of second, minute and hour counters. Time counters can be programmed once this bit is set and acknowledged by the RTC_SR.ACKUPD bit.

In UTC mode, both UPDTIM and UPDCAL must be set to '1' in order to update the UTC time value.

Value	Name	Description
0	CLOSE_UPDATE	No effect or, if UPDTIM has been previously written to 1, stops the update procedure.
1	STARTE_UPDATE	Stops the RTC time counting.

26.6.2 RTC Mode Register

Name: RTC_MR
Offset: 0x04
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode register (SYSC_WPMR).

Bit	31	30	29	28	27	26	25	24
			TPERIOD[1:0]			THIGH[2:0]		
Access			R/W	R/W		R/W	R/W	R/W

	HIGHPPM	CORRECTION[6:0]						
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
				NEGPPM		UTC	PERSIAN	HRMOD
Access				R/W		R/W	R/W	R/W
Reset				0		0	0	0

Bits 29:28 – TPERIOD[1:0] Period of the Output Pulse

Value	Name	Description
0	P_1S	1 second
1	P_500MS	500 ms
2	P_250MS	250 ms
3	P_125MS	125 ms

Bits 26:24 – THIGH[2:0] High Duration of the Output Pulse

Value	Name	Description
0	H_31MS	31.2 ms
1	H_16MS	15.6 ms
2	H_4MS	3.91 ms
3	H_976US	976 μs
4	H_488US	488 μs
5	H_122US	122 μs
6	H_30US	30.5 μs
7	H_15US	15.2 μs

Bits 22:20 – OUT1[2:0] RTCOUT1 Output and ADC Last Channel Trigger Event Source Selection

Value	Name	Description
0	NO_WAVE	No waveform, stuck at ‘0’
1	FREQ1HZ	1 Hz square wave
2	FREQ32HZ	32 Hz square wave
3	FREQ64HZ	64 Hz square wave
4	FREQ512HZ	512 Hz square wave
5	ALARM_TOGGLE	Output toggles when alarm flag rises

Value	Name	Description
6	ALARM_FLAG	Output is a copy of the alarm flag
7	PROG_PULSE	Duty cycle programmable pulse

Bits 18:16 – OUT0[2:0] RTCOUT0 Output and All ADC Channel Trigger Event Source Selection

Value	Name	Description
0	NO_WAVE	No waveform, stuck at ‘0’
1	FREQ1HZ	1 Hz square wave
2	FREQ32HZ	32 Hz square wave
3	FREQ64HZ	64 Hz square wave
4	FREQ512HZ	512 Hz square wave
5	ALARM_TOGGLE	Output toggles when alarm flag rises
6	ALARM_FLAG	Output is a copy of the alarm flag
7	PROG_PULSE	Duty cycle programmable pulse

Bit 15 – HIGHPPM HIGH PPM Correction
If the absolute value of the correction to be applied is lower than 30 ppm, it is recommended to clear HIGHPPM. HIGHPPM set to 1 is recommended for 30 ppm correction and above.
Formula:
If HIGHPPM = 0, then the clock frequency correction range is from 1.5 ppm up to 98 ppm. The RTC accuracy is less than 1 ppm for a range correction from 1.5 ppm up to 30 ppm.
The correction field must be programmed according to the required correction in ppm; the formula is as follows:

$$\mathrm{CORRECTION} = \frac{3906}{20 \times \mathrm{ppm}} - 1$$

The value obtained must be rounded to the nearest integer prior to being programmed into CORRECTION field.
If HIGHPPM = 1, then the clock frequency correction range is from 30.5 ppm up to 1950 ppm. The RTC accuracy is less than 1 ppm for a range correction from 30.5 ppm up to 90 ppm.
The correction field must be programmed according to the required correction in ppm; the formula is as follows:

$$\mathrm{CORRECTION} = \frac{3906}{\mathrm{ppm}} - 1$$

The value obtained must be rounded to the nearest integer prior to be programmed into CORRECTION field.
If NEGPPM is set to 1, the ppm correction is negative (used to correct crystals that are faster than the nominal 32.768 kHz).

Value	Name	Description
0	DISABLED	Lower range ppm correction with accurate correction (below 30ppm correction).
1	ENABLED	Higher range ppm correction with accurate correction (higher than 30ppm correction).

Bits 14:8 – CORRECTION[6:0] Slow Clock Correction

Value	Name	Description
0	DISABLED	No correction
1–127	–	The slow clock will be corrected according to the formula given in HIGHPPM description.

Bit 4 – NEGPPM Negative PPM Correction
See CORRECTION and HIGHPPM field descriptions.
NEGPPM must be cleared to correct a crystal slower than 32.768 kHz.

Value	Name	Description
0	DISABLED	Positive correction (the divider will be slightly higher than 32768).
1	ENABLED	Negative correction (the divider will be slightly lower than 32768).

Bit 2 – UTC UTC Time Format
It is forbidden to write a one to the UTC and PERSIAN bits at the same time.

Value	Name	Description
0	DISABLED	Gregorian or Persian calendar.
1	ENABLED	UTC format.

Bit 1 – PERSIAN PERSIAN Calendar

Value	Name	Description
0	DISABLED	Gregorian calendar.
1	ENABLED	Persian calendar.

Bit 0 – HRMOD 12-/24-hour Mode

Value	Name	Description
0	24HOURS	24-hour mode is selected.
1	AMPM	12-hour mode is selected.

26.6.3 RTC Time Register

Name: RTC_TIMR
Offset: 0x08
Reset: 0x00000000
Property: Read/Write

In UTC mode, this register view is not relevant, see 26.6.7. RTC_TIMALR (UTC_MODE) .

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode register (SYSC_WPMR).

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
		AMPM	HOUR[5:0]					
Access		R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset		0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
		MIN[6:0]						
Access		R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset		0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
		SEC[6:0]						
Access		R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset		0	0	0	0	0	0	0

Bit 22 – AMPM Ante Meridiem Post Meridiem Indicator
This bit is the AM/PM indicator in 12-hour mode.

Value	Description
0	AM.
1	PM.

Bits 21:16 – HOUR[5:0] Current Hour
The range that can be set is 1–12 (BCD) in 12-hour mode or 0–23 (BCD) in 24-hour mode.

Bits 14:8 – MIN[6:0] Current Minute
The range that can be set is 0–59 (BCD).
The lowest four bits encode the units. The higher bits encode the tens.

Bits 6:0 – SEC[6:0] Current Second
The range that can be set is 0–59 (BCD).
The lowest four bits encode the units. The higher bits encode the tens.

26.6.4 RTC Time Register (UTC_MODE)

Name: RTC_TIMR (UTC_MODE)
Offset: 0x08
Reset: 0x00000000
Property: Read/Write

This configuration is relevant only if UTC = 1 in RTC_MR.

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode register (SYSC_WPMR).

Bit	31	30	29	28	27	26	25	24
	UTC_TIME[31:24]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0
Bit	23	22	21	20	19	18	17	16
	UTC_TIME[23:16]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8
	UTC_TIME[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
	UTC_TIME[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 31:0 – UTC_TIME[31:0] Current UTC Time
Any value can be set.

26.6.5 RTC Calendar Register

Name: RTC_CALR
Offset: 0x0C
Reset: 0x01E11220
Property: Read/Write

In UTC mode, values read in this register are not relevant.

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode register (SYSC_WPMR).

Bit	31	30	29	28	27	26	25	24
			DATE[5:0]					
Access			R/W	R/W	R/W	R/W	R/W	R/W
Reset								

Bit	23	22	21	20	19	18	17	16
	DAY[2:0]			MONTH[4:0]				
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset								

Bit	15	14	13	12	11	10	9	8
	YEAR[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset								

Bit	7	6	5	4	3	2	1	0
		CENT[6:0]						
Access		R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset								

Bits 29:24 – DATE[5:0] Current Day in Current Month
The range that can be set is 01–31 (BCD).
The lowest four bits encode the units. The higher bits encode the tens.

Bits 23:21 – DAY[2:0] Current Day in Current Week
The range that can be set is 1–7 (BCD).
The coding of the number (which number represents which day) is user-defined as it has no effect on the date counter.

Bits 20:16 – MONTH[4:0] Current Month
The range that can be set is 01–12 (BCD).
The lowest four bits encode the units. The higher bits encode the tens.

Bits 15:8 – YEAR[7:0] Current Year
The range that can be set is 00–99 (BCD).
The lowest four bits encode the units. The higher bits encode the tens.

Bits 6:0 – CENT[6:0] Current Century
The range that can be set is 20 (Gregorian) or 13–14 (Persian) (BCD).
The lowest four bits encode the units. The higher bits encode the tens.
Note: Value 20 (BCD) is always written in CENT whatever the value entered, thus there is no trigger event on RTC_VER.NVCAL regarding CENT.

26.6.6 RTC Time Alarm Register

Name: RTC_TIMALR
Offset: 0x10
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode register (SYSC_WPMR).

To change one of the SEC, MIN, HOUR fields, it is recommended to disable the field before changing the value and then re-enable it after the change has been made. This requires up to three accesses to RTC_TIMALR. The first access clears the enable corresponding to the field to change (SECEN, MINEN, HOUREN). If the field is already cleared, this access is not required. The second access performs the change of value (SEC, MIN, HOUR). The third access is required to re-enable the field by writing 1 in the SECEN, MINEN, HOUREN fields.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
	HOUREN	AMPM	HOUR[5:0]					
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	MINEN	MIN[6:0]						
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	SECEN	SEC[6:0]						
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit 23 – HOUREN Hour Alarm Enable

Value	Name	Description
0	DISABLED	The hour-matching alarm is disabled.
1	ENABLED	The hour-matching alarm is enabled.

Bit 22 – AMPM AM/PM Indicator
This field is the alarm field corresponding to the BCD-coded hour counter.

Bits 21:16 – HOUR[5:0] Hour Alarm
This field is the alarm field corresponding to the BCD-coded hour counter.

Bit 15 – MINEN Minute Alarm Enable

Value	Name	Description
0	DISABLED	The minute-matching alarm is disabled.
1	ENABLED	The minute-matching alarm is enabled.

Bits 14:8 – MIN[6:0] Minute Alarm
This field is the alarm field corresponding to the BCD-coded minute counter.

Bit 7 – SECEN Second Alarm Enable

Value	Name	Description
0	DISABLED	The second-matching alarm is disabled.
1	ENABLED	The second-matching alarm is enabled.

Bits 6:0 – SEC[6:0] Second Alarm
This field is the alarm field corresponding to the BCD-coded second counter.

26.6.7 RTC Time Alarm Register (UTC_MODE)

Name: RTC_TIMALR (UTC_MODE)
Offset: 0x10
Reset: 0x00000000
Property: Read/Write

This configuration is relevant only if UTC = 1 in RTC_MR.

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode register (SYSC_WPMR).

Bit	31	30	29	28	27	26	25	24
	UTC_TIME[31:24]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0
Bit	23	22	21	20	19	18	17	16
	UTC_TIME[23:16]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8
	UTC_TIME[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
	UTC_TIME[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 31:0 – UTC_TIME[31:0] UTC_TIME Alarm
This field is the alarm field corresponding to the UTC time counter. To change it, proceed as follows:
1. Disable the UTC alarm by clearing RTC_CALALR.UTCEN if it is not already cleared.
2. Change the UTC_TIME alarm value.
3. Enable the UTC alarm by setting RTC_CALALR.UTCEN.

26.6.8 RTC Calendar Alarm Register

Name: RTC_CALALR
Offset: 0x14
Reset: 0x01010000
Property: Read/Write

In UTC mode, this register view is not relevant, see 26.6.9. RTC_CALALR (UTC_MODE).

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode register (SYSC_WPMR).

To change one of the DATE, MONTH fields, it is recommended to disable the field before changing the value and then re-enable it after the change has been made. This requires up to three accesses to RTC_CALALR. The first access clears the enable corresponding to the field to change (DATEEN, MTHEN). If the field is already cleared, this access is not required. The second access performs the change of the value (DATE, MONTH). The third access is required to re-enable the field by writing 1 in DATEEN, MTHEN fields.

Bit	31	30	29	28	27	26	25	24
	DATEEN		DATE[5:0]					
Access	R/W		R/W	R/W	R/W	R/W	R/W	R/W
Reset	0		0	0	0	0	0	1

Bit	23	22	21	20	19	18	17	16
	MTHEN			MONTH[4:0]				
Access	R/W			R/W	R/W	R/W	R/W	R/W
Reset	0			0	0	0	0	1

Bit	15	14	13	12	11	10	9	8

Reset								

Bit	7	6	5	4	3	2	1	0
Access								
Reset								

Bit 31 – DATEEN Date Alarm Enable

Value	Name	Description
0	DISABLED	The date-matching alarm is disabled.
1	ENABLED	The date-matching alarm is enabled.

Bits 29:24 – DATE[5:0] Date Alarm
This field is the alarm field corresponding to the BCD-coded date counter.

Bit 23 – MTHEN Month Alarm Enable

Value	Name	Description
0	DISABLED	The month-matching alarm is disabled.
1	ENABLED	The month-matching alarm is enabled.

Bits 20:16 – MONTH[4:0] Month Alarm
This field is the alarm field corresponding to the BCD-coded month counter.

26.6.9 RTC Calendar Alarm Register (UTC_MODE)

Name: RTC_CALALR (UTC_MODE)
Offset: 0x14
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode register (SYSC_WPMR).

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access

Access								R/W
Reset								0

Bit 0 – UTCEN UTC Alarm Enable

Value	Name	Description
0	DISABLED	The UTC-matching alarm is disabled.
1	ENABLED	The UTC-matching alarm is enabled.

26.6.10 RTC Status Register

Name: RTC_SR
Offset: 0x18
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
			TDERR	CALEV	TIMEV	SEC	ALARM	ACKUPD
Access			R	R	R	R	R	R
Reset			0	0	0	0	0	0

Bit 5 – TDERR Time and/or Date Free Running Error
If the RTC is configured in UTC mode, the value returned by this field is not relevant.

Value	Name	Description
0	CORRECT	The internal free running counters are carrying valid values since the last read of the Status register (RTC_SR).
1	ERR_TIMEDATE	The internal free running counters have been corrupted (invalid date or time, non-BCD values) since the last read and/or they are still invalid.

Bit 4 – CALEV Calendar Event
The calendar event is selected in RTC_CR.TIMEVSEL and can be any one of the following events: week change, month change and year change. If the RTC is configured in UTC mode, the value returned by this field is not relevant.

Value	Name	Description
0	NO_CALEVENT	No calendar event has occurred since the last clear.
1	CALEVENT	At least one calendar event has occurred since the last clear.

Bit 3 – TIMEV Time Event
The time event is selected in RTC_CR.TIMEVSEL and can be any one of the following events: minute change, hour change, noon, midnight (day change). If the RTC is configured in UTC mode, the value returned by this field is not relevant.

Value	Name	Description
0	NO_TIMEVENT	No time event has occurred since the last clear.
1	TIMEVENT	At least one time event has occurred since the last clear.

Bit 2 – SEC Second Event

Value	Name	Description
0	NO_SECEVENT	No second event has occurred since the last clear.
1	SECEVENT	At least one second event has occurred since the last clear.

Bit 1 – ALARM Alarm Flag

Value	Name	Description
0	NO_ALARMEVENT	No alarm matching condition occurred.
1	ALARMEVENT	An alarm matching condition has occurred.

Bit 0 – ACKUPD Acknowledge for Update

Value	Name	Description
0	FREERUN	Time and calendar registers cannot be updated.
1	UPDATE	Time and calendar registers can be updated.

26.6.11 RTC Status Clear Command Register

Name: RTC_SCCR
Offset: 0x1C
Reset: –
Property: Write-only

To avoid missing clearing commands, wait for three slow clock cycles between two accesses to this register.

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Clears the corresponding status flag in the Status register (RTC_SR).

Bit	31	30	29	28	27	26	25	24

Reset			–	–	–	–	–	–

Bit 5 – TDERRCLR Time and/or Date Free Running Error Clear
If the RTC is configured in UTC mode, this bit has no effect.

Bit 4 – CALCLR Calendar Clear
If the RTC is configured in UTC mode, this bit has no effect.

Bit 3 – TIMCLR Time Clear
If the RTC is configured in UTC mode, this bit has no effect.

Bit 2 – SECCLR Second Clear

Bit 1 – ALRCLR Alarm Clear

Bit 0 – ACKCLR Acknowledge Clear

26.6.12 RTC Interrupt Enable Register

Name: RTC_IER
Offset: 0x20
Reset: –
Property: Write-only

This register can only be written if the WPITEN bit is cleared in the System Controller Write Protection Mode register (SYSC_WPMR).

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Enables the corresponding interrupt.

Bit	31	30	29	28	27	26	25	24

Access			W	W	W	W	W	W
Reset			–	–	–	–	–	–

Bit 5 – TDERREN Time and/or Date Error Interrupt Enable
If the RTC is configured in UTC mode, this bit has no effect.

Bit 4 – CALEN Calendar Event Interrupt Enable
If the RTC is configured in UTC mode, this bit has no effect.

Bit 3 – TIMEN Time Event Interrupt Enable
If the RTC is configured in UTC mode, this bit has no effect.

Bit 2 – SECEN Second Event Interrupt Enable

Bit 1 – ALREN Alarm Interrupt Enable

Bit 0 – ACKEN Acknowledge Update Interrupt Enable

26.6.13 RTC Interrupt Disable Register

Name: RTC_IDR
Offset: 0x24
Reset: –
Property: Write-only

This register can only be written if the WPITEN bit is cleared in the System Controller Write Protection Mode register (SYSC_WPMR).

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Disables the corresponding interrupt.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								
Bit	23	22	21	20	19	18	17	16

Bit 5 – TDERRDIS Time and/or Date Error Interrupt Disable
If the RTC is configured in UTC mode, this bit has no effect.

Bit 4 – CALDIS Calendar Event Interrupt Disable
If the RTC is configured in UTC mode, this bit has no effect.

Bit 3 – TIMDIS Time Event Interrupt Disable
If the RTC is configured in UTC mode, this bit has no effect.

Bit 2 – SECDIS Second Event Interrupt Disable

Bit 1 – ALRDIS Alarm Interrupt Disable

Bit 0 – ACKDIS Acknowledge Update Interrupt Disable

26.6.14 RTC Interrupt Mask Register

Name: RTC_IMR
Offset: 0x28
Reset: 0x00000000
Property: Read-only

The following configuration values are valid for all listed bit names of this register:

0: The corresponding interrupt is disabled.

1: The corresponding interrupt is enabled.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16

Bit 3 – NVCALALR Non-valid Calendar Alarm

Value	Description
0	No invalid data has been detected in RTC_CALALR (Calendar Alarm register).
1	RTC_CALALR has contained invalid data since it was last programmed.

Bit 2 – NVTIMALR Non-valid Time Alarm

Value	Description
0	No invalid data has been detected in RTC_TIMALR (Time Alarm register).
1	RTC_TIMALR has contained invalid data since it was last programmed.

Bit 1 – NVCAL Non-valid Calendar

Value	Description
0	No invalid data has been detected in RTC_CALR (Calendar register).
1	RTC_CALR has contained invalid data since it was last programmed.

Bit 0 – NVTIM Non-valid Time

Value	Description
0	No invalid data has been detected in RTC_TIMR (Time register).
1	RTC_TIMR has contained invalid data since it was last programmed.

26.6.16 RTC TimeStamp Time Register 0

Name: RTC_TSTR0
Offset: 0xB0
Reset: 0x00000000
Property: Read-only

These fields are valid for non-UTC mode only.

RTC_TSTR0 reports the timestamp of the first tamper event after reading RTC_TSSR0.

Bit	31	30	29	28	27	26	25	24
	BACKUP				TEVCNT[3:0]

Bit 31 – BACKUP System Mode of the Tamper (cleared by reading RTC_TSSR0)

Value	Description
0	The state of the system is different from Backup mode when the tamper event occurs.
1	The system is in Backup mode when the tamper event occurs.

Bits 27:24 – TEVCNT[3:0] Tamper Events Counter (cleared by reading RTC_TSSR0)
Each time a tamper event occurs, this counter is incremented. This counter saturates at 15. Once this value is reached, it is no more possible to know the exact number of tamper events.
If this field is not null, this implies that at least one tamper event occurs since last register reset and that the values stored in timestamping registers are valid.

Bit 22 – AMPM AM/PM Indicator of the Tamper (cleared by reading RTC_TSSR0)

Bits 21:16 – HOUR[5:0] Hours of the Tamper (cleared by reading RTC_TSSR0)

Bits 14:8 – MIN[6:0] Minutes of the Tamper (cleared by reading RTC_TSSR0)

Bit 31 – BACKUP System Mode of the Tamper (cleared by reading RTC_TSSR1)

Value	Description
0	The state of the system is different from Backup mode when the tamper event occurs.
1	The system is in Backup mode when the tamper event occurs.

26.6.20 RTC TimeStamp Date Register

Name: RTC_TSDRx
Offset: 0xB4 + x*0x0C [x=0..1]
Reset: 0x00000000
Property: Read-only

These fields contain the date and the source of a tamper occurrence if RTC_TSTR0.TEVCNT field is not null.

These fields are relevant for non-UTC mode only.

RTC_TSDR0 reports the timestamp of the first tamper event after reading RTC_TSSR0, and RTC_TSDR1 reports the timestamp of the last tamper event.

Bit	31	30	29	28	27	26	25	24

Bit 0 – DWDTSW Dual WatchDog Timer Event (cleared on read)

27. Shutdown Controller (SHDWC)

27.1 Description

The Shutdown Controller (SHDWC) controls the VDDIO and VDDCORE power supplies and the wake-up detection on debounced input lines.

27.2 Embedded Characteristics

- Shutdown Logic
  - Software assertion of the Shutdown Output Pin (SHDN)
  - Programmable de-assertion from wake-up events
- Wake-Up Logic
  - Programmable wake-up event detection through WKUP input pins and internal events (RTC, RTT and Security Module)
- Low-Power Logic
  - Automatic/manual control of the LPM output pin

27.3 Block Diagram

Figure 27-1. SHDWC Block Diagram

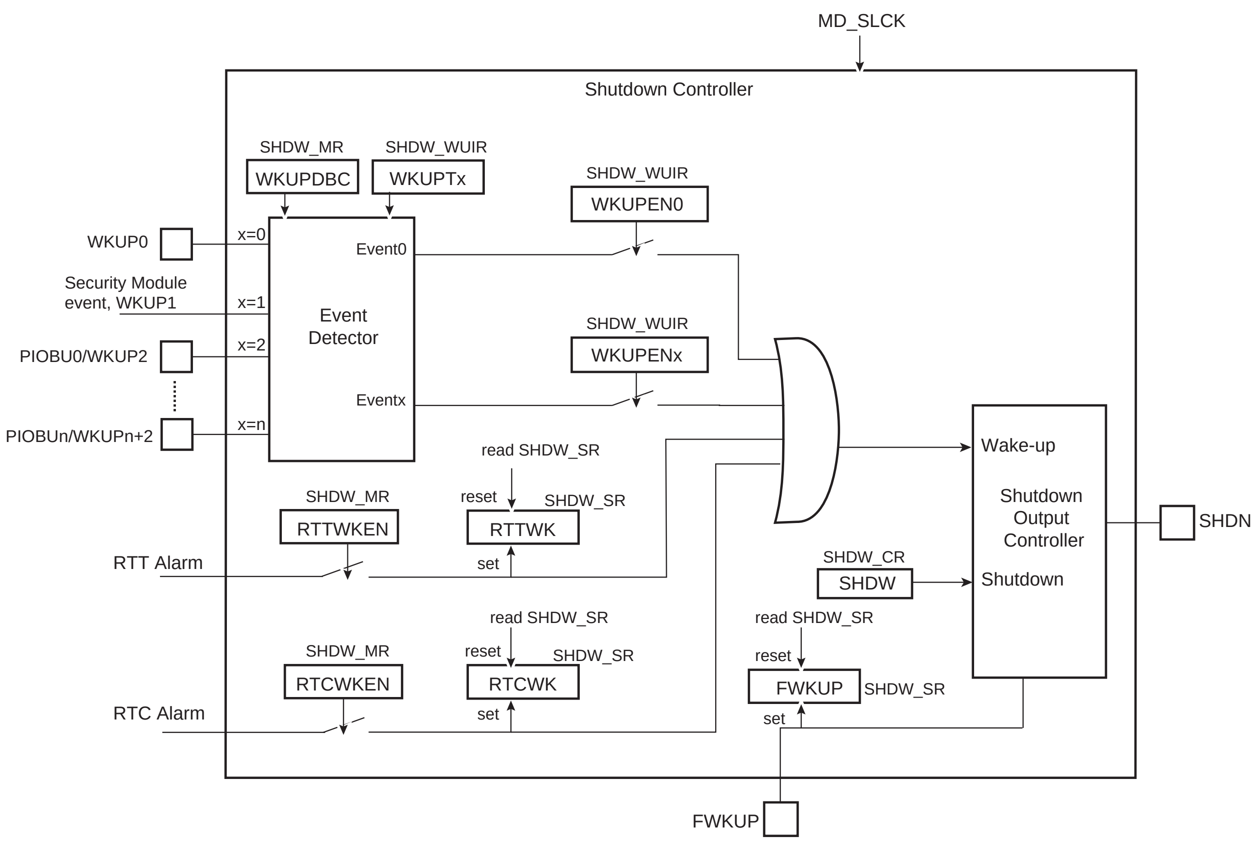

Figure 27-2. LPM Pad Management

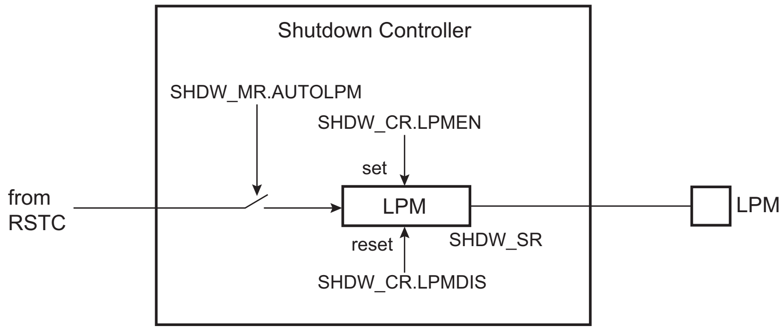


27.4 I/O Lines Description

Table 27-1. I/O Lines Description

Name	Description	Type
WKUP0	Wake-up inputs	Input
PIOBU0-3	Wake-up inputs, WKUP(2-5)	Input
SHDN	Shutdown output	Output
LPM	Low-Power mode	Output

27.5 Product Dependencies

27.5.1 Power Management

The SHDWC is continuously clocked by the Monitoring Domain Slow Clock (MD_SLCK). The Power Management Controller has no effect on the behavior of the SHDWC.

27.6 Functional Description

The SHDWC manages the main power supply. To do so, it is supplied with VDDBU and manages wake-up input pins and one output pin, SHDN.

A typical application connects the pin SHDN to the enable input of the device's power supply circuit. The wake-up inputs (WKUPn) connect to any push-buttons or signal that wake up the system.

The software is able to control the pin SHDN by writing the Shutdown Control Register (SHDW_CR) with the bit SHDW at 1. The shutdown is taken into account only two MD_SLCK cycles after the write of SHDW_CR. This register is password-protected and so the value written should contain the correct key for the command to be taken into account. As a result, the SHDN pin is driven low and the system should be powered down.

The SHDWC manages the LPM pin which is used to indicate to an external power supply that the drive of the system can be reduced. This pin can be configured to be automatically managed by software or by hardware.

27.6.1 Wake-up Inputs

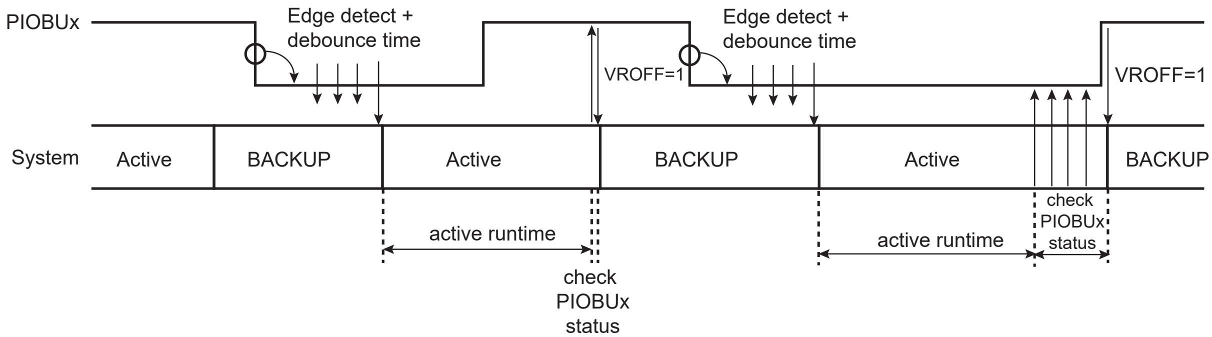
Any level change on a PIOBUx, WKUP pin, or Security Module event, can trigger a wake-up. Wake-up is configured in the Mode register (SHDW_MR) and Wakeup Inputs register (SHDW_WUIR). The transition detector can be programmed to detect either a positive or negative transition on any PIOBUx, WKUP pin. The detection can also be disabled. Programming is performed by enabling the Wake-up Input (WKUPENx bit) and defining the Wake-up Input Type (WKUPTx bit) in the SHDW_WUIR.

Moreover, a debouncing circuit can be programmed for PIOBUx, WKUP. The debouncing circuit filters pulses on PIOBUx, WKUP shorter than the programmed value in SHDW_MR.WKUPDBC. If the programmed level change is detected on a pin, a counter starts. When the counter reaches the value programmed in WKUPDBC, the SHDN pin is released. If a new input change is detected before the counter reaches the corresponding value, the counter is stopped and cleared. One counter is shared among all PIOBUx, WKUP inputs and all programmed level detection is merged into this counter. The WKUPISx bit of the Status register (SHDW_SR) reports the detection of the programmed events on PIOBUx, WKUP with a reset after the read of SHDW_SR.

Figure 27-3. Entering and Exiting Backup Mode with a PIOBUx, WKUP Pin

WKUPDBC > 0

WKUPTx=0



The SHDWC can be programmed so as to activate the wake-up using the RTC and RTT alarms or the Security Module event (detection of the rising edge event is synchronized with MD_SLCK). This is done by writing SHDW_MR.RTCWKEN or RTTWKEN, or by writing the SHDW_WUIR.WKUPEN1 (Security Module event is connected on the WKUP1 wake-up input). When enabled, the detection of the RTC or RTT alarms or the Security Module event is reported in SHDW_SR.RTCWK, RTTWK or WKUPIS1. These bits are cleared after reading SHDW_SR. When using the RTC or RTT alarms or the Security Module event to wake up the system, the user must ensure that the RTC and RTT alarm status flags and the Security Module event flag are cleared before shutting down the system. Otherwise, no rising edge of the status flags may be detected and the wake-up fails

27.6.2 Low-Power Mode Pin Control

The SHDWC manages the LPM pin which is used to indicate to an external power supply to enter or exit a special powering state. The LPM pin can be configured by software or by hardware.

To configure LPM with software:

- Set SHDWC_CR.LPMEN to set LPM 'high' (VBAT level)
- Set SHDWC_CR.LPMDIS to set LPM 'low' (VBAT level)

Writing both SHDW_CR.LPMEN and SHDW_CR.LPMDIS has no effect.

For LPM configuration via hardware, SHDW_MR.AUTOLPM must be set to '1'. The configuration is done automatically by the SHDWC and the RSTC when entering and exiting ULP mode 2:

- The LPM pin is set 'high' when the system enters ULP mode 2
- The LPM pin is set 'low' when the system exits ULP mode 2

By default, at the first power-up, LPM starts at low-level.

27.7 Register Summary

Offset	Name	Bit Pos.	7	6	5	4	3	2	1	0
0x00	SHDW_CR	31:24	KEY[7:0]

Bits 31:24 – KEY[7:0] Password

Value	Name	Description
0xA5	PASSWD	Writing any other value in this field aborts the write operation.

Bit 22 – LPMDIS LPM Pad Disable

Value	Description
0	No effect.
1	The LPM pad is set low (external regulator is set in standard powering state).

Bit 21 – LPMEN LPM Pad Enable

Value	Description
0	No effect.
1	The LPM pad is set high (external regulator is set in special powering state).

Bit 0 – SHDW Shutdown Command

Value	Description
0	No effect.
1	If KEY value is correct, asserts the SHDN pin.

27.7.2 SHDWC Mode Register

Name: SHDW_MR
Offset: 0x04
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode Register (SYSC_WPMR).

Bit	31	30	29	28	27	26	25	24
						WKUPDBC[2:0]

Bits 26:24 – WKUPDBC[2:0] Wake-up Inputs Debouncer Period

Value	Name	Description
0	IMMEDIATE	Immediate, no debouncing, detected active at least on one MD_SLCK edge
1	3_SLCK	PIOBUx shall be in its active state for at least 3 MD_SLCK periods
2	32_SLCK	PIOBUx shall be in its active state for at least 32 MD_SLCK periods
3	512_SLCK	PIOBUx shall be in its active state for at least 512 MD_SLCK periods
4	4096_SLCK	PIOBUx shall be in its active state for at least 4,096 SLCK periods
5	32768_SLCK	PIOBUx shall be in its active state for at least 32,768 MD_SLCK periods

Bit 20 – AUTOLPM Automatic LPM Pad Management

Value	Description
0	The LPM pad is never automatically modified by the RSTC.
1	The LPM pad is automatically modified by the RSTC when the system goes into or out of the ULP mode 2.

Bit 17 – RTCWKEN Real-time Clock Wake-up Enable

Value	Description
0	The RTC Alarm signal has no effect on the SHDWC.
1	The RTC Alarm signal forces the de-assertion of the SHDN pin.

Bit 16 – RTTWKEN Real-time Timer Wake-up Enable

Value	Description
0	The RTT Alarm signal has no effect on the SHDWC.
1	The RTT Alarm signal forces the de-assertion of the SHDN pin.

27.7.3 SHDWC Status Register

Name: SHDW_SR
Offset: 0x08
Reset: 0x00000000
Property: Read-only

Note: The events are detected only when the system is in Backup mode.

Bit	7	6	5	4	3	2	1	0
			RTCWK	RTTWK				WKUPS
Access			R	R				R
Reset			0	0				0

Bits 16, 17, 18, 19, 20, 21 – WKUPISx Wake-up x Input Status

Value	Name	Description
0	DISABLE	The corresponding wake-up input is disabled, or was inactive at the time the debouncer triggered a wake-up event.
1	ENABLE	The corresponding wake-up input was active at the time the debouncer triggered a wake-up event.

Bit 8 – LPM Low-Power Mode Pad Status

Value	Description
0	The LPM pad is currently set to 0.
1	The LPM pad is currently set to 1.

Bit 5 – RTCWK Real-time Clock Wake-up

Value	Description
0	No wake-up alarm from the RTC occurred since the last read of SHDW_SR.
1	At least one wake-up alarm from the RTC occurred since the last read of SHDW_SR.

Bit 4 – RTTWK Real-time Timer Wake-up

Value	Description
0	No wake-up alarm from the RTT occurred since the last read of SHDW_SR.
1	At least one wake-up alarm from the RTT occurred since the last read of SHDW_SR.

Bit 0 – WKUPS PIOBU, WKUP Wake-up Status

Value	Name	Description
0	NO	No wake-up due to the assertion of the PIOBU, WKUP pins has occurred since the last read of SHDW_SR.
1	PRESENT	At least one wake-up due to the assertion of the PIOBU, WKUP pins has occurred since the last read of SHDW_SR.

27.7.4 SHDWC Wake-up Inputs Register

Name: SHDW_WUIR
Offset: 0x0C
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode Register (SYSC_WPMR).

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
			WKUPT5	WKUPT4	WKUPT3	WKUPT2	WKUPT1	WKUPT0

Reset			0	0	0	0	0	0

Bits 16, 17, 18, 19, 20, 21 – WKUPTx Wake-up Input x Type
As the Security Module event is connected to the WKUP1 wake-up input, WKUPT1 must be set to 1.

Value	Description
0	A falling edge followed by a low level on the corresponding wake-up input, for a period defined by WKUPDBC, forces wake-up of the core power supply.
1	A rising edge followed by a high level on the corresponding wake-up input, for a period defined by WKUPDBC, forces wake-up of the core power supply.

Bits 0, 1, 2, 3, 4, 5 – WKUPENx Wake-up Input x Enable

Value	Description
0	The corresponding wake-up input has no wake-up effect.
1	The corresponding wake-up input forces wake-up of the core power supply.

28. 64-bit Periodic Interval Timer (PIT64B)

28.1 Description

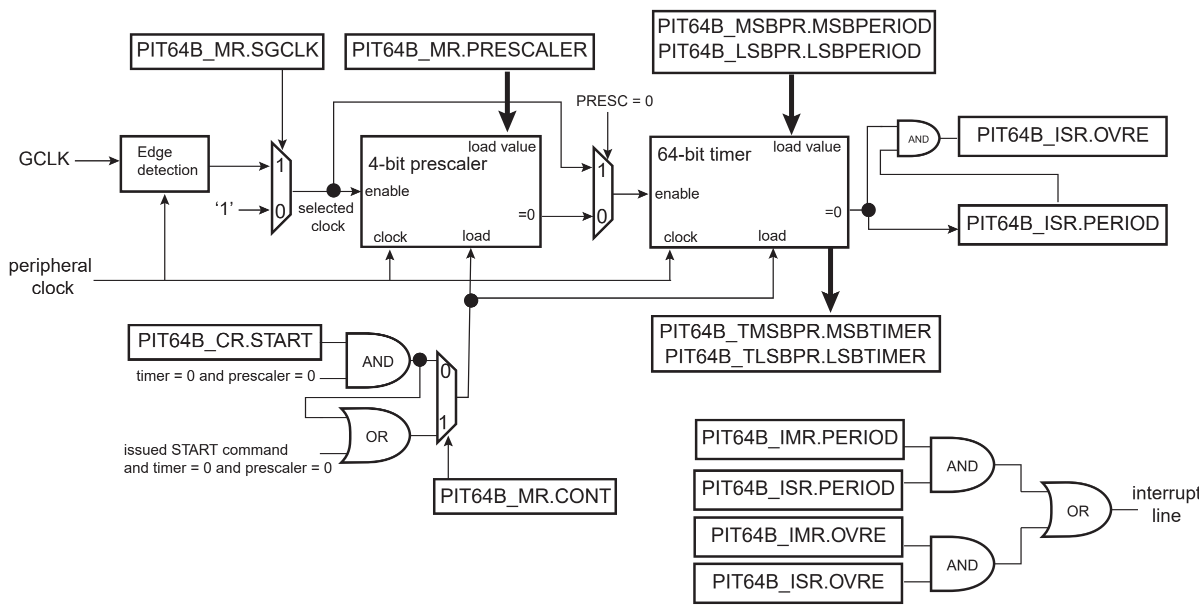
The 64-bit Periodic Interval Timer (PIT64B) provides the operating system scheduler interrupt, as well as any periodic source of interrupt to software. It is designed to offer maximum accuracy and efficient management, even for systems with long response times.

28.2 Embedded Characteristics

- 4-bit Prescaler
- 64-bit Timer
- Single Shot or Continuous Mode
- Safety/Security Access Reports
- Register Write protection

28.3 Block Diagram

Figure 28-1. Block Diagram



28.4 Product Dependencies

28.4.1 Power Management

The Power Management Controller (PMC) controls the PIT64B clock in order to save power. The programmer must first enable the PIT64B clock in the PMC before using the PIT64B.

After a hardware reset, the PIT64B clock is disabled by default.

28.4.2 Interrupt Generation

The PIT64B interface has an interrupt line connected to the Interrupt Controller.

Handling the PIT64B interrupt requires programming the Interrupt Controller before configuring the PIT64B.

28.5 Functional Description

28.5.1 Timer Clock Source

The two clock sources for the 64-bit timer are the peripheral clock and the generic clock (GCLK), which can be fully asynchronous to the peripheral clock. The selected clock can be prescaled before triggering the 64-bit timer.

The GCLK is selected as source clock for the prescaler when the SGCLK bit, in the Mode register (PIT64B_MR), is written to 1. The prescaler is active as soon as PIT64B_MR.PRESCALER>0.

If PIT64B_MR.PRESCALER=0, the timer is triggered either on each rising edge detection event of the GCLK if PIT64B_MR.SGCLK is written to 1, or on each rising edge of the peripheral clock.

If GCLK is selected, the frequency must be at least 3 times lower than the peripheral clock.

28.5.2 Single Period Mode

When the PIT64B_MR.CONT bit is written to 0, the PIT64B produces a single timer event. The timer period starts as soon as the START bit, in the Control register (PIT64B_CR), is written to 1. The period is defined by configuring the LSBPERIOD field in the LSB Period register (PIT64B_LSBPR) and the MSBPERIOD field in the MSB Period register (PIT64B_MSBPR). When the START command is issued, the 64-bit timer loads 0 and increments up to LSBPERIOD and MSBPERIOD field value minus 1, then automatically reloads 0 and stops.

When time reaches the maximum value, the PERIOD flag, in the Interrupt Status register (PIT64B_ISR), is set. No other period will be started until a new START command is issued.

After a period is started and while it is not elapsed, any new values written in PIT64B_MR, PIT64B_LSBPR or PIT64B_MSBPR have no effect on the current period if bit PIT64B_MR.SMOD=0 (see Figure Single Waveform in Single Period Mode if bit PIT64B_MR.SMOD=0

If PIT64B_MR.SMOD=1 a start is also performed as soon as PIT64B_LSBPR is written, thus a modification of the period can be performed on-the-fly with a single write operation if the period requires no more than 32 bits. When writing a 64-bit value, the 32-bit MSB part must be configured first, followed by the 32-bit LSB part (see Figure Waveform in Single Period Mode if bit PIT64B_MR.SMOD=1). When configuring a value lower or equal to 32 bits after processing a period defined on 64 bits, first PIT64B_MSBPR must be written to 0, and then the 32-bit LSB must be written into PIT64B_LSBPR.

If PIT64B_CR.SWRST is written to 1, the current period is immediately stopped.

Figure 28-2. Single Waveform in Single Period Mode if bit PIT64B_MR.SMOD=0

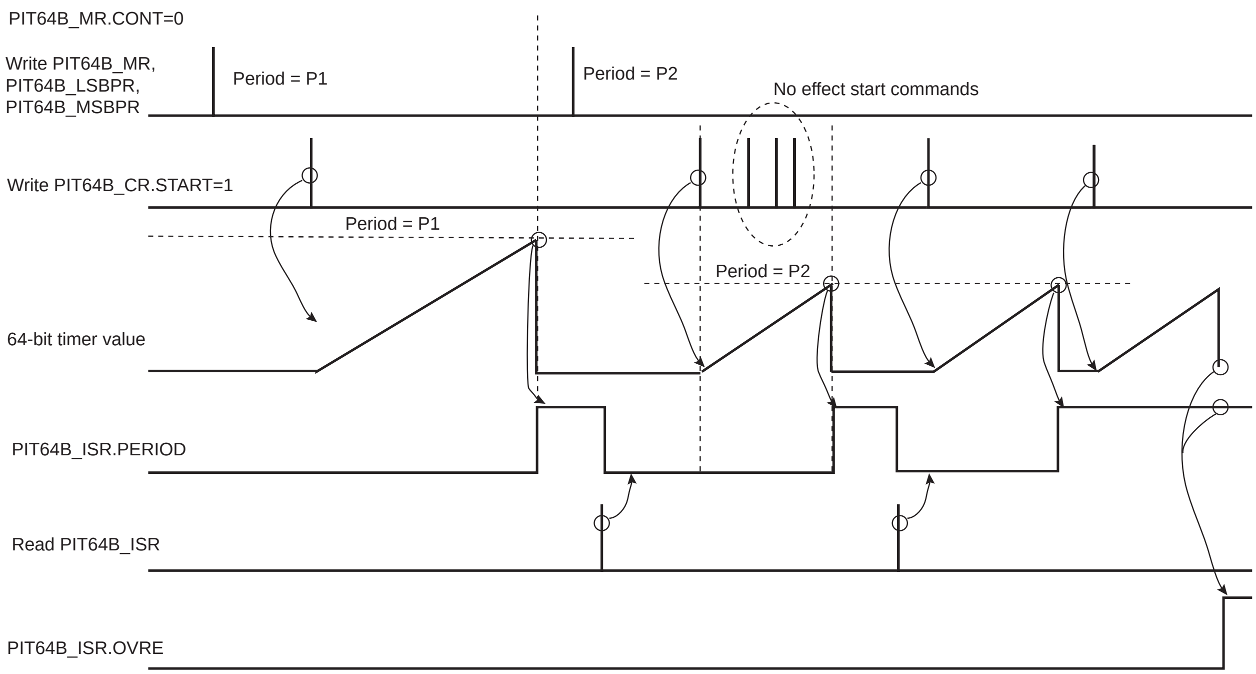


Figure 28-3. Waveform in Single Period Mode if bit PIT64B_MR.SMOD=1

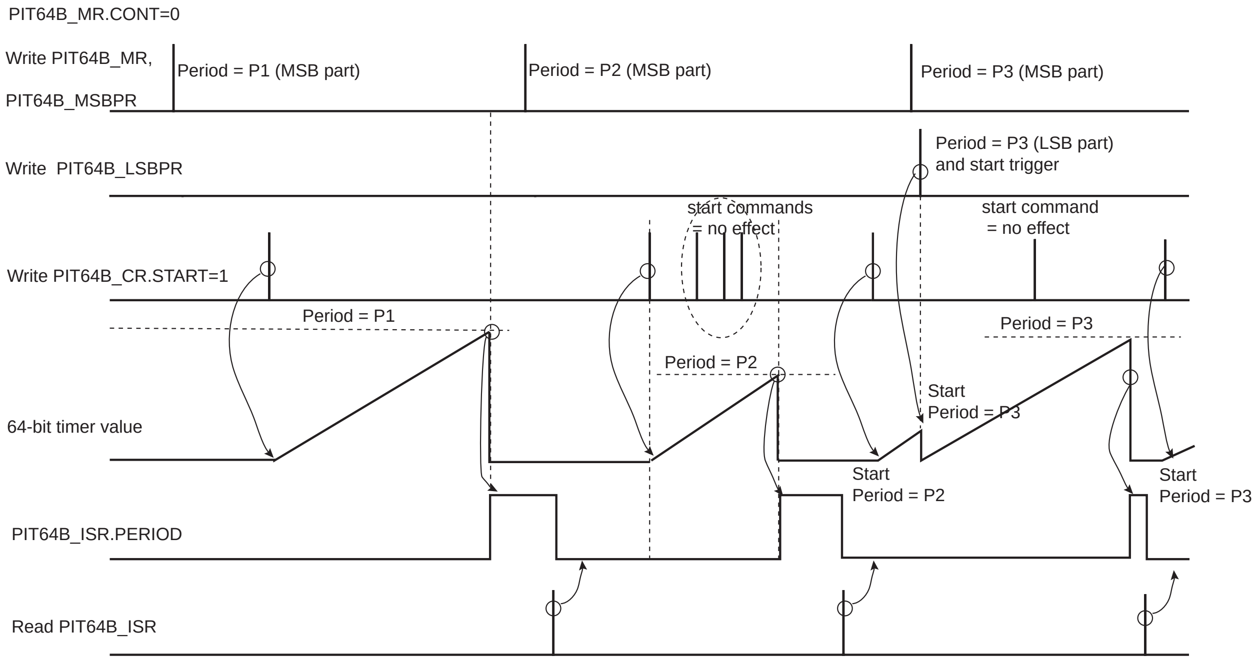

28.5.3 Continuous Period Mode

When the PIT64B_MR.CONT bit is written to 1, the PIT64B continuously produces timer events. The timer is started as soon as the PIT64B_CR.START bit is written to 1. The period is defined by configuring the PIT64B_LSBPR.LSBPERIOD field and PIT64B_MSBPR.MSBPERIOD field. When the START command is issued, the 64-bit timer loads 0 and increments up to LSBPERIOD and MSBPERIOD field value minus 1, then automatically reloads 0 anc restarts a new counting period until bit PIT64B_CR.SWRST is written to 1.

When the timer reaches its maximum value, the flag PIT64B_ISR.PERIOD is set. PIT64B_ISR.PERIOD is cleared when reading PIT64B_ISR. If a new period elapses and the PIT64B_ISR.PERIOD is 1, the PIT64B_ISR.OVRE flag is set to indicate a potential latency at system level

After the START command has been issued, any new values written in PIT64B_MR, PIT64B_LSBPR or PIT64B_MSBPR have no effect on the current period if bit PIT64B_MR.SMOD=0 (see Figure Waveform in Continuous Period Mode if the bit PIT64B_MR.SMOD=0). A software reset must be issued before configuring new values in PIT64B_LSBPR and PIT64B_MSBPR if bit PIT64B_MR.SMOD=0.

If PIT64B_MR.SMOD=1 a start can be also performed as soon as PIT64B_LSBPR is written, thus a modification of the period can be performed on-the-fly with a single write operation if the period requires no more than 32 bits. When writing a 64-bit value, the 32-bit MSB part must be configured first followed by a 32-bit LSB part (see Figure Waveform in Continuous Period Mode if the bit PIT64B_MR.SMOD=1). When configuring a value lower or equal to 32 bits after processing a period defined on 64 bits, first PIT64B_MSBPR must be written to 0, and then the 32-bit LSB must be written into PIT64B_LSBPR.

If PIT64B_CR.SWRST is written to 1, the current period is immediately stopped.

Figure 28-4. Waveform in Continuous Period Mode if bit PIT64B_MR.SMOD=0

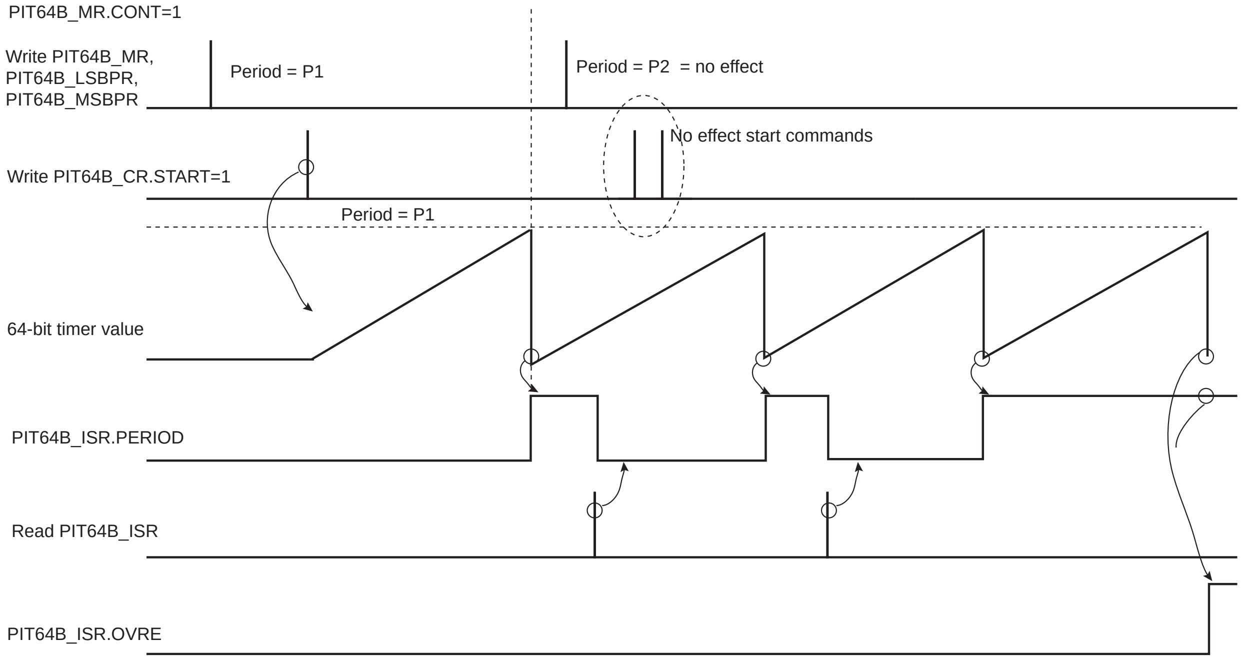

Figure 28-5. Waveform in Continuous Period Mode if bit PIT64B_MR.SMOD=1

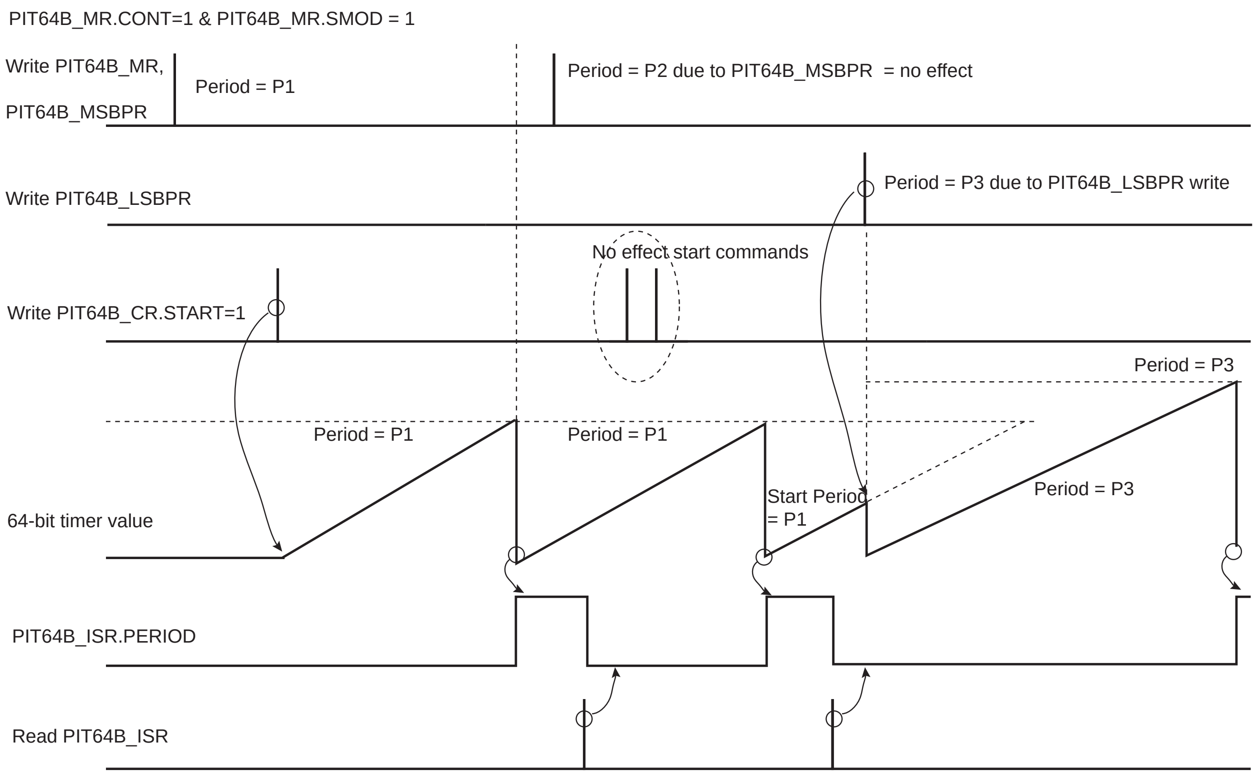

28.5.4 Security and Safety Analysis and Reports

Several types of checks are performed when the PIT64B is running.

The peripheral clock of the PIT64B is monitored by a specific circuitry to detect abnormal waveforms on the internal clock that may affect the behavior of the PIT64B. Corruption on the triggering edge of the clock or a pulse with a minimum duration may be identified. If the CGD flag is set in the Write Protection Status register (PIT64B_WPSR), an abnormal condition occurred on the peripheral clock. This flag is not set under normal operating conditions.

The internal timer sequence of the PIT64B is also monitored and if an abnormal state is detected, the flag PIT64B_WPSR.SEQE is set. This flag is not set under normal operating conditions.

The software accesses to the PIT64B are monitored and if an incorrect access is performed, the flag PIT64B_WPSR.SWE is set. The type of incorrect/abnormal software access is reported in the PIT64B_WPSR.SWETYP field (see PIT64B Write Protection Status Register for details), e.g., writing PIT64B_MR, PIT64B_LSBPR (if PIT64B_MR.SMOD=0), PIT64B_MSBPR (if PIT64B_MR.SMOD=0) when the timer is running (after a START command has been issued) is an error. PIT64B_WPSR.ECLASS is an indicator reporting the criticality of the SWETYP report.

The flags CGD, SEQE, SWE and WPVS are automatically cleared when PIT64B_WPSR is read.

If one of these flags is set, the PIT64B_ISR.SECE flag is set and can trigger an interrupt if the SECE bit, in the Interrupt Mask register (PIT64B_IMR), is '1'. SECE is cleared by reading PIT64B_ISR.

28.5.5 Register Write Protection

To prevent any single software error from corrupting PIT64B behavior, certain registers in the address space can be write-protected by setting the WPEN (Write Protection Enable), WPITEN (Write Protection Interrupt Enable), and/or WPCREN (Write Protection Control Enable) bits in the PIT64B Write Protection Mode Register (PIT64B_WPMR).

If a write access to a write-protected register is detected, the WPVS (Write Protection Violation Status) flag in the PIT64B Write Protection Status Register (PIT64B_WPSR) is set and the WPVSRC (Write Protection Violation Source) field indicates the register in which the write access has been attempted.

The WPVS bit is automatically cleared after reading PIT64B_WPSR.

The following registers can be write-protected when WPEN is set in PIT64B_WPMR:

- PIT64B Mode Register
- PIT64B LSB Period Register
- PIT64B MSB Period Register

Note: PIT64B LSB Period Register and PIT64B MSB Period Register are not write-protected if PIT64B_MR.SMOD=1.

The following registers can be write-protected when WPITEN is set in PIT64B_WPMR:

- PIT64B Interrupt Enable Register
- PIT64B Interrupt Disable Register

The following register can be write-protected when WPCREN is set in PIT64B_WPMR:

- PIT64B Control Register

28.6 Register Summary

Offset	Name	Bit Pos.	7	6	5	4	3	2	1	0

28.6.1 PIT64B Control Register

Name: PIT64B_CR
Offset: 0x00
Reset: –
Property: Write-only

This register can only be written if the WPCREN bit is cleared in the PIT64B Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
								SWRST
Access								W
Reset								–

Bit	7	6	5	4	3	2	1	0
								START
Access								W
Reset								–

Bit 8 – SWRST Software Reset

Value	Description
0	No effect.
1	Performs a software reset, clears the configuration and stops any timer period in progress.

Bit 0 – START Start Timer

Value	Description
0	No effect.
1	The timer counter is started for 1 or more periods. If the START command is applied during a non-elapsed timer period, there is no effect. Thus, in Continuous mode, the SWRST command is the only command to stop the PIT64B. If PIT64B_MR.SMOD=1 a start is also performed as soon as PIT64B_LSBPR is written (see 28.5.2. Single Period Mode and 28.5.3. Continuous Period Mode).

28.6.2 PIT64B Mode Register

Name: PIT64B_MR
Offset: 0x04
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the PIT64B Write Protection Mode Register.

When the timer is running, writing a value to this register has no effect. The value written is this register is loaded anytime before a START command is issued.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
					PRESCALER[3:0]			
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bit	7	6	5	4	3	2	1	0
				SMOD	SGCLK			CONT
Access				R/W	R/W			R/W
Reset				0	0			0

Bits 11:8 – PRESCALER[3:0] Prescaler Period

Value	Description
0	A prescaler divider of 1 is used.
1-15	The 64-bit timer is incremented at each (PRESCALER+1)x selected period (see SGCLK).

Bit 4 – SMOD Start Mode

Value	Description
0	Writing PIT64B_LSBPR does not start the timer period.
1	Writing PIT64B_LSBPR starts the timer period.

Bit 3 – SGCLK Generic Clock Selection Enable
If GCLK is asynchronous to the peripheral clock, a jitter of 1 peripheral clock period is created on the periodic interval event when Continuous mode is selected.

Value	Description
0	The prescaler is triggered at each rising edge of “Peripheral clock” and the timer is triggered.
1	GCLK clock is selected as clock source of the 8-bit prescaler.

Bit 0 – CONT Continuous Mode

Value	Description
0	A single period interrupt is generated from a START command.
1	Continuous periodic interrupts are generated after a single START command.

28.6.3 PIT64B LSB Period Register

Name: PIT64B_LSBPR
Offset: 0x08
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the PIT64B Write Protection Mode Register or if PIT64B_MR.SMOD=1.

When the timer is running, if PIT64B_MR.SMOD=0, writing a value to this register has no effect. The value written is this register must be loaded anytime before a START command is issued if PIT64B_MR.SMOD=0. If PIT64B_MR.SMOD=1, a write access to this register restarts a timer period.

Bit	31	30	29	28	27	26	25	24
	LSBPERIOD[31:24]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 31:0 – LSBPERIOD[31:0] 32 LSB of the Timer Period
This field defines the 32 LSB of the timer period. The timer period is defined by selected clock x {MSBPERIOD,LSBPERIOD}.

28.6.4 PIT64B MSB Period Register

Name: PIT64B_MSBPR
Offset: 0x0C
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the PIT64B Write Protection Mode Register.

When the timer is running, if PIT64B_MR.SMOD=0, writing a value to this register has no effect. The value written is this register must be loaded anytime before a START command is issued if PIT64B_MR.SMOD=0.

Bit	31	30	29	28	27	26	25	24
	MSBPERIOD[31:24]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

	MSBPERIOD[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 31:0 – MSBPERIOD[31:0] 32 MSB of the Timer Period
This field defines the 32 MSB of the timer period. The timer period is defined by selected clock x {MSBPERIOD,LSBPERIOD}.

28.6.5 PIT64B Interrupt Enable Register

Name: PIT64B_IER
Offset: 0x10
Reset: –
Property: Write-only

This register can only be written if the WPITEN bit is cleared in the PIT64B Write Protection Mode Register.

The following configuration values are valid for all listed bit names of this register:

0: No effect

1: Enables the corresponding interrupt

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16

Bit 4 – SECE Safety and/or Security Report Interrupt Enable

Bit 1 – OVRE Overrun Error Interrupt Enable

Bit 0 – PERIOD Elapsed Timer Period Interrupt Enable

28.6.6 PIT64B Interrupt Disable Register

Name: PIT64B_IDR
Offset: 0x14
Reset: –
Property: Write-only

This register can only be written if the WPITEN bit is cleared in the PIT64B Write Protection Mode Register.

The following configuration values are valid for all listed bit names of this register:

0: No effect

1: Disables the corresponding interrupt

Bit	31	30	29	28	27	26	25	24
Access

Bit 4 – SECE Safety and/or Security Report Interrupt Disable

Bit 1 – OVRE Overrun Error Interrupt Disable

Bit 0 – PERIOD Elapsed Timer Period Interrupt Disable

28.6.7 PIT64B Interrupt Mask Register

Name: PIT64B_IMR
Offset: 0x18
Reset: 0x00000000
Property: Read-only

The following configuration values are valid for all listed bit names of this register:

0: Corresponding interrupt is not enabled.

1: Corresponding interrupt is enabled.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16

Access								
Reset								

Bit	7	6	5	4	3	2	1	0
				SECE			OVRE	PERIOD
Access				R			R	R
Reset				0			0	0

Bit 4 – SECE Safety/Security Report (cleared on read)

Value	Description
0	There has been no security report in PIT64B_WPSR since the last read of PIT64B_ISR.
1	One security flag has been set in PIT64B_WPSR since the last read of PIT64B_ISR.

Bit 1 – OVRE Overrun Error (cleared on read)

Value	Description
0	No multiple rollovers occurred since the last read of PIT64B_ISR.
1	More than 1 rollover occurred since the last read of PIT64B_ISR.

Bit 0 – PERIOD Elapsed Timer Period Status Flag (cleared on read)

Value	Description
0	No timer rollover occurred since the last read of PIT64B_ISR.
1	A timer rollover occurred since the last read of PIT64B_ISR.

28.6.9 PIT64B Timer LSB Register

Name: PIT64B_TLSBR
Offset: 0x20
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
	LSBTIMER[31:24]							
Access	R	R	R	R	R	R	R	R

Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bits 31:0 – LSBTIMER[31:0] Current 32 LSB of the Timer
This field returns the 32 LSB of the current timer value.

28.6.10 PIT64B Timer MSB Register

Name: PIT64B_TMSBR
Offset: 0x24
Reset: 0x00000000
Property: Read-only

When operating with a timer value greater than 32 bits (PIT64B_MSBPR.MSBPERIOD > 0), the PIT64B_TLSBR must be read first, followed by the read of PIT64B_TMSBR. This sequence generates an atomic read of the 64-bit timer value whatever the lapse of time between the accesses. When operating with a timer value up to 32 bits (PIT64B_MSBPR.MSBPERIOD=0), reading PIT64B_TMSBR is not required.

Bit	31	30	29	28	27	26	25	24

	WPKEY[15:8]							
Access	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8
	WPKEY[7:0]							
Access	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
				FIRSTE		WPCREN	WPITEN	WPEN
Access				R/W		R/W	R/W	R/W
Reset				0		0	0	0

Bits 31:8 – WPKEY[23:0] Write Protection Key

Value	Name	Description
0x504954	PASSWD	Writing any other value in this field aborts the write operation of the WPCREN, WPITEN and WPEN bits. Always reads as 0.

Bit 4 – FIRSTE First Error Report Enable

Value	Description
0	The last write protection violation source is reported in PIT64B_WPSR.WPVSRC and the last software control error type is reported in PIT64B_WPSR.SWETYP. The PIT64B_ISR.SECE flag is set at the first error occurring within a series.
1	Only the first write protection violation source is reported in PIT64B_WPSR.WPVSRC and only the first software control error type is reported in PIT64B_WPSR.SWETYP. The PIT64B_ISR.SECE flag is set at the first error occurring within a series.

Bit 2 – WPCREN Write Protection Control Enable

Value	Description
0	Disables the write protection on control register if WPKEY corresponds to 0x504954 (“PIT” in ASCII).
1	Enables the write protection on control register if WPKEY corresponds to 0x504954 (“PIT” in ASCII).

Bit 1 – WPITEN Write Protection Interruption Enable

Value	Description
0	Disables the write protection on interrupt registers if WPKEY corresponds to 0x504954 (“PIT” in ASCII).
1	Enables the write protection on interrupt registers if WPKEY corresponds to 0x504954 (“PIT” in ASCII).

Bit 0 – WPEN Write Protection Enable
See Section 6.5 “Register Write Protection” for the list of registers that can be protected.

Value	Description
0	Disables the write protection if WPKEY corresponds to 0x504954 (“PIT” in ASCII).
1	Enables the write protection if WPKEY corresponds to 0x504954 (“PIT” in ASCII).

28.6.12 PIT64B Write Protection Status Register

Name: PIT64B_WPSR
Offset: 0xE8
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
	ECLASS						SWETYP[1:0]	
Access	R						R	R
Reset	0						0	0

Bit	23	22	21	20	19	18	17	16
	WPVSRC[15:8]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	WPVSRC[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
					SWE	SEQE	CGD	WPVS
Access					R	R	R	R
Reset					0	0	0	0

Bit 31 – ECLASS Software Error Class (cleared on read)
0 (WARNING): An abnormal access that does not affect system functionality.
1 (ERROR): A write access is performed into PIT64B_MR, PIT64B_LSBR, PIT64B_MSBR while the PIT64B is running.

Bits 25:24 – SWETYP[1:0] Software Error Type (cleared on read)

Value	Name	Description
0	READ_WO	A write-only register has been read (warning).
1	WRITE_RO	A write access has been performed on a read-only register (warning).
2	UNDEF_RW	Access to an undefined address (warning).
3	WEIRD_ACTION	A write access is performed into PIT64B_MR, PIT64B_LSBR, PIT64B_MSBR while the PIT64B is running (abnormal).

Bits 23:8 – WPVSRC[15:0] Write Protection Violation Source
When WPVS=1, WPVSRC indicates the register address offset at which a write access has been attempted.
When WPVS=0 and SWE=1, WPVSRC reports the address of the incorrect software access. As soon as WPVS=1, WPVSRC returns the address of the write-protected violation.

Bit 3 – SWE Software Control Error (cleared on read)

Value	Description
0	No software error has occurred since the last read of PIT64B_WPSR.
1	A software error has occurred since the last read of PIT64B_WPSR. The field SWETYP details the type of software error; the associated incorrect software access is reported in the field WPVSRC (if WPVS=0).

Bit 2 – SEQE Internal Sequencer Error (cleared on read)

Value	Description
0	No peripheral internal sequencer error has occurred since the last read of PIT64B_WPSR.

Value	Description
1	A peripheral internal sequencer error has occurred since the last read of PIT64B_WPSR. This flag can only be set under abnormal operating conditions.

Bit 1 – CGD Clock Glitch Detected (cleared on read)

Value	Description
0	The clock monitoring circuitry has not been corrupted since the last read of PIT64B_WPSR. Under normal operating conditions, this bit is always cleared.
1	The clock monitoring circuitry has been corrupted since the last read of PIT64B_WPSR. This flag can only be set in case of abnormal clock signal waveform (glitch).

Bit 0 – WPVS Write Protection Violation Status (cleared on read)

Value	Description
0	No write protection violation has occurred since the last read of the PIT64B_WPSR.
1	A write protection violation has occurred since the last read of the PIT64B_WPSR. If this violation is an unauthorized attempt to write a protected register, the associated violation is reported into field WPVSRC.

29. Chip Identifier (CHIPID)

29.1 Description

Chip Identifier (CHIPID) registers are used to recognize the device and its revision. These registers provide the sizes and types of the on-chip memories, as well as the set of embedded peripherals.

Two CHIPID registers are embedded: Chip ID register (CHIPID_CIDR) and Chip ID Extension register (CHIPID_EXID). Both registers contain a hard-wired value that is read-only.

The CHIPID_CIDR register contains the following fields:

- VERSION: Identifies the revision of the silicon
- ID: Product identifier
- EXT: Shows the use of the extension identifier register

The CHIPID_EXID register is device-dependent and reads ‘0’ if CHIPID_CIDR.EXT = 0.

29.2 Embedded Characteristics

- Chip ID Registers
  – Identification of the device revision, sizes of the embedded memories, set of peripherals, embedded processor

Table 29-1. CHIPID Registers

Device Name	CHIPID_CIDR	CHIPID_EXID
SAMA7G54	0x8016211x	0x00000000

29.3 Register Summary

Offset	Name	Bit Pos.	7	6	5	4	3	2	1	0
0x00	CHIPID_CIDR	31:24	EXT				ID[22:19]			
		23:16	ID[18:11]							
		15:8	ID[10:3]							
		7:0	ID[2:0]			1	VERSION[3:0]			
0x04	CHIPID_EXID	31:24	EXID[31:24]							
		23:16	EXID[23:16]							
		15:8	EXID[15:8]							
		7:0	EXID[7:0]							

29.3.1 Chip ID Register

Name: CHIPID_CIDR
Offset: 0x0
Reset: 0x8016211x
Property: Read-only

Values not listed for bitfields must be considered as “reserved”

Bit	31	30	29	28	27	26	25	24
	EXT				ID[22:19]			
Access	R				R	R	R	R
Reset	x				x	x	x	x

Bit	23	22	21	20	19	18	17	16
	ID[18:11]							
Access	R	R	R	R	R	R	R	R
Reset	x	x	x	x	x	x	x	x

Bit	15	14	13	12	11	10	9	8
	ID[10:3]							
Access	R	R	R	R	R	R	R	R
Reset	x	x	x	x	x	x	x	x

Bit	7	6	5	4	3	2	1	0
	ID[2:0]			1	VERSION[3:0]			
Access	R	R	R	R	R	R	R	R
Reset	x	1	1	2	6	1	0	8

Bit 31 – EXT Extension Flag

Value	Description
0	Chip ID has a single register definition without extension.
1	An extended Chip ID exists.

Bits 27:5 – ID[22:0] Product ID

Bit 4 – 1 Must be ‘1’.

Bits 3:0 – VERSION[3:0] Version of the Device
Current version of the device.

29.3.2 Chip ID Extension Register

Name: CHIPID_EXID
Offset: 0x4
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
	EXID[31:24]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	EXID[23:16]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	EXID[15:8]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	EXID[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bits 31:0 – EXID[31:0] Chip ID Extension
This field is cleared if CHIPID_CIDR.EXT = 0.

30. OTP Memory Controller (OTPC)

30.1 Description

The OTP Memory Controller (OTPC) is the secure interface between the system and the OTP memory.

The default value of a memory bit is logic ‘0’ (not programmed). A programmed memory bit is logic ‘1’.

An OTP matrix is a type of non-volatile memory. Each bit in the matrix can be programmed only once. The bits are used to store data such as:

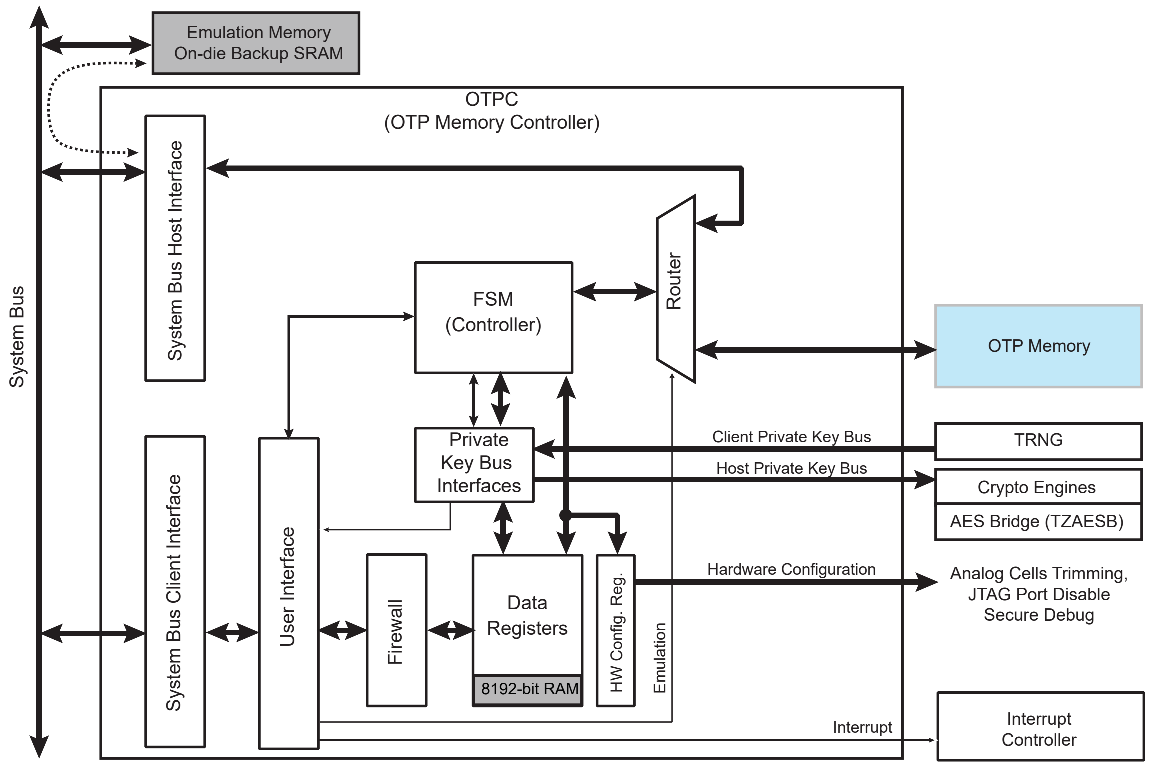
- calibration bits for analog cells (e.g. RC oscillators, etc.),
- hardware configuration settings (e.g. JTAG disable, etc.),
- chip identifiers,
- key data invisible by software,
- user data.

30.2 Embedded Characteristics

- Programs and Reads the Memory by Software
- Emulation Mode
- Automatic Check of Programmed Bits on Startup for Safe Operation
- User Area Organized by Packet for Flexibility on Size and Security:
  – Individual packet locking possibility (with checksum check)
  – Individual packet read access through only Private Key bus or System bus
  – Individual packet hiding (for packet with System bus access only)
  – Individual packet size of 32 bits to 8192 bits in 32-bit steps
  – Individual packet invalidation
- Firewall: Software/Hardware Protection Against Unexpected Read/Write

30.3 Block Diagram

Figure 30-1. OTPC Block Diagram



30.4 Product Dependencies

30.4.1 Power Management

The OTPC is clocked through the Power Management Controller (PMC), so the programmer must first to configure the PMC.

30.4.2 Interrupt Sources

The OTPC interface has an interrupt line connected to the Interrupt Controller.

Handling the OTPC interrupt requires programming the Interrupt Controller before configuring the OTPC.

30.5 Functional Description

30.5.1 Bus Interfaces

The OTPC features four bus interfaces to access the OTP memory:

- Host system bus
- Client system bus
- Host key bus (private key bus)
- Client key bus (private key bus)

The host system bus is used in Emulation mode to write and read data to/from the Emulation memory instead of the OTP memory. The host system bus can only access the emulation memory.

The client system bus is available to access to the user interface.

The host key bus is available to read keys stored in the User area of the OTP memory and transfer them to the client crypto-engines connected to this bus (e.g. AES, TZAESB). No data accessible to the host key bus are accessible to the System bus.

The client key bus is available to write some data to the User area of the OTP memory. No data coming from the client key bus are accessible to the system bus.

30.5.2 OTP Memory Partitioning

The OTP memory is partitioned into different areas:

- Reserved area
- 11-Kbyte User area

The initial value of the OTP memory is ‘0’ but the memory may contain some “defective” bits already set to the value ‘1’.

The memory is organized into 32-bit words.

30.5.3 User Area

30.5.3.1 Area Configuration and Control

The User area is controlled and configured through the OTPC Control (OTPC_CR), OTPC Mode (OTPC_MR) and OTPC Data (OTPC_DR) registers.

30.5.3.2 Area Mapping

The entire User area space is mapped into 32-bit words. Each 32-bit word is part of one packet.

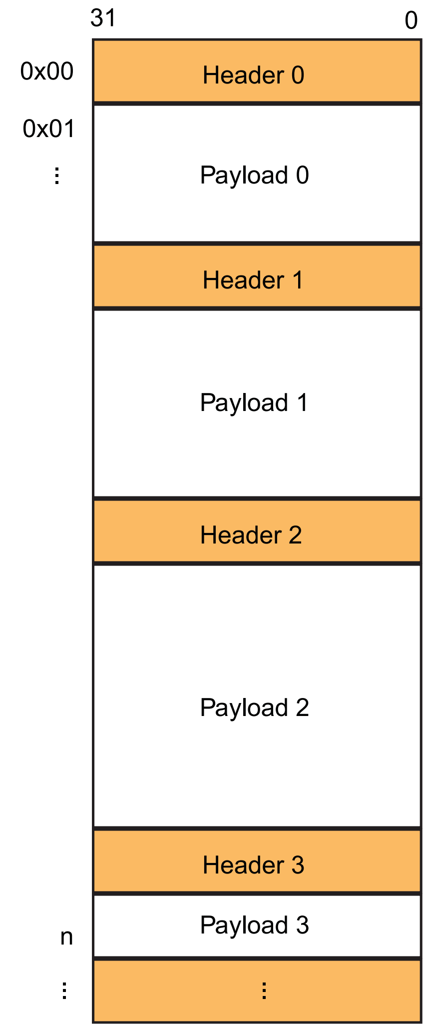
Each packet contains a 32-bit header and 32-bit words of payload (data). The number of payload words is defined in the header.

This mapping system allows three important functions for an OTP memory:

- Gives a flexible size for any type of data
- Improves security by identifying and masking key areas to the System bus,
- Provides an easy way to invalidate a packet and create a replacement packet (key, data) while free space is available in OTP.

The packet organization into the User area is shown in the figure below.

Figure 30-2. User Area Memory Mapping



The number of packets depends on the size of the User area and the size of each packet.

30.5.3.3 Packet Definition

Each packet contains:

- One 32-bit header field
- One payload field containing at least 32 bits of data and up to 256 x 32 bits of data (8192 bits)

The payload field has no effect on the hardware except for "special" packets.

30.5.3.3.1 Header Field

The following table provides the definition of the header content.

31	30	29	28	27	26	25	24
CHECKSUM							
23	22	21	20	19	18	17	16
CHECKSUM							
15	14	13	12	11	10	9	8
SIZE							
7	6	5	4	3	2	1	0

ONE	SECURE	INVLD	LOCK	PACKET

- PACKET: Indicates the packet type. Six types are available:
  - REGULAR packet (value 1) accessible through the User Interface
  - KEY packet (value 2) accessible only through the Private Key buses
  - BOOT_CONFIGURATION “special” packet (value 3)
  - SECURE_BOOT_CONFIGURATION “special” packet (value 4)
  - HARDWARE_CONFIGURATION “special” packet (value 5)
  - CUSTOM “special” packet (value 6)
- LOCK: Written by the controller when the checksum is generated.
- INVLD: Written when an invalidation process is requested.
- SECURE: Indicates if the packet must be available to the secure or non-secure domain. Also applies to the Key bus transfers.
- ONE: Must be written to ‘1’.
- SIZE: Indicates the size in 32-bit words of the payload field. SIZE = 0 means payload is 32-bit size, SIZE = 255 means payload is 8192-bit size.
  The entire packet size (in bits) in OTP memory is 32 (header) + (32 * (SIZE + 1)).
- CHECKSUM: Represents the checksum of the packet excluding the CHECKSUM field of the header. The real value of the CHECKSUM field is not readable; it is generated by the OTPC.
  - When CHECKSUM is read as 0, the checksum has not been generated. It is possible to modify the packet content.
  - When CHECKSUM is read as 0x33CC, the checksum has not been generated but some bits are already at 1. Locking the packet may fail.
  - When CHECKSUM is read as 0xA5A5, the checksum has been generated and the last check was successful. It is impossible to modify the packet content.
  - When CHECKSUM is read as 0xCC33, the header of the packet is corrupted.
  - When CHECKSUM is read as 0xFFFF, the entire packet is no longer valid. It is possible to modify the packet content and it is up to the software to program the payload to a different value if needed.
  - For all other values of CHECKSUM, the checksum has been generated and the last check failed to match the checksum written in the OTP memory. It is impossible to modify the packet content.

30.5.3.3.2 “Special” Packets

The payload of “special” packets is interpreted by the OTPC and some actions can be triggered while the “special” packets are read. The address of the “special” packets inside the area does not matter.

If the checksum has been generated and does not match during the last read, the payload is not interpreted by the OTPC.

The table below provides the list of “special” packets.

Table 30-1. “Special” Packets

Name	SIZE	PACKET	Description
Boot Configuration	(see Note 1)	3	Boot configuration
Secure Boot Configuration	(see Note 1)	4	Secure Boot configuration
User Hardware Configuration	1	5	Hardware configuration
Custom	N/A	6	For user custom purposes. The size of this packet is user application dependent.

Note:

1. For details, refer to the section “Boot Strategies”.

The address of the Boot Configuration and Secure Boot Configuration special packets can be retrieved in the OTPC Boot Addresses (OTPC_BAR) register.

The address of the Custom special packets can be retrieved in the OTPC Custom Address (OTPC_CAR) register for non-secure packets and in the OTPC Secure Custom Address (OTPC_SCAR) register for secure packets.

For each “special” packets, if there is more than one valid packet (of the same type), only the last packet will be considered (previous packets will be ignored). It is recommended to invalidate prior “special” packets to keep only one valid packet for each “special” packet type.

30.5.3.4 Init

After each reset, the OTPC parses the User area to check its content. The header of each packet will be read, depending on the header value some actions can be triggered:

- If the header is corrupted, the init sequence is interrupted and the OTPC_ISR.COERR bit is set.
- If the INVLD field of the header is 3, the OTPC ignores the packet and jumps to the next header.
- If the LOCK bit of the header is set, the payload is read and the checksum computed during the read is compared to the checksum saved in the header. If the checksums do not match, the OTPC_ISR.CKERR bit will be set.
- If the PACKET field of the header is BOOT_CONFIGURATION, the address of the packet will be stored in the OTPC_BAR.BCADDR field. Any previous value stored in the OTPC_BAR.BCADDR field is lost.
- If the PACKET field of the header is SECURE_BOOT_CONFIGURATION, the address of the packet will be stored in the OTPC_BAR.SBCADDR field. Any previous value stored in the OTPC_BAR.SBCADDR field is lost.
- If the PACKET field of the header is HARDWARE_CONFIGURATION, the payload is read and stored in the OTPC User Hardware Configuration (OTPC_UHCxR) registers (unless the checksums do not match if the packet is locked, in that case the reset value of the OTPC_UHCxR registers is stored). Any previous value stored in the OTPC_UHCxR registers is lost.
- If the PACKET field of the header is CUSTOM and the SECURE bit is 0, the address of the packet will be stored in the OTPC_CAR.CADDR field. Any previous value stored in the OTPC_CAR.CADDR field is lost.
- If the PACKET field of the header is CUSTOM and the SECURE bit is 1, the address of the packet will be stored in the OTPC_SCAR.SCADDR field. Any previous value stored in the OTPC_SCAR.SCADDR field is lost.

At the end of the init sequence, the value of the last HARDWARE_CONFIGURATION “special“ packet found is applied to the hardware.

30.5.3.5 Read Access

The User area can be read through the User interface at any time after a reset. Each packet is available through the OTPC_DR register. To trigger a packet read, follow the steps below:

1. The address of the header (or any address of the payload) must be written in OTPC_MR.ADDR.
2. OTPC_CR.READ must be set to ‘1’ (the OTPC_CR.KEY field value does not matter).
3. Wait for OTPC_ISR.EOR to be set to ‘1’ or for OTPC_SR.READ to be set to ‘0’, indicating that the whole packet has been transferred into temporary registers.
4. Read the header of the packet in the OTPC_HR register. To read each payload word, the address of the payload word must be written in OTPC_AR.DADDR. The payload word is then available in OTPC_DR. If OTPC_AR.INCRT is set to AFTER_READ, any read in the OTPC_DR increments the DADDR field.

   If INCRT is set to AFTER_WRITE, any write in the OTPC_DR increments the DADDR field.

The payload of a packet with PACKET set to KEY is read as ‘0’. The payload of a packet hidden since the last reset is read as ‘0’.

30.5.3.5.1 Transfer a Packet through the Host Key Bus

To transfer a packet from the OTP memory through the host key bus, follow the steps below:

1. The address of the header (or any address of the payload) must be written in OTPC_MR.ADDR. Only the packets with the packet type set to KEY are transferable on the host key bus.
2. The key bus destination must be written in OTPC_MR.KBDST.
3. Write 0x7167in the OTPC_CR.KEY field and ‘1’ to OTPC_CR.KBSTART.

The end of the transfer is indicated by OTPC_ISR.EOKT=’1’ and/or OTPC_SR.MKBB=’0’.

If the type of the packet is not KEY, OTPC_ISR.KBERR is set.

To cancel a packet transfer, OTPC_CR.KEY must be set to 0x7167 and KBSTOP must be set.

30.5.3.5.2 Hiding a Packet

For security reasons, it is possible to hide a packet after having read it through the User Interface. Once hidden, any read to the payload of the packet returns ‘0’.

To unhide a packet, a reset is necessary.

Hiding a packet does not make it available through the Key Buses.

To hide a packet, follow the steps below:

1. Write the address value of the header of the packet to hide in OTPC_MR.ADDR.
2. Write 0x7167 in OTPC_CR.KEY and ‘1’ to HIDE.

30.5.3.6 Write (Program) Considerations

Each word of the User area can be written only once. It is possible to write a packet payload partially and/or update a packet payload already written.

The packet to write (either the header or the payload) may contain some bits already at ‘1’. In this case, a dummy packet can be used to write the packet in a different location. The OTPC may also be able to fix the ‘1’ already written if this bit also matches the packet to write. Thus before writing any new packet, it is necessary to proceed to a read at the last address.

30.5.3.6.1 ‘1’ in the Header

After the read, the header may contain one or more ‘1’s. If the ‘1’s match the ‘1’s to write in the header, the packet can be written.

If the ‘1’s do not all match the ‘1’s to write in the header, the packet cannot be written. It is mandatory to create (and then invalidate if necessary) a packet with a compatible header.

30.5.3.6.2 ‘1’ in the Payload

If the payload is written and then updated later, the ‘1’s already written must match the ‘1’s to write.

If the payload is written only once (no update later), the ‘1’s already written must all match either the ‘1’ or the ‘0’ to write (it cannot be a mix of ‘1’s and ‘0’s to write).

30.5.3.7 Write (Program) Access

The User area can be programmed at any time after a reset until OTPC_MR.WRDIS has been set.

30.5.3.7.1 Writing a New Packet from the User Interface

To write a new packet from the User Interface, follow the steps below:

1. Write OTPC_MR.NPCKT to ‘0’ if it is set at ‘1’.
2. Write OTPC_MR.ADDR to its maximum value.
3. Write a ‘1’ to OTPC_CR.READ and wait for the read completion (OTPC_ISR.EOR=‘1’ when the read is completed).
4. Check there is no bit already set to ‘1’ in the OTPC_HR and OTPC_DR. The check for the data registers can be replaced by reading OTPC_SR.ONEF (if ONEF is set, at least one bit of the data registers is set to ‘1’).
   If the header or the payload of the packet already contains a 1, the new packet may need to be adapted.
5. Write OTPC_MR.ADDR to ‘0’ and set NPCKT.
   Depending on the contents of the temporary registers, an automatic flush can be triggered. If an automatic flush is started, OTPC_SR.FLUSH is set and OTPC_ISR.EOF is raised at the completion of the flush. It is mandatory to wait for the end of the flush.
6. Write the header value in OTPC_HR. The value of PACKET must not be the same as KEY.
7. Set DADDR to ‘0’.
8. Write the first data in the OTPC_DR register. To update the 32-bit data later (using the packet update), the OTPC_DR register must be set to 0.
9. Increment the DADDR field and write the next data in the OTPC_DR. Repeat this operation until all the data has been written.
   Skip the increment of DADDR if INCRT is set to AFTER_WRITE.
10. Write USER_KEY in the OTPC_CR.KEY field and ‘1’ to OTPC_CR.PGM.

Before the write operation in the OTP memory, the OTPC checks the consistency of the packet and that the packet does not overlap on any existing packet. In case of error, OTPC_ISR.WERR is set and the write operation is cancelled.

The end of the programming operation is indicated by OTPC_ISR.EOP=’1’ and/or OTPC_SR.PGM=’0’. At the end of the programming, the address of the header is available in OTPC_MR.ADDR and the OTPC_MR.NPCKT must be cleared.

The payload can be read back before programming. After read back, it is possible to update PACKET value to KEY before programming.

If the new written packet is the User Hardware Configuration special packet, its payload is ignored until the next reset or the next refresh. The OTPC_UHCxR registers will be updated after the reset or the refresh following programming.

30.5.3.7.2 Updating an Existing Packet from the User Interface

To update an existing packet from the User Interface, follow the steps below:

1. Write the address of the header of the packet to update in OTPC_MR.ADDR.
2. Start a read by setting OTPC_CR.READ and wait for the read completion indicated by OTPC_ISR.EOR.
3. Update the data using the OTPC_AR and OTPC_DR registers. Only the 32-bit data set to 0 can be updated, the non-zero 32-bit data must be left unchanged
4. Write 0x7167 in the OTPC_CR.KEY field and ‘1’ to OTPC_CR.PGM.

The end of the programming operation is indicated by OTPC_ISR.EOP='1' and/or OTPC_SR.PGM='0'.

If the updated packet is the User Hardware Configuration special packet, its new payload is ignored until the next reset. The OTPC_UHCxR registers will be updated after the reset or the refresh following programming.

30.5.3.7.3 Writing a Packet from the Client Key Bus

To write a packet from the client key bus interface (payload only), follow the steps below:

1. Write OTPC_MR.ADDR to ‘0’ and set NPCKT.
   Depending on the content of the temporary registers, an automatic flush can be triggered. If an automatic flush is started, OTPC_SR.FLUSH is set and OTPC_ISR.EOF is raised at the completion of the flush. It is mandatory to wait for the end of the flush.
2. Write the header value in the OTPC_HR register. The value of PACKET must be KEY.
3. Initiate a data transfer to the OTP memory through the TRNG host key bus.
4. Wait for the data transfer completion.
5. Check that no error happened during the key transfer (OTPC_ISR.KBERR must be cleared).
6. Write 0x7167 in the OTPC_CR.KEY field and ‘1’ to OTPC_CR.PGM.
7. Before the write operation in the OTP memory, the OTPC checks the consistency of the packet and that the packet does not overlap on any existing packet. In case of error, OTPC_ISR.WERR is set and the write operation is cancelled. The end of the programming operation is indicated by OTPC_ISR.EOP=1 and/or OTPC_SR.PGM=0.

If the PACKET field is changed before programming, the payload is erased (and lost).

30.5.3.7.4 Locking a Packet

To lock a packet, follow the steps below:

1. Write the address value of the header of the packet to lock in OTPC_MR.ADDR.
2. Start a read by setting OTPC_CR.READ and waiting for the read completion indicated by OTPC_ISR.EOR.
3. Write 0x7167 in the OTPC_CR.KEY field and ‘1‘ in OTPC_CR.CKSGEN.

The end of the lock operation is indicated by OTPC_ISR.EOL=’1’ and/or OTPC_SR.LOCK=’0’.

Generating the checksum locks the packet and modification is no longer possible.

30.5.3.7.5 Invalidating a Packet

To invalidate a packet, follow the steps below:

1. Write the address value of the header of the packet to invalidate in OTPC_MR.ADDR.
2. Write 0x7167 in the OTPC_CR.KEY field and ‘1’ to OTPC_CR.INVLD.

The end of the invalidation operation is indicated by OTPC_ISR.EOI= ‘1’ and/or OTPC_SR.INVLD=’0’.

If the invalidated packet is the User Hardware Configuration special packet, its old payload remains active until the next reset or the next refresh. The OTPC_UHCxR registers will be updated after the reset or the refresh following the invalidation operation.

30.5.3.8 Fixing Corruption

During a programming sequence, packet header corruption may occur. This corruption can be caused by a partial programming of the header. It is mandatory to fix any corruption prior to any usage of the Engineering Area or User Area.

During the start sequence, the OTPC stops parsing the OTP memory at the first header corruption detected. When OTPC_ISR.COERR is set, a corruption has been detected. The corrupted header can be read in OTPC_HR and its location can be read in OTPC_MR.ADDR.

A header is corrupted if at least one of the following statements matches:

- The ONE bit is cleared (it must be set to fix the corruption).
- The INVLD field is 3 and the PACKET field is 0 (PACKET must be set to a non-0 value to fix the corruption).
- The SIZE and PACKET fields are not consistent (for PACKET set to PRODUCT_UID, HARDWARE_CONFIGURATION or SECURITY_CONFIGURATION, the packet must be invalidated to fix the corruption).

To fix a corruption, start a a read procedure at the location of the corrupted header. The OTPC reads the payload according to the size provided in the header and reads one extra word of payload, which should match the next header.

The corrupted header must be fixed by writing any missing '1's or, if not possible, by extending its size if the supposed next header is 0, or by invalidating the packet.

A reset is required after fixing the corruption.

30.5.3.9 "Software" Protections

The User area can be protected against read accesses and/or modifications.

To enable read protection of the User data (OTPC_DR) and header (OTPC_HR) registers, OTPC_MR.RDDIS must be set. Clearing RDDIS allows read access again. When the OTPC_DR and OTPC_HR registers are read-protected, any read returns 0.

To enable write protection of the OTPC_DR registers, the WRDIS bit of OTPC_MR should be set. Clearing the WRDIS bit allows write access again.

To enable write protection of the User area, the write protection of the User data registers must be enabled.

The OTPC_MR can be locked until the next reset by setting the LOCK bit of OTPC_MR. Once locked, the current protection configuration of the OTPC_DR and OTPC_HR registers applies, it is then also impossible to update, program, invalidate, hide or read a packet (the OTPC_MR.ADDR field is then locked too preventing to select a packet).

30.5.3.10 "Hardware" Protections

The User area can be protected against read accesses and/or modifications.

To enable the different protections of the User area, the User Configuration special packet must be programmed. The packet is described in the OTPC_UHCxR registers.

As an example, to disable the JTAG interface for an indefinite period, the JTAGDIS, UHCINVDIS and UHCPGDIS fields of the User Hardware Configuration special packet must all be programmed to a non-zero value. Thus, it will be impossible to update or invalidate the User Hardware Configuration special packet.

⚠WARNING	"Hardware" protections are in effect for an indefinite period and cannot be cancelled.

30.5.4 OTP Emulation Mode

The OTPC features an Emulation mode. This Emulation mode can be used to test all the operations allowed by the controller on a backed-up memory instead of the real OTP memory.

When Emulation mode is enabled, the controller has the same behavior. The Emulation mode is enabled only when the OTP memory has not been previously programmed.

To enable/disable Emulation mode on the User area, follow the steps below:

1. Set OTPC_MR.EMUL to '1' (to enable) or to '0' (to disable).
2. Refresh the User area by writing a '1' to OTPC_CR.REFRESH and 0x7167 in OTPC_CR.KEY.
3. Wait for the refresh completion by polling OTPC_ISR.EORF.

The current running mode of the User area can be observed by reading OTPC_SR.EMUL. If EMUL is set to '1', Emulation mode is enabled; if it is set to '0', Emulation mode is disabled.

After a reset, Emulation mode is disabled.

30.5.5 Interrupts

An OTPC interrupt request can be triggered when one or several of the following bits are set in the OTPC Interrupt Status register (OTPC_ISR): End Of Programming (EOP), End Of Locking (EOL), End Of Invalidation (EOI), End Of Key Transfer (EOKT), Programming Error (PGERR), Locking Error (LKERR), Invalidation Error (IVERR), Write Error (WERR), End Of Read (EOR), End Of Flush (EOF), End Of Hide (EOH), End Of Refresh (EORF), Checksum Check Error (CKERR) or Key Invalid Error (KBERR).

The interrupt request is generated if the corresponding bit in the OTPC Interrupt Mask register (OTPC_IMR) is set. Bits in OTPC_IMR are set by writing a '1' to the corresponding bit in the OTPC Interrupt Enable register (OTPC_IER) and cleared by writing a '1' to the corresponding bit in the OTPC Interrupt Disable register (OTPC_IDR). The interrupt request remains active until the corresponding bit in OTPC_ISR is cleared.

Reading the OTPC_ISR clears all bits of the register.

30.5.6 Register Write Protection

To prevent any single software error from corrupting the OTPC behavior, certain registers in the address space can be write-protected by setting the Write Protection Configuration Enable (WPCFEN), Write Protection Interrupt Enable (WPITEN) and/or Write Protection Control Enable (WPCTEN) bit(s) in the Write Protection Mode Register (OTPC_WPMR).

If a write access to the protected registers is detected, the Write Protection Violation Status (WPVS) flag in the Write Protection Status Register (OTPC_WPSR) is set and the field Write Protection Violation Source (WPVSRC) indicates the register in which the write access has been attempted. An interrupt can be raised if the Security and/or Safety Event (SECE) interrupt is set in OTPC_IMR.

The WPVS flag is automatically reset by reading the OTPC_WPSR.

The following registers can be write-protected with the OTPC_WPMR.WPCFEN bit:

- OTPC Mode Register

The following registers can be write-protected with the OTPC_WPMR.WPITEN bit:

- OTPC Interrupt Enable Register
- OTPC Interrupt Disable Register

The following registers can be write-protected with the OTPC_WPMR.WPCTEN bit:

- OTPC Control Register

30.6 Register Summary

Offset	Name	Bit Pos.	7	6	5	4	3	2	1	0

30.6.1 OTPC Control Register

Name: OTPC_CR
Offset: 0x00
Reset: –
Property: Write-only

This register can only be written if the WPCTEN bit is cleared in the OTPC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
	KEY[15:8]							
Access	W	W	W	W	W	W	W	W
Reset	–	–	–	–	–	–	–	–

Bit	23	22	21	20	19	18	17	16
	KEY[7:0]							
Access	W	W	W	W	W	W	W	W
Reset	–	–	–	–	–	–	–	–

Bit	15	14	13	12	11	10	9	8
	REFRESH						KBSTOP	KBSTART
Access	W						W	W
Reset	–						–	–

Bit	7	6	5	4	3	2	1	0
	FLUSH	READ		HIDE		INVLD	CKSGEN	PGM
Access	W	W		W		W	W	W
Reset	–	–		–		–	–	–

Bits 31:16 – KEY[15:0] Programming Key
This field must be written with the correct key code (0x7167) to allow programming, checksum generation, packet invalidation or packet hiding.

Bit 15 – REFRESH Refresh the Area

Value	Description
0	No effect.
1	Starts a refresh of the area.

Bit 9 – KBSTOP Key Bus Transfer Stop

Value	Description
0	No effect.
1	Stops an on-going transfer on the host key bus.

Bit 8 – KBSTART Key Bus Transfer Start

Value	Description
0	No effect.
1	Starts a transfer through the host key bus.

Bit 7 – FLUSH Flush Temporary Registers

Value	Description
0	No effect.
1	Starts a flush of the temporary registers used to store the packet payload.

Bit 6 – READ Read Packet

Value	Description
0	No effect.
1	Starts a read sequence of the selected packet.

Bit 4 – HIDE Hide Packet

Value	Description
0	No effect.
1	The selected packet is not readable anymore until the next reset.

Bit 2 – INVLD Invalidate Packet

Value	Description
0	No effect.
1	Invalidates the selected packet.

Bit 1 – CKSGEN Generate Checksum

Value	Description
0	No effect.
1	Generates and programs the selected packet checksum. This action also locks the packet.

Bit 0 – PGM Program Packet

Value	Description
0	No effect.
1	The selected packet is written.

30.6.2 OTPC Mode Register

Name: OTPC_MR
Offset: 0x04
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPCFEN bit is cleared in the OTPC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
	ADDR[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	ADDR[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	LOCK		KBDST[1:0]				WRDIS	RDDIS
Access	R/W		R/W	R/W			R/W	R/W
Reset	0		0	0			0	0

Bit	7	6	5	4	3	2	1	0
	EMUL			NPCKT				UHCRRDIS
Access	R/W			R/W				R/W
Reset	0			0				0

Bits 31:16 – ADDR[15:0] Address
This field represents the address of the packet's header.

Bit 15 – LOCK Lock Register
The LOCK bit is set-only. Only a reset can disable lock.

Value	Description
0	The OTPC_MR register is unlocked; write access changes its value.
1	The OTPC_MR register is locked; write access does not change its value.

Bits 13:12 – KBDST[1:0] Key Bus Destination

Value	Name	Description
0	NONE	No destination selected (no transfer can occur).
1	AES	The AES is the destination of the key transfer.
2	TZAESB	The TrustZone AES Bridge is the destination of the key transfer.
3	TDES	The TDES is the destination of the key transfer.

Bit 9 – WRDIS Write Disable

Value	Description
0	The write capability of the OTPC_DR register is enabled.
1	The write capability of the OTPC_DR register is disabled.

Bit 8 – RDDIS Read Disable

Value	Description
0	The read capability of the OTPC_HR and OTPC_DR registers are enabled.
1	The read capability of the OTPC_HR and OTPC_DR registers are disabled. In case of read, the returned value is 0.

Bit 7 – EMUL Emulation Enable

Value	Description
0	The Emulation mode of the User area is disabled, all accesses are computed in the OTP memory.
1	The Emulation mode of the User area is enabled, all accesses are computed in the Emulation memory.

Bit 4 – NPCKT New Packet

Value	Description
0	Updates the packet defined at the ADDR address.
1	Creates a new packet.

Bit 0 – UHCRRDIS User Hardware Configuration Register Read Disable

Value	Description
0	The User Hardware Configuration register can be read through the User Interface.
1	The User Hardware Configuration register cannot be read through the User Interface.

30.6.3 OTPC Address Register

Name: OTPC_AR
Offset: 0x08
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
								INCRT
Access								R/W
Reset								0

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
	DADDR[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit 16 – INCRT Increment Type

Value	Name	Description
0	AFTER_READ	Increment DADDR after a read of OTPC_DR.
1	AFTER_WRITE	Increment DADDR after a write of OTPC_DR.

Bits 7:0 – DADDR[7:0] Data Address
This field represents the word address of the payload to access through the OTPC_DR register.

30.6.4 OTPC Status Register

Name: OTPC_SR
Offset: 0x0C
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
							ONEF	HIDE
Access							R	R
Reset							0	0

Bit	7	6	5	4	3	2	1	0
	FLUSH	READ	SKBB	MKBB	EMUL	INVLD	LOCK	PGM
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit 9 – ONEF One Found

Value	Description
0	No bit at ‘1’ found during the last packet read.
1	At least one ‘1’ has been found during the last packet read.

Bit 8 – HIDE Hiding On-Going

Value	Description
0	No packet hiding is on-going.
1	A packet hiding is on-going.

Bit 7 – FLUSH Flush On-Going

Value	Description
0	The temporary registers are not flushed.
1	The temporary registers are being flushed.

Bit 6 – READ Read On-Going

Value	Description
0	No packet read is on-going.
1	A packet read is on-going.

Bit 5 – SKBB Client Key Bus Busy

Value	Description
0	The client key bus is not busy.
1	The client key bus is busy.

Bit 4 – MKBB Host Key Bus Busy

Value	Description
0	The host key bus is not busy.

Value	Description
1	The host key bus is busy.

Bit 3 – EMUL Emulation Enabled

Value	Description
0	The User area Emulation mode is disabled.
1	The User area Emulation mode is enabled.

Bit 2 – INVLD Invalidation On-Going

Value	Description
0	No packet invalidation is on-going.
1	A packet invalidation is on-going.

Bit 1 – LOCK Lock On-Going

Value	Description
0	No packet locking is on-going.
1	A packet locking is on-going.

Bit 0 – PGM Programming On-Going

Value	Description
0	No packet programming is on-going.
1	A packet programming is on-going.

30.6.5 OTPC Interrupt Enable Register

Name: OTPC_IER
Offset: 0x10
Reset: –
Property: Write-only

This register can only be written if the WPITEN bit is cleared in the OTPC Write Protection Mode Register.

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Enables the corresponding interrupt.

Bit	31	30	29	28	27	26	25	24
				SECE				
Access				W				
Reset				–				

Bit	23	22	21	20	19	18	17	16
								KBERR
Access								W
Reset								–

Bit	15	14	13	12	11	10	9	8
		HDERR	COERR	CKERR	EORF	EOH	EOF	EOR

Access	W	W	W	W	W	W	W	W
Reset	–	–	–	–	–	–	–	–

Bit 28 – SECE Security and/or Safety Event Interrupt Enable

Bit 16 – KBERR Key Bus Error Interrupt Enable

Bit 14 – HDERR Hide Error Interrupt Enable

Bit 13 – COERR Corruption Error Interrupt Enable

Bit 12 – CKERR Checksum Check Error Interrupt Enable

Bit 11 – EORF End Of Refresh Interrupt Enable

Bit 10 – EOH End Of Hide Interrupt Enable

Bit 9 – EOF End Of Flush Interrupt Enable

Bit 8 – EOR End Of Read Interrupt Enable

Bit 7 – WERR Write Error Interrupt Enable

Bit 6 – IVERR Invalidation Error Interrupt Enable

Bit 5 – LKERR Locking Error Interrupt Enable

Bit 4 – PGERR Programming Error Interrupt Enable

Bit 3 – EOKT End Of Key Transfer Interrupt Enable

Bit 2 – EOI End Of Invalidation Interrupt Enable

Bit 1 – EOL End Of Locking Interrupt Enable

Bit 0 – EOP End Of Programming Interrupt Enable

30.6.6 OTPC Interrupt Disable Register

Name: OTPC_IDR
Offset: 0x14
Reset: –
Property: Write-only

This register can only be written if the WPITEN bit is cleared in the OTPC Write Protection Mode Register.

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Disables the corresponding interrupt.

Bit	31	30	29	28	27	26	25	24
				SECE				
Access				W				
Reset				–				

Bit	23	22	21	20	19	18	17	16
								KBERR
Access								W
Reset								–

Bit	15	14	13	12	11	10	9	8
		HDERR	COERR	CKERR	EORF	EOH	EOF	EOR

Access	W	W	W	W	W	W	W	W
Reset	–	–	–	–	–	–	–	–

Bit 28 – SECE Security and/or Safety Event Interrupt Disable

Bit 16 – KBERR Key Bus Error Interrupt Disable

Bit 14 – HDERR Hide Error Interrupt Disable

Bit 13 – COERR Corruption Error Interrupt Disable

Bit 12 – CKERR Checksum Check Error Interrupt Disable

Bit 11 – EORF End Of Refresh Interrupt Disable

Bit 10 – EOH End Of Hide Interrupt Disable

Bit 9 – EOF End Of Flush Interrupt Disable

Bit 8 – EOR End Of Read Interrupt Disable

Bit 7 – WERR Write Error Interrupt Disable

Bit 6 – IVERR Invalidation Error Interrupt Disable

Bit 5 – LKERR Locking Error Interrupt Disable

Bit 4 – PGERR Programming Error Interrupt Disable

Bit 3 – EOKT End Of Key Transfer Interrupt Disable

Bit 2 – EOI End Of Invalidation Interrupt Disable

Bit 1 – EOL End Of Locking Interrupt Disable

Bit 0 – EOP End Of Programming Interrupt Disable

30.6.7 OTPC Interrupt Mask Register

Name: OTPC_IMR
Offset: 0x18
Reset: 0x00000000
Property: Read-only

The following configuration values are valid for all listed bit names of this register:

0: Corresponding interrupt is not enabled.

1: Corresponding interrupt is enabled.

Bit	31	30	29	28	27	26	25	24
				SECE				
Access				R				
Reset				0				

Bit	23	22	21	20	19	18	17	16
								KBERR
Access								R
Reset								0

Bit	15	14	13	12	11	10	9	8

Bit 28 – SECE Security and/or Safety Event Interrupt Mask

Bit 16 – KBERR Key Bus Error Interrupt Mask

Bit 14 – HDERR Hide Error Interrupt Mask

Bit 13 – COERR Corruption Error Interrupt Mask

Bit 12 – CKERR Checksum Check Error Interrupt Mask

Bit 11 – EORF End Of Refresh Interrupt Mask

Bit 10 – EOH End Of Hide Interrupt Mask

Bit 9 – EOF End Of Flush Interrupt Mask

Bit 8 – EOR End Of Read Interrupt Mask

Bit 7 – WERR Write Error Interrupt Mask

Bit 6 – IVERR Invalidation Error Interrupt Mask

Bit 5 – LKERR Locking Error Interrupt Mask

Bit 4 – PGERR Programming Error Interrupt Mask

Bit 3 – EOKT End Of Key Transfer Interrupt Mask

Bit 2 – EOI End Of Invalidation Interrupt Mask

Bit 1 – EOL End Of Locking Interrupt Mask

Bit 0 – EOP End Of Programming Interrupt Mask

30.6.8 OTPC Interrupt Status Register

Name: OTPC_ISR
Offset: 0x1C
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
				SECE				
Access				R				
Reset				0				

Bit	23	22	21	20	19	18	17	16
								KBERR
Access								R
Reset								0

Bit	15	14	13	12	11	10	9	8
		HDERR	COERR	CKERR	EORF	EOH	EOF	EOR
Access		R	R	R	R	R	R	R
Reset		0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	WERR	IVERR	LKERR	PGERR	EOKT	EOI	EOL	EOP
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit 28 – SECE Security and/or Safety Event (cleared on read)

Value	Description
0	No security or safety event occurred since the last read of OTPC_ISR.
1	One or more safety or security event occurred since the last read of OTPC_ISR. For details on the event, refer to OTPC_WPSR.

Bit 16 – KBERR Key Bus Error (cleared on read)

Value	Description
0	No error happened on the key bus since the last read of OTPC_ISR.
1	An error happened on the key bus since the last read of OTPC_ISR.

Bit 14 – HDERR Hide Error (cleared on read)

Value	Description
0	No hiding error occurred since the last read of OTPC_ISR.
1	A hiding error occurred since the last read of OTPC_ISR.

Bit 13 – COERR Corruption Error (cleared on read)

Value	Description
0	No corruption occurred during the last start-up since the last read of OTPC_ISR.
1	A corruption occurred since the last read of OTPC_ISR.

Bit 12 – CKERR Checksum Check Error (cleared on read)

Value	Description
0	No checksum check failure occurred during last reading sequence since the last read of OTPC_ISR.
1	A checksum check failure occurred since the last read of OTPC_ISR.

Bit 11 – EORF End Of Refresh (cleared on read)

Value	Description
0	No refresh sequence completion since the last read of OTPC_ISR.
1	At least one refresh sequence completion since the last read of OTPC_ISR.

Bit 10 – EOH End Of Hide (cleared on read)

Value	Description
0	No hiding sequence completion since the last read of OTPC_ISR.
1	At least one hiding sequence completion since the last read of OTPC_ISR.

Bit 9 – EOF End Of Flush (cleared on read)

Value	Description
0	No flush of the temporary registers since the last read of OTPC_ISR.
1	At least one flush hof the temporary registers has been completed since the last read of OTPC_ISR.

Bit 8 – EOR End Of Read (cleared on read)

Value	Description
0	No reading sequence completion since the last read of OTPC_ISR.
1	At least one reading sequence completion since the last read of OTPC_ISR.

Bit 7 – WERR Write Error (cleared on read)

Value	Description
0	No write error occurred since the last read of OTPC_ISR.
1	A write error occurred since the last read of OTPC_ISR.

Bit 6 – IVERR Invalidation Error (cleared on read)

Value	Description
0	No invalidation failure occurred during last invalidation sequence since the last read of OTPC_ISR.
1	An invalidation failure occurred since the last read of OTPC_ISR.

Bit 5 – LKERR Locking Error (cleared on read)

Value	Description
0	No locking failure occurred during last locking sequence since the last read of OTPC_ISR.
1	A locking failure occurred since the last read of OTPC_ISR.

Bit 4 – PGERR Programming Error (cleared on read)

Value	Description
0	No programming failure occurred during last programming sequence since the last read of OTPC_ISR.
1	A programming failure occurred since the last read of OTPC_ISR.

Bit 3 – EOKT End Of Key Transfer (cleared on read)

Value	Description
0	No key transfer completion since the last read of OTPC_ISR.
1	At least one key transfer has been completed on the host key bus since the last read of OTPC_ISR.

Bit 2 – EOI End Of Invalidation (cleared on read)

Value	Description
0	No invalidation sequence completion since the last read of OTPC_ISR.
1	At least one invalidation sequence completion since the last read of OTPC_ISR.

Bit 1 – EOL End Of Locking (cleared on read)

Value	Description
0	No locking sequence completion since the last read of OTPC_ISR.
1	At least one locking sequence completion since the last read of OTPC_ISR.

Bit 0 – EOP End Of Programming (cleared on read)

Value	Description
0	No programming sequence completion since the last read of OTPC_ISR.
1	At least one programming sequence completion since the last read of OTPC_ISR.

30.6.9 OTPC Header Register

Name: OTPC_HR
Offset: 0x20
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
	CHECKSUM[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	CHECKSUM[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	SIZE[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	ONE	SECURE	INVLD[1:0]		LOCK	PACKET[2:0]		
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 31:16 – CHECKSUM[15:0] Packet Checksum
When CHECKSUM is read as 0, the checksum has not been generated. It is still possible to modify the packet content.
When CHECKSUM is read as 0x33CC, the checksum has not been generated but has already some bit at 1. Locking the packet may fail.
When CHECKSUM is read as 0xA5A5, the checksum has been generated and the last check was successful. It is impossible to modify the packet content.
When CHECKSUM is read as 0xCC33, the packet header is corrupted.
When CHECKSUM is read as 0xFFFF, the entire packet is no longer valid. It is possible to modify the packet content and it is up to the software to program the payload to a different value if needed.
For all other values of CHECKSUM, the checksum has been generated and the last check failed to match the checksum written in the OTP. It is impossible to modify the packet content.
This field is not writeable and is set by the OTPC during a lock request.

Bits 15:8 – SIZE[7:0] Packet Size
This field represents the size of the packet payload.
This field is writeable only for new packets.

Bit 7 – ONE One
This field is set to 1 by hardware and is not writeable.

Bit 6 – SECURE Secure Packet
This field is writeable only through accesses done in the secure world, otherwise it is set to 0.

Value	Description
0	The packet is not part of the secure world.
1	The packet is part of the secure world.

Bits 5:4 – INVLD[1:0] Invalid Status
If set to value 3, this field indicates that the packet is not valid.

This field is not writeable and is set by the OTPC during an invalidation request.

Bit 3 – LOCK Lock Status
This field is not writeable and is set by the OTPC during a lock request.

Value	Description
0	The packet is not locked.
1	The packet is locked.

Bits 2:0 – PACKET[2:0] Packet Type
This field is writeable only for new packets.

Value	Name	Description
1	REGULAR	Regular packet accessible through the user interface
2	KEY	Key packet accessible only through the Key Buses
3	BOOT_CONFIGURATION	Boot Configuration packet
4	SECURE_BOOT_CONFIGURATION	Secure Boot Configuration packet
5	HARDWARE_CONFIGURATION	Hardware Configuration packet
6	CUSTOM	Custom packet

30.6.10 OTPC Data Register

Name: OTPC_DR
Offset: 0x24
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
	DATA[31:24]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0
Bit	23	22	21	20	19	18	17	16
	DATA[23:16]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8
	DATA[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
	DATA[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 31:0 – DATA[31:0] Packet Data
This field represents the data of one of the packets. The data read or written is located at the address specified by OTPC_AR.DADDR.

30.6.11 OTPC Boot Addresses Register

Name: OTPC_BAR
Offset: 0x30
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
	SBCADDR[15:8]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
	BCADDR[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bits 31:16 – SBCADDR[15:0] Secure Boot Configuration Address
This field represents the address of the “Secure Boot Configuration” special packet.

Bits 15:0 – BCADDR[15:0] Boot Configuration Address
This field represents the address of the “Boot Configuration” special packet.

30.6.12 OTPC Custom Address Register

Name: OTPC_CAR
Offset: 0x34
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access

	JTAGDIS[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bits 15:8 – SECDBG[7:0] Secure Debug

Value	Description
0	The secure debug is allowed.
Non-Zero	The secure debug is forbidden.

Bits 7:0 – JTAGDIS[7:0] JTAG Disable

Value	Description
0	The JTAG is enabled.
Non-zero	The JTAG is disabled.

30.6.15 OTPC User Hardware Configuration 1 Register

Name: OTPC_UHC1R
Offset: 0x54
Reset: 0x00000000
Property: Read-only

Note: The reset value depends on hardware configuration.

Bit	31	30	29	28	27	26	25	24
Access

Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit 17 – URFDIS User Refresh Disable

Value	Description
0	The OTPC_CR.REFRESH bit is fully functional.
1	The OTPC_CR.REFRESH bit is only functional in Emulation mode.

Bit 16 – CPGDIS Custom Packet Program Disable

Value	Description
0	The programming of Custom Special Packet is allowed.
1	The programming of Custom Special Packet is forbidden.

Bit 15 – CLKDIS Custom Packet Lock Disable

Value	Description
0	The generation of the checksum (lock) of the Custom Special Packet is allowed.
1	The generation of the checksum (lock) of the Custom Special Packet is forbidden.

Bit 14 – CINVDIS Custom Packet Invalidation Disable

Value	Description
0	The invalidation of the Custom Special Packet is allowed.
1	The invalidation of the Custom Special Packet is forbidden.

Bit 13 – SCPGDIS Secure Custom Packet Program Disable

Value	Description
0	The programming of Secure Custom Special Packet is allowed.
1	The programming of Secure Custom Special Packet is forbidden.

Bit 12 – SCLKDIS Secure Custom Packet Lock Disable

Value	Description
0	The generation of the checksum (lock) of the Secure Custom Special Packet is allowed.

Value	Description
1	The generation of the checksum (lock) of the Secure Custom Special Packet is forbidden.

Bit 11 – SCINVDIS Secure Custom Packet Invalidation Disable

Value	Description
0	The invalidation of the Secure Custom Special Packet is allowed.
1	The invalidation of the Secure Custom Special Packet is forbidden.

Bit 10 – SBCPGDIS Secure Boot Configuration Packet Program Disable

Value	Description
0	The programming of Secure Boot Configuration Special Packet is allowed.
1	The programming of Secure Boot Configuration Special Packet is forbidden.

Bit 9 – SBCLKDIS Secure Boot Configuration Packet Lock Disable

Value	Description
0	The generation of the checksum (lock) of the Secure Boot Configuration Special Packet is allowed.
1	The generation of the checksum (lock) of the Secure Boot Configuration Special Packet is forbidden.

Bit 8 – SBCINVDIS Secure Boot Configuration Packet Invalidation Disable

Value	Description
0	The invalidation of the Secure Boot Configuration Special Packet is allowed.
1	The invalidation of the Secure Boot Configuration Special Packet is forbidden.

Bit 7 – BCPGDIS Boot Configuration Packet Program Disable

Value	Description
0	The programming of Boot Configuration Special Packet is allowed.
1	The programming of Boot Configuration Special Packet is forbidden.

Bit 6 – BCLKDIS Boot Configuration Packet Lock Disable

Value	Description
0	The generation of the checksum (lock) of the Boot Configuration Special Packet is allowed.
1	The generation of the checksum (lock) of the Boot Configuration Special Packet is forbidden.

Bit 5 – BCINVDIS Boot Configuration Packet Invalidation Disable

Value	Description
0	The invalidation of the Boot Configuration Special Packet is allowed.
1	The invalidation of the Boot Configuration Special Packet is forbidden.

Bit 4 – UHCPGDIS User Hardware Configuration Packet Program Disable

Value	Description
0	The programming of User Hardware Configuration Special Packet is allowed.
1	The programming of User Hardware Configuration Special Packet is forbidden.

Bit 3 – UHCLKDIS User Hardware Configuration Packet Lock Disable

Value	Description
0	The generation of the checksum (lock) of the User Hardware Configuration Special Packet is allowed.
1	The generation of the checksum (lock) of the User Hardware Configuration Special Packet is forbidden.

Bit 2 – UHCINVDIS User Hardware Configuration Packet Invalidation Disable

Value	Description
0	The invalidation of the User Hardware Configuration Special Packet is allowed.
1	The invalidation of the User Hardware Configuration Special Packet is forbidden.

Bit 1 – UPGDIS User programming Disable

Value	Description
0	The OTPC_CR.PGM bit is fully functional.

Value	Description
1	The OTPC_CR.PGM bit is not functional.

Bit 0 – URDDIS User Read Disable

Value	Description
0	The OTPC_CR.READ bit is fully functional.
1	The OTPC_CR.READ bit is not functional.

30.6.16 OTPC Product UID x Register

Name: OTPC_UIDxR
Offset: 0x60 + x*0x04 [x=0..3]
Reset: 0x00000000
Property: Read-only

Note: The reset value depends on hardware configuration.

Bit	31	30	29	28	27	26	25	24
	UID[31:24]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

	UID[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bits 31:0 – UID[31:0] Unique Product ID
This field represents the unique product ID.

30.6.17 OTPC Write Protection Mode Register

Name: OTPC_WPMR
Offset: 0xE4
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
	WPKEY[23:16]							
Access	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0
Bit	23	22	21	20	19	18	17	16
	WPKEY[15:8]							
Access	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8
	WPKEY[7:0]							
Access	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
				FIRSTE		WPCTEN	WPITEN	WPCFEN
Access				R/W		R/W	R/W	R/W
Reset				0		0	0	0

Bits 31:8 – WPKEY[23:0] Write Protection Key

Value	Name	Description
0x4F5450	PASSWD	Writing any other value in this field aborts the write operation. Always reads as 0.

Bit 4 – FIRSTE First Error Report Enable

Value	Description
0	The last write protection violation source is reported in OTPC_WPSR.WPVSRC and the last software control error type is reported in OTPC_WPSR.SWETYP; The OTPC_ISR.SECE flag is set at the first error occurrence within a series.
1	Only the first write protection violation source is reported in OTPC_WPSR.WPVSRC and only the first software control error type is reported in OTPC_WPSR.SWETYP. The OTPC_ISR.SECE flag is set at the first error occurrence within a series.

Bit 2 – WPCTEN Write Protection Control Enable

Value	Description
0	Disables the write protection of the control if WPKEY matches to 0x4F5450 (OTP in ASCII).
1	Enables the write protection of the control if WPKEY matches to 0x4F5450 (OTP in ASCII).

Bit 1 – WPITEN Write Protection Interrupt Enable

Value	Description
0	Disables the write protection of the interruption configuration if WPKEY matches to 0x4F5450 (OTP in ASCII).
1	Enables the write protection of the interruption configuration if WPKEY matches to 0x4F5450 (OTP in ASCII).

Bit 0 – WPCFEN Write Protection Configuration Enable

Value	Description
0	Disables the write protection of the configuration if WPKEY matches to 0x4F5450 (OTP in ASCII).
1	Enables the write protection of the configuration if WPKEY matches to 0x4F5450 (OTP in ASCII).

30.6.18 OTPC Write Protection Status Register

Name: OTPC_WPSR
Offset: 0xE8
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
	ECLASS				SWETYP[3:0]			
Access	R				R	R	R	R
Reset	0				0	0	0	0

Bit	23	22	21	20	19	18	17	16
	WPVSRC[15:8]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	WPVSRC[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
					SWE	SEQE	CGD	WPVS
Access					R	R	R	R
Reset					0	0	0	0

Bit 31 – ECLASS Software Error Class

Value	Name	Description
0	WARNING	An abnormal access that does not have any impact.
1	ERROR	An abnormal access that may have an impact.

Bits 27:24 – SWETYP[3:0] Software Error Type

Value	Name	Description
0	READ_WO	A write-only register has been read (warning).
1	WRITE_RO	A write access has been performed on a read-only register (warning).
2	CONF_CHG	A change has been made into the configuration (error).
3	KEY_ERROR	A write has been computed in OTPC_CR or OTPC_WPMR register with a wrong value in the related KEY field (error).
4	DATA_ACC	The non-secure world application tried to read a packet from the secure world (error).

Bits 23:8 – WPVSRC[15:0] Write Protection Violation Source
When WPVS = 1, WPVSRC indicates the register address offset at which a write access has been attempted.

Bit 3 – SWE Software Control Error (cleared on read)

Value	Description
0	No software error has occurred since the last read of OTPC_WPSR.
1	A software error has occurred since the last read of OTPC_WPSR. The field SWETYP details the type of software error encountered.

Bit 2 – SEQE Internal Sequencer Error (cleared on read)

Value	Description
0	No peripheral internal sequencer error has occurred since the last read of OTPC_WPSR.
1	A peripheral internal sequencer error has occurred since the last read of OTPC_WPSR. This flag can be set under abnormal operating conditions.

Bit 1 – CGD Clock Glitch Detected (cleared on read)

Value	Description
0	No clock glitch has occurred since the last read of OTPC_WPSR.
1	A clock glitch has occurred since the last read of OTPC_WPSR. This flag can be set under abnormal operating conditions.

Bit 0 – WPVS Write Protection Violation Status (cleared on read)

Value	Description
0	No write protection violation has occurred since the last read of OTPC_WPSR.
1	A write protection violation has occurred since the last read of OTPC_WPSR. If this violation is an unauthorized attempt to write a protected register, the associated violation is reported into WPVSRC.

31. Special Function Registers (SFR)

31.1 Description

Special Function Registers (SFR) manage specific aspects of the integrated memory, bridge implementations, processor and other functionality not controlled elsewhere.

31.2 Embedded Characteristics

- 32-bit Special Function Registers Control Specific Behavior of the Product

31.3 Functional Description

31.3.1 Register Write Protection

To prevent any single software error from corrupting SFR behavior, certain registers in the address space can be write-protected by setting the WPEN bit or the WPITEN bit in the SFR Write Protection Mode Register (SFR_WPMR).

If a write access to a write-protected register is detected, the WPVS flag in the SFR Write Protection Status Register (SFR_WPSR) is set and the field WPSRC indicates the register in which the write access has been attempted. To read this flag, the SFR peripheral clock must be enabled.

The WPVS bit is automatically cleared after reading the SFR_WPSR.

All registers can be write-protected by setting SFR_WPMR.WPEN.

31.4 Register Summary

Offset	Name	Bit Pos.	7	6	5	4	3	2	1	0
0x00	SFR_OHCIICR	31:24								
		23:16								
		15:8						SUSPEND2	SUSPEND1	SUSPEND0
		7:0							APPSTART	ARIE

31.4.1 OHCI Interrupt Configuration Register

Name: SFR_OHCIICR
Offset: 0x00
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
						SUSPEND2	SUSPEND1	SUSPEND0
Access						R/W	R/W	R/W
Reset						0	0	0

Bit	7	6	5	4	3	2	1	0
							APPSTART	ARIE
Access							R/W	R/W
Reset							0	0

Bits 8, 9, 10 – SUSPENDx USB PORT x

Value	Description
0	Suspends controlled by EHCI-OCHI.
1	Forces the suspend for PORTx.

Bit 1 – APPSTART Reserved
Must write ‘0’.

Bit 0 – ARIE OHCI Asynchronous Resume Interrupt Enable

Value	Description
0	Interrupt is disabled.
1	Interrupt is enabled.

31.4.2 OHCI Interrupt Status Register

Name: SFR_OHCIISR
Offset: 0x04
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
								WPEN
Access								R/W
Reset								0

Bits 31:8 – WPKEY[23:0] Write Protection Key

Value	Name	Description
0x534652	PASSWD	Writing any other value in this field aborts the write operation of the WPEN bit. Always reads as 0.

Bit 0 – WPEN Write Protection Enable
All registers are write-protected.

Value	Description
0	Disables the write protection if WPKEY value corresponds to 0x534652 (“SFR” in ASCII).
1	Enables the write protection if WPKEY value corresponds to 0x534652 (“SFR” in ASCII).

31.4.4 SFR Write Protection Status Register

Name: SFR_WPSR
Offset: 0xE8
Reset: 0x00000000
Property: Read-only

All registers can be write-protected.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
	WPSRC[15:8]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	WPSRC[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
								WPVS
Access								R
Reset								0

Bits 23:8 – WPSRC[15:0] Write Protection Source
When WPVS = 1, WPSRC indicates the register address offset at which a write access has been attempted.

Bit 0 – WPVS Write Protection Violation Status

Value	Description
0	No write protection violation has occurred since the last read of SFR_WPSR.
1	A write protection violation has occurred since the last read of SFR_WPSR. If this violation is an unauthorized attempt to write a protected register, the associated violation is reported into field WPSRC.

31.4.5 EHCIOHCI Register

Name: SFR_EHCIOHCI
Offset: 0x2020
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16

Bit 25 – VBUS VBUS Valid Indicator

Value	Description
0	The VBUS signal is not valid, and the pull-up resistor on D+ is disabled.
1	The VBUS signal is valid, and the pull-up resistor on D+ is enabled.

Bits 24:23 – TXPREEMPAMPTUNE[1:0] HS Transmitter Pre-Emphasis Current Control
Controls the amount of current sourced to HSS#_DP and HSS#_DM after a J-to-K or K-to-J transition. The HS Transmitter preemphasis current is defined in terms of unit amounts. One unit amount is approximately 600 μA and is defined as 1X pre-emphasis current.

Value	Name
00	HS Transmitter pre-emphasis is disabled (default).
01	HS Transmitter pre-emphasis circuit sources 1x pre-emphasis current (recommended).
10	HS Transmitter pre-emphasis circuit sources 2x pre-emphasis current.
11	HS Transmitter pre-emphasis circuit sources 3x pre-emphasis current.

Bit 3 – COMMONONN Common Block Power-Down Control

Value	Description
0	PLL blocks remain powered.
1	PLL blocks are powered down.

32. Special Function Registers Backup (SFRBU)

32.1 Description

Special Function Registers Backup (SFRBU) manages specific aspects of the integrated memory, bridge implementations, processor and other functionality not controlled elsewhere.

32.2 Embedded Characteristics

- 32-bit Special Function Registers Backup Controls Specific Behavior of the Product

32.3 Register Summary

Offset	Name	Bit Pos.	7	6	5	4	3	2	1	0

32.3.1 SFRBU Power Switch BU Control Register

Name: SFRBU_PSWBU
Offset: 0x00
Reset: 0x00000001
Property: Read/Write

The backup power switch selects the primary power source for the backup regulator (either VBAT or VDDIN33).

Bit	31	30	29	28	27	26	25	24
	PSWKEY[23:16]							
Access	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0
Bit	23	22	21	20	19	18	17	16
	PSWKEY[15:8]							
Access	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8
	PSWKEY[7:0]							
Access	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
						STATE	SOFTSWITCH	CTRL
Access						R	R/W	R/W
Reset						0	0	1

Bits 31:8 – PSWKEY[23:0] Specific Value Mandatory to Allow Writing of Other Register Bits (Write-only)
PSWKEY is a security key preventing power switch changes due to software error or malicious code.

Value	Name	Description
0x4BD20C	PASSWD	Writing any other value in this field aborts the write operation in the SFRBU_PSWBU register. Always reads as 0.

Bit 2 – STATE Power Switch BU State (Read-only)
Reflects the power switch BU supply source selection in real time. After a switching request, the user must wait for the analog cell switching time to have an updated status (see the section Electrical Characteristics).

Value	Name	Description
0	VBAT	LDO Supply source is VBAT.
1	VDDIN33	LDO Supply source is VDDIN33.

Bit 1 – SOFTSWITCH Power Switch BU Source Selection
Has an action only if CTRL is set to ‘1’.

Value	Name	Description
0	VBAT	LDO Supply source is VBAT.
1	VDDIN33	LDO Supply source is VDDIN33.

Bit 0 – CTRL Power Switch BU Control
Used to control the Power Switch BU state by software.

Value	Name	Description
0	HARD	Power Switch BU is controlled by hardware (SOFTSWITCH bit has no action).
1	SOFT	Power Switch BU is controlled by software (SOFTSWITCH bit has an action).

32.3.2 SFRBU 2.5V LDO Control Register

Name: SFRBU_LDO25CR
Offset: 0x0C
Reset: 0x00000001
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
	LDOANAKEY[23:16]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0
Bit	23	22	21	20	19	18	17	16
	LDOANAKEY[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8
	LDOANAKEY[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
					STATE	LOWPOWER	PD_VALUE[1:0]	
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	1

Bits 31:8 – LDOANAKEY[23:0] Specific value mandatory to allow writing of other register bits.
LDOANAKEY is a security key preventing power switch changes due to software error or malicious code.

Value	Name	Description
0x3B6E18	PASSWD	Writing any other value in this field aborts the write operation in the SFRBU_LDO25CR register. Always reads as 0.

Bit 3 – STATE LDOANA Switch On/Off Control

Value	Name	Description
0	ON	Switches LDOANA on.
1	OFF	Switches LDOANA off.

Bit 2 – LOWPOWER LDOANA Low-Power Mode Control

Value	Name	Description
0	NOT_SET	Switches LDOANA Low-power mode off.
1	SET	Switches LDOANA Low-power mode on.

Bits 1:0 – PD_VALUE[1:0] LDOANA Pull-down Value
LDOANA pull-down value plugged on LDO output when off.

Value	Name	Description
0	NONE	No pull-down plugged on LDO output when off.
1	500_OHMS	500 Ohms pull-down plugged on LDO output when off.
2	200_OHMS	200 Ohms pull-down plugged on LDO output when off.
3	100_OHMS	100 Ohms pull-down plugged on LDO output when off.

32.3.3 SFRBU DDR Power Control Register

Name: SFRBU_DDRPWR
Offset: 0x10
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
								RETENTION
Access								R/W
Reset								0

Bit 0 – RETENTION SDRAM I/Os Retention
When set, SDRAM I/Os are in Retention state. Refer to “Backup with SDRAM in Self-Refresh (BSR) Mode” in the section “Electrical Characteristics” for more details.

33. Slow Clock Controller (SCKC)

33.1 Description

The System Controller embeds a Slow Clock Controller (SCKC). The SCKC selects the slow clock for the RTT and the RTC from one of two sources:

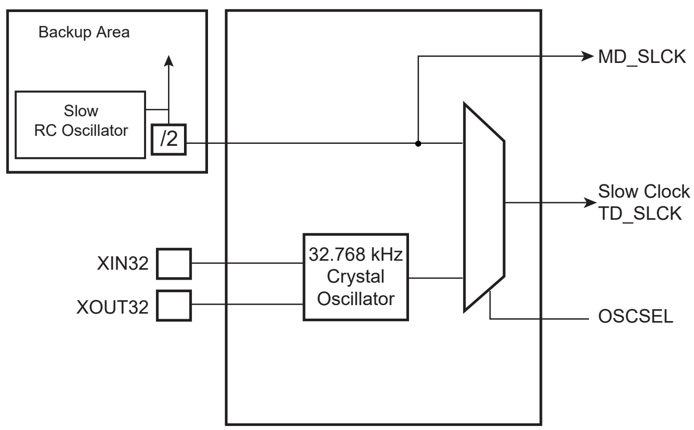
- External 32.768 kHz crystal oscillator
- Embedded always-on 64 kHz (typical) slow RC oscillator

33.2 Embedded Characteristics

- Always-on 64 kHz (Typical) Slow RC Oscillator or 32.768 kHz Crystal Oscillator Selector
- VDDBU-Powered

33.3 Block Diagram

Figure 33-1. SCKC Block Diagram



33.4 Functional Description

The TD_OSCSEL bit located in the Slow Clock Controller Configuration register (SCKC_CR) is in the backup domain and its value is kept while VBAT is present.

The embedded always-on 64 kHz (typical) slow RC oscillator is always enabled as soon as VBAT is established. The Slow Clock Selector command TD_OSCSEL bit selects the slow clock source of the RTT and the RTC.

After the VBAT Power-On-Reset, the default configuration is TD_OSCSEL = 0.

The programmer controls the slow clock switching by software, so precautions must be taken during the switching phase.

33.4.1 Switching from Embedded Always-on 64 kHz RC Oscillator to 32.768 kHz Crystal Oscillator

The sequence to switch from the embedded always-on 64 kHz (typical) slow RC oscillator to the 32.768 kHz crystal oscillator is the following:

1. Switch the main system bus clock to a source different from slow clock (PLL or Main Oscillator) through the Power Management Controller.
2. Switch from the embedded always-on 64 kHz RC oscillator to the 32.768 kHz crystal oscillator by writing a 1 to the TD_OSCSEL bit.

3. Wait 5 slow clock cycles for internal resynchronization.

33.4.2 Switching from 32.768 kHz Crystal Oscillator to Embedded Always-on 64 kHz RC Oscillator

The sequence to switch from the 32.768 kHz crystal oscillator to the embedded always-on 64 kHz (typical) RC oscillator is the following:

1. Switch the main system bus clock to a source different from slow clock (PLL or Main Oscillator).
2. Switch from the 32.768 kHz crystal oscillator to the embedded RC oscillator by writing a 0 to the TD_OSCSEL bit.
3. Wait 5 slow clock cycles for internal resynchronization.

33.5 Register Summary

Offset	Name	Bit Pos.	7	6	5	4	3	2	1	0
0x00	SCKC_CR	31:24								TD_OSCSEL
		23:16								
		15:8								
		7:0								

33.5.1 Slow Clock Controller Configuration Register

Name: SCKC_CR
Offset: 0x0
Reset: 0x00000001
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode register (SYSC_WPMR).

Bit	31	30	29	28	27	26	25	24
								TD_OSCSEL

Bit 24 – TD_OSCSEL Timing Domain Slow Clock Selector

Value	Description
`0 (RC)`	Slow clock of the timing domain is driven by the embedded always-on 64 kHz (typical) RC oscillator.
`1 (XTAL)`	Slow clock of the timing domain is driven by the 32.768 kHz crystal oscillator.

34. Clock Generator

34.1 Description

The Clock Generator user interface is embedded within the Power Management Controller and is described in the Register Summary. However, the Clock Generator registers are named CKGR_.

34.2 Embedded Characteristics

The Clock Generator is made up of:

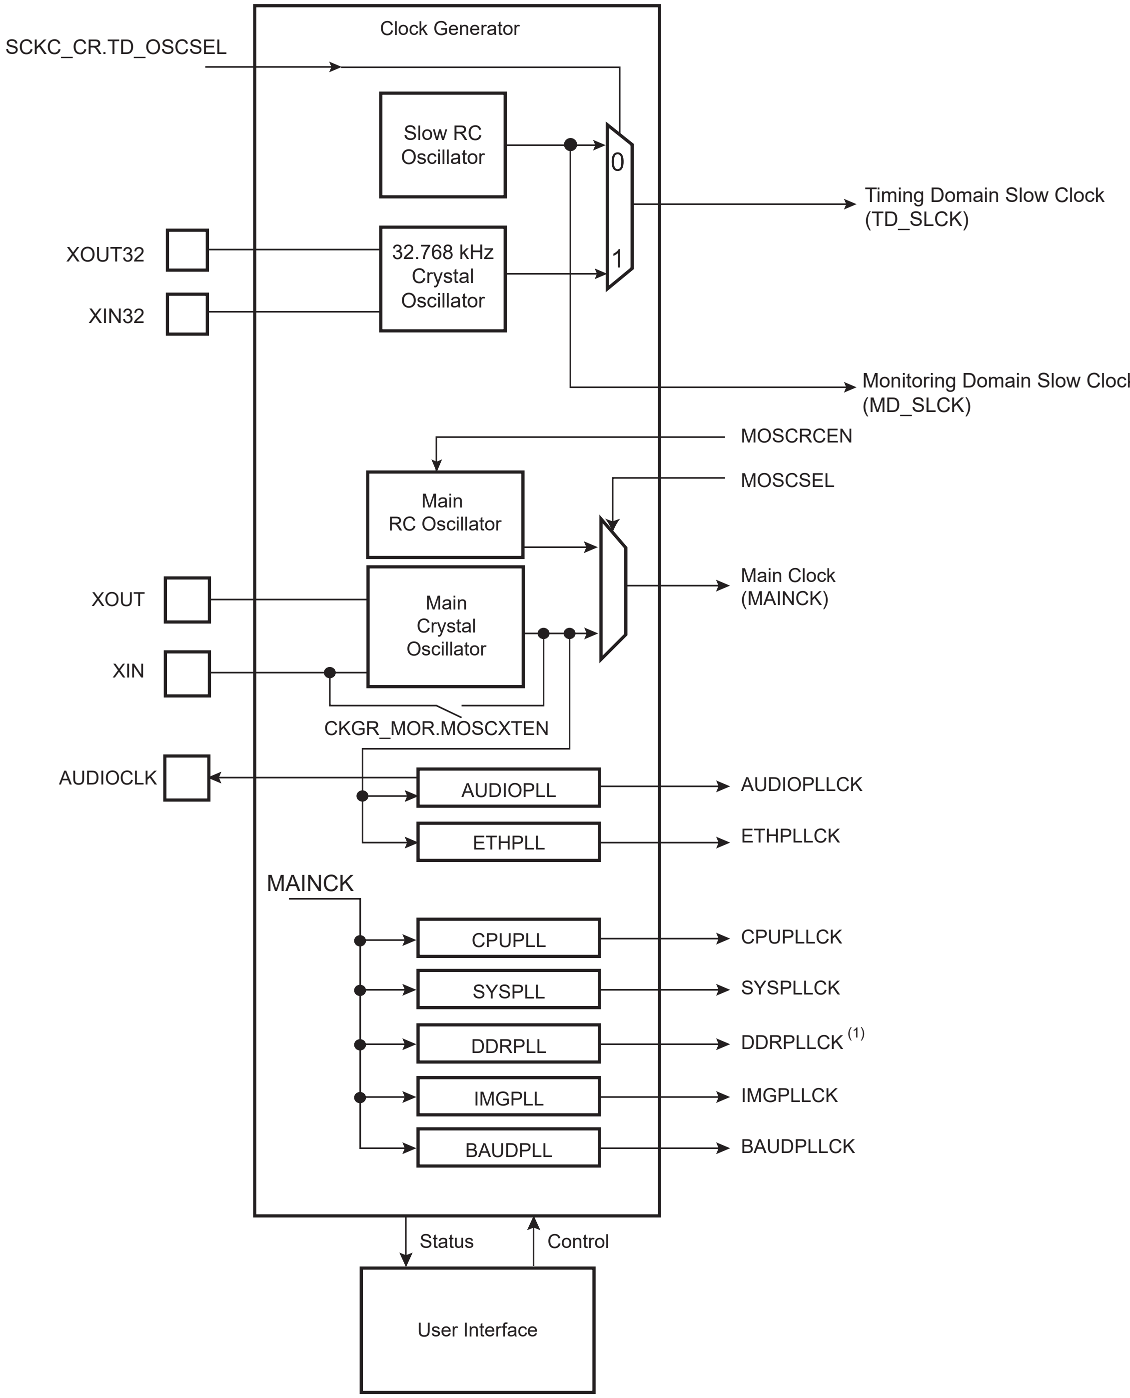
- Oscillators
  - A low-power 32.768 kHz oscillator supporting crystals and resonators (referred to as “32.768 KHz crystal oscillator” throughout the document)
  - An embedded always-on, slow RC oscillator generating a typical 32 kHz clock
  - A 12 to 50 MHz oscillator supporting crystals, resonators and Bypass mode (referred to as “main crystal oscillator” throughout the document)
  - A main RC oscillator generating a typical 12 MHz clock
- A set of 7 fractional-N PLLs with an input frequency range of 12 to 50 MHz and an internal frequency range of 600 to 1200 MHz, namely:
  - CPUPLL - PLL ID0
  - SYSPLL - PLL ID1
  - DDRPLL - PLL ID2
  - IMGPLL - PLL ID3
  - BAUDPLL - PLL ID4
  - AUDIOPLL - PLL ID5
  - ETHPLL - PLL ID6

The Clock Generator provides the following clocks:

- MD_SLCK—Monitoring domain slow clock. This clock, sourced from the always-on slow RC oscillator only, is the only permanent clock of the system and feeds safety-critical functions of the device (WDT, RSTC, SCKC, frequency monitors and detectors, PMC start-up time counters).
- TD_SLCK—Timing domain slow clock. This clock, sourced from the 32.768 kHz crystal oscillator or the always-on slow RC oscillator, is routed to the RTC and RTT peripherals.
- MAINCK—Output of the main clock oscillator selection. This clock is either the main crystal oscillator or the main RC oscillator.
- PLL Clocks—Outputs of embedded PLLs

34.3 Block Diagram

Figure 34-1. Clock Generator Block Diagram



Note (1) DDRPLLCK is hard-wired to the DDR subsystem (MCK2).

34.4 Slow Clock

The PMC does not control the slow clock generation. The control of the slow clock is performed by the Slow Clock Controller (SCKC) which embeds a slow clock generator that is supplied with the VDDBU power supply. As soon as VDDBU is supplied, both the 32.768 kHz crystal oscillator and the slow RC oscillator are powered, but only the slow RC oscillator is enabled.

MD_SLCK is always generated by the slow RC oscillator.

TD_SLCK is generated either by the 32.768 kHz crystal oscillator or by the slow RC oscillator.

The TD_SLCK source clock selection is made via the TD_OSCSEL bit in the Slow Clock Controller Configuration register (SCKC_CR).

34.4.1 Slow RC Oscillator (32 kHz typical)

The slow RC oscillator is a permanent clock that is the source clock of MD_SLCK and the default source clock of TD_SLCK.

Compared to the 32.768 kHz crystal oscillator, this oscillator offers a faster start-up time and is less exposed to the external environment, as it is fully integrated. However, its output frequency is subject to larger variations with supply voltage, temperature and manufacturing process. Therefore, the user must take these variations into account when this oscillator is used as a time base (start-up counter, frequency monitor, etc.). Refer to the section “Electrical Characteristics”.

34.4.2 32.768 kHz Crystal Oscillator

By default, the 32.768 kHz oscillator is enabled. To use this oscillator, the XIN32 and XOUT32 pins must be connected to a 32.768 kHz crystal or to a ceramic resonator. Refer to the section “Electrical Characteristics” for appropriate loading capacitors selection on XIN32 and XOUT32.

To select the 32.768 kHz crystal oscillator as the source of TD_SLCK, SCKC_CR.TD_OSCSEL must be set. This results in a sequence which first configures the PIO lines multiplexed with XIN32 and XOUT32 and driven by the crystal oscillator, and then enables the 32.768 kHz crystal oscillator. The switch of TD_SLCK source is glitch-free.

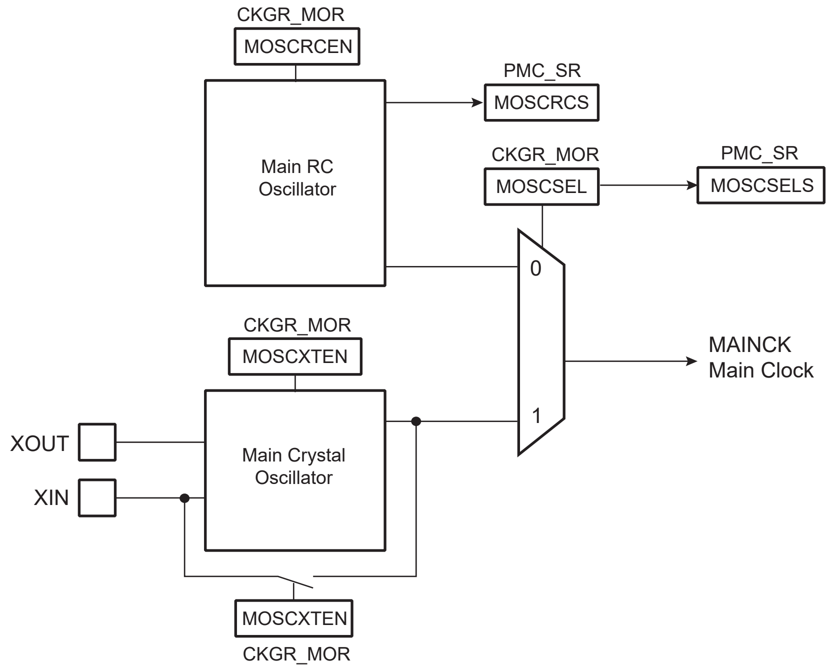
Reverting to the slow RC oscillator is only possible by shutting down the VDDBU power supply.

34.5 Main Clock

The main clock (MAINCK) has two sources:

- A main RC oscillator with a fast start-up time and that is selected by default to start the system
- A main crystal oscillator with Bypass mode

Figure 34-2. Main Clock (MAINCK) Block Diagram



34.5.1 Main RC Oscillator

After reset, the main RC oscillator is enabled. This oscillator is selected as the source of MAINCK. MAINCK is the default clock selected to start the system.

The main RC oscillator is calibrated in production. For output frequency specifications, refer to the section “Electrical Characteristics”.

The software can disable or enable the main RC oscillator with the MOSCRCEN bit in the Clock Generator Main Oscillator register (CKGR_MOR).

When disabling the main RC oscillator by clearing the CKGR_MOR.MOSCRCEN bit, the PMC_SR.MOSCRCS bit is automatically cleared, indicating that the oscillator is off.

Setting the MOSCRCS bit in the Power Management Controller Interrupt Enable Register (PMC_IER) triggers an interrupt to the processor.

34.5.2 Main Crystal Oscillator

After reset, the main crystal oscillator is disabled and is not selected as the source of MAINCK.

The software enables or disables this oscillator in order to reduce power consumption via CKGR_MOR.MOSCXTEN.

When disabling this oscillator by clearing CKGR_MOR.MOSCXTEN, the PMC_SR.MOSCXTS status bit is automatically cleared, indicating the oscillator is off. To activate the Main Crystal Oscillator Bypass mode, see Bypassing the Main Crystal Oscillator.

When enabling this oscillator, the user must initiate the start-up time counter. The start-up time depends on the characteristics of the external device connected to this oscillator.

When CKGR_MOR.MOSCXTEN and CKGR_MOR.MOSCXTST are written to enable this oscillator, XIN and XOUT are driven by the main crystal oscillator. PMC_SR.MOSCXTS is cleared and the counter starts counting down on MD_SLCK divided by 8 from the CKGR_MOR.MOSCXTST value. Since the CKGR_MOR.MOSCXTST value is coded with 8 bits, the start-up time can be programmed up to 2048 MD_SLCK periods, corresponding to about 62 ms when running at 32.768 kHz.

When the start-up time counter reaches ‘0’, PMC_SR.MOSCXTS is set, indicating that the oscillator is stabilized. Setting the MOSCXTS bit in the Interrupt Mask Register (PMC_IMR) can trigger an interrupt to the processor.

34.5.3 Main Clock Source Selection

The source of MAINCK can be selected from the following:

- the main RC oscillator
- the main crystal oscillator
- an external clock signal provided on the XIN input (Bypass mode of the main crystal oscillator)

The advantage of the main RC oscillator is its fast start-up time. By default, this oscillator is selected to start the system and it must be selected prior to entering ULP1 or ULP2 mode.

The advantage of the main crystal oscillator is its high level of accuracy.

The selection of the oscillator is made by configuring CKGR_MOR.MOSCSEL. The switchover of the MAINCK source is glitch-free, thus the switchover can be performed even if MCK0 is fed by MAINCK. PMC_SR.MOSCSELS indicates when the switch sequence is done.

Setting PMC_IMR.MOSCSELS triggers an interrupt to the processor.

34.5.4 Bypassing the Main Crystal Oscillator

Prior to bypassing the main crystal oscillator, the XOUT pin must be grounded and the external clock frequency provided on the XIN pin must be stable and within the values specified in the XIN Clock characteristics in the section “Electrical Characteristics”. Then the main crystal oscillator must be enabled by setting the CKGR_MOR.MOSCXTEN bit to 1.

34.5.5 Main Frequency Counter

The main frequency counter measures the main RC oscillator or the main crystal oscillator against the MD_SLCK and is managed by CKGR_MCFR.

During the measurement period, the main frequency counter increments at the speed of the clock defined by the bit CKGR_MCFR.CCSS.

A measurement is started in the following cases:

- When CKGR_MCFR.RCMEAS is written to ‘1’.
- When the main RC oscillator is selected as the source of MAINCK and when this oscillator is stable (i.e., when the MOSCRCS bit is set)
- When the main crystal oscillator is selected as the source of MAINCK and when this oscillator is stable (i.e., when the MOSCXTS bit is set)
- When MAINCK source selection is modified

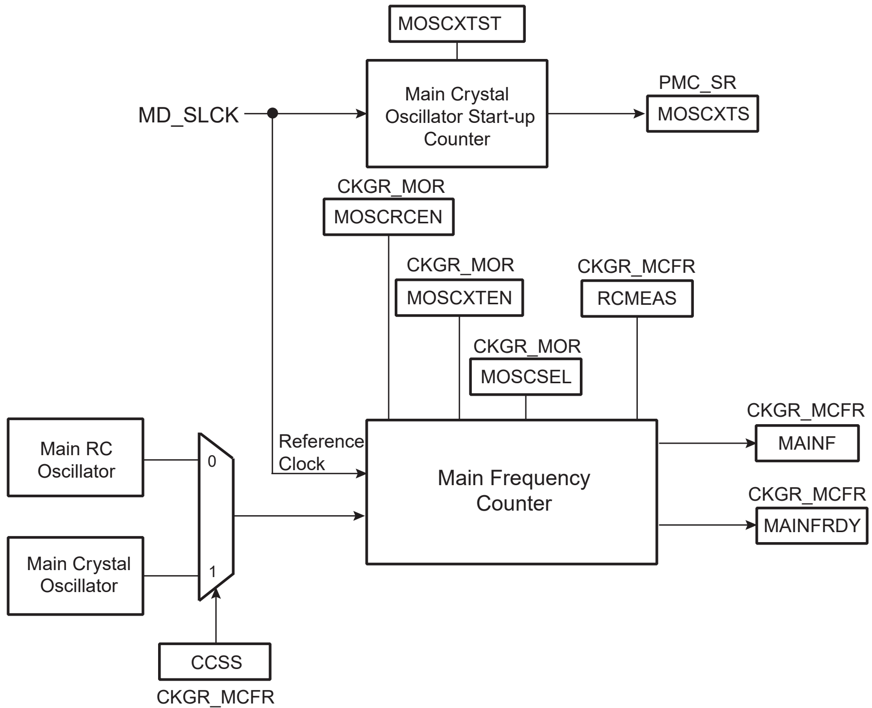
The measurement period ends at the 16th falling edge of MD_SLCK, the MAINFRDY bit in CKGR_MCFR is set and the counter stops counting. Its value can be read in the MAINF field of CKGR_MCFR and gives the number of clock cycles during 16 periods of MD_SLCK, so that the frequency of the main RC oscillator or main crystal oscillator can be determined.

When switching the source of MAINCK from the main RC oscillator to the main crystal oscillator, follow the programming sequence below to ensure that the oscillator is present and that its frequency is valid:

1. Enable the main crystal oscillator by setting CKGR_MOR.MOSCXTEN. Configure the CKGR_MOR. MOSCXTST field with the main crystal oscillator start-up time as defined in the section “Electrical Characteristics”.
2. Wait for PMC_SR.MOSCXTS flag to rise, indicating the end of a start-up period of the main crystal oscillator.
3. Select the main crystal oscillator as the source clock of the main frequency counter by setting CKGR_MCFR.CCSS.
4. Initiate a frequency measurement by setting CKGR_MCFR.RCMEAS.
5. Read CKGR_MCFR.MAINFRDY until its value equals 1.
6. Read CKGR_MCFR.MAINF and compute the value of the main crystal frequency.

If the MAINF value is valid, software can switch MAINCK to the main crystal oscillator. See Main Clock Source Selection.

Figure 34-3. Main Frequency Counter Block Diagram



34.6 PLL Controls

The PMC embeds 7 PLLs that are controlled by the PMC_PLL_CTRL0, PMC_PLL_CTRL1, PMC_PLL_SSR, PMC_PLL_ACR and PMC_PLL_UPDATE registers. Each PLL is accessed in read or write through its index as defined in the table below, corresponding to the register field PMC_PLL_UPDT.ID. At any time, PLL_CTRL0, PLL_CTRL1 and PLL_ACR reflect the controls for the PLL with index PMC_PLL_UPDT.ID. When the UPDATE bit is set in PMC_PLL_UPDT, the PLL of index PMC_PLL_UPDT.ID is updated with the content of registers PLL_CTRL0, PLL_CTRL1 and PLL_ACR.

Although these PLLs are identical, their implementations differ in terms of input clock signal, maximum output clock frequency or availability of a dedicated output line.

Each PLL is fed by either the MAINCK or the main crystal oscillator and has a constraint on the frequency it can generate on its clock output. Refer to the section “Electrical Characteristics”.

The table below describes all PLLs with their names and source clocks. For maximum frequency, refer to the section “Electrical Characteristics”.

Table 34-1. PLL IDs

Index	PLL Name	Clock Name	PLL Clock Source	Usage Example	IO PLL Clock
0	CPUPLL	CPUPLLCK	MAINCK	CPU clock source	–
1	SYSPLL	SYSPLLCK	MAINCK	MCK1 clock source (matrixes, etc.)	–
2	DDRPLL	DDRPLLCK	MAINCK	Clock source (DDR Phy)	–
3	IMGPLL	IMGPLLCK	MAINCK	MCK3 clock source (Image subsystem)	–
4	BAUDPLL	BAUDPLLCK	MAINCK	GCLK source for FLEXCOM, SDMMC, etc.	–

...........continued					
Index	**PLL Name**	**Clock Name**	**PLL Clock Source**	**Usage Example**	**IO PLL Clock**
5	AUDIOPLL	AUDIOPLLCK	MAIN XTAL OSC	AUDIOCLK output clock source	AUDIO_CLK
6	ETHPLL	ETHPLLCK	MAIN XTAL OSC	GMAC GCLK clock source	–

34.6.1 Divider and Phase Lock Loop Programming

Each PLL is controlled the same way. The internal clock frequency is configured by setting PMC_PLL_CTRL1.MUL and PMC_PLL_CTRL1.FRACR, then two division ratios are applied on the internal PLL clock:

- The first division ratio generates the PLL clock for the PMC.
- The second division ratio generates a clock for a dedicated output line (IOPLLCKx). This feature generates an output clock signal with improved jitter performance. It is not available for all PLLs. Refer to PLL Characteristics in the section “Electrical Characteristics” for more information.

The COREPLLCK operating frequency is defined as:

$$f_{\mathrm{COREPLLCK}} = f_{\mathrm{ref}}\left(\mathrm{MUL} + 1 + \frac{\mathrm{FRACR}}{2^{22}}\right)$$

The PLL clock frequency is defined by the following formula:

$$f_{\mathrm{PLL\ Clock}} = \frac{f_{\mathrm{COREPLLCK}}}{(\mathrm{DIVPMC} + 1)}$$

The IOPLLCK frequency is defined by the following formula:

$$f_{\mathrm{IOPLLCK}} = \frac{f_{\mathrm{COREPLLCK}}}{(\mathrm{DIVIO}+1)}$$

Each PLL sends a lock signal to the PMC to indicate its lock status. Once the lock signal has risen, the clock generated by the PLL is stable and can be sent to the PMC and/or its corresponding I/O if available.

This signal reports the lock status of the PLL by setting the corresponding PMC_PLL_CTRL0.ENLOCK to ‘1’.

If the lock status is disabled, a start-up time can be used instead in the PMC_PLL_UPDT register. The start-up time is expressed as a number of MD_SLCK cycles. Once the counter has reached the specified value, a flag rises. The start-up time field can only be written while all PLLs are disabled (i.e., their PLLEN fields are null).

If both a start-up time and the lock are enabled, the lock sent by the PLL is read once the start-up time has elapsed.

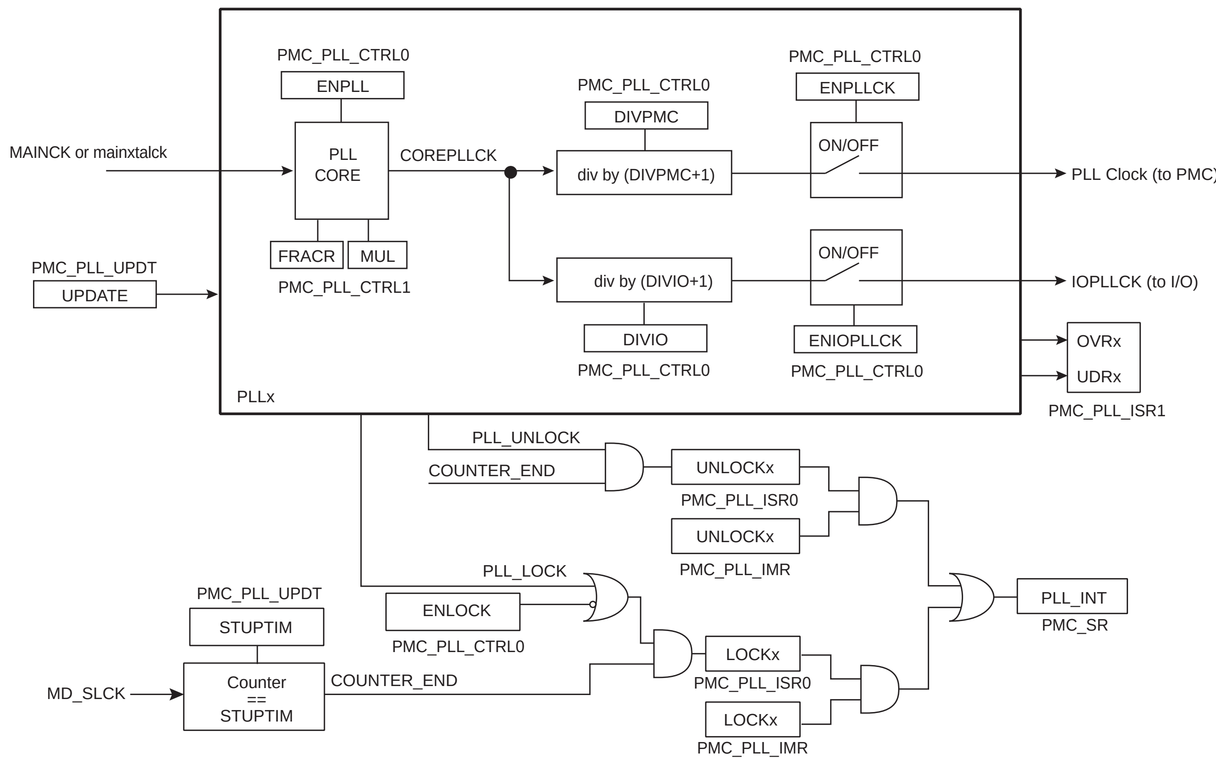
If neither the start-up time nor the lock are enabled, there is no way to know the lock status of the PLL.

The PLL also embeds an unlock status that informs when the PLL lock is lost. When enabled, this status is read once the start-up time (if defined) has elapsed.

The lock and unlock status can be used as interrupts.

See the following figure.

Figure 34-4. PLL Controls



Follow the steps below to enable a PLL:

1. Define the ID (ID=n) and start-up time by configuring the fields PMC_PLL_UPDT.ID and PMC_PLL_UPDT.STUPTIM. Set PMC_PLL_UPDT.UPDATE to ‘0’.
2. Configure PMC_PLL_ACR. See recommended values in the Electrical Characteristics section.
3. Define the MUL and FRACR to be applied to PLL(n) in PMC_PLL_CTRL1.
4. Set PMC_PLL_UPDT.UPDATE to ‘1’. PMC_PLL_UPDT.ID must equal the one written during Step 1., otherwise the update is cancelled.
5. In PMC_PLL_CTRL0, write a ‘1’ to ENLOCK and to ENPLL and configure DIVPMC, DIVIO, ENPLLCK and ENIOPLLCK.
6. Set PMC_PLL_UPDT.UPDATE to ‘1’. PMC_PLL_UPDT.ID must equal the one written during Step 1. otherwise the update is cancelled.
7. Wait for the lock bit to rise by polling the PMC_PLL_ISR0 or by enabling the corresponding interrupt in PMC_PLL_IER.
8. Disable the interrupt (if enabled).
9. Enable the unlock interrupt to quickly detect a failure on the generation of the PLL clock.

Once enabled (PMC_PLL_CTRL0.ENPLL=1), the PLL core generates its core clock (COREPLLCK).

Once the PLL has been enabled and has locked, the PLL configuration can be modified without switching off the cell.

The clock generated by the PLL is sent to the PMC if ENPLLCK is set to ‘1’ and the PMC_PLL_UPDT.UPDATE bit has then been written to ‘1’.

If the corresponding IOPLLCK is implemented, the clock generated by the PLL is sent to the IO if ENIOPLLCK was set to 1 and then PMC_PLL_UPDT.UPDATE was written to 1.

To disable a PLL, the following sequence must be applied:

1. If the PLL drives a section of the system that is active, modify the source clock of the system.
2. Define the ID (ID=n) of the PLL to be switched off in PMC_UPDT. The bit UPDATE in this register must be set at 0 in this step.
3. In PMC_PLL_CTRL0, set ENPLLCK and ENIOPLLCK to 0 and leave ENPLL at ‘1’.

4. Set PMC_PLL_UPDT.UPDATE to ‘1’. PMC_PLL_UPDT.ID must equal the one written during step 2, otherwise the update is cancelled.
5. Write a ‘0’ to PMC_PLL_CTRL0.ENPLL.
6. Set PMC_PLL_UPDT.UPDATE to ‘1’. PMC_PLL_UPDT.ID must equal the one written during Step 2., otherwise the update is cancelled.

34.6.2 UTMI PLL

UTMI PLLs are controlled in USB 2.0 PHYs. Refer to the section “USB 2.0 PHY”.

34.6.3 PLL Unlock

Each PLL has an unlock flag. It is recommended to set the UNLOCK interrupt by setting the corresponding PMC_PLL_IER.UNLOCK bit to quickly detect a failure on PLL clock generation.

The rise of a PLL unlock signal implies a failure in the normal operation of the PLL (input clock loss, for example). In this case, the PLL keeps operating but stops trying to lock the input clock. A manual clock switching to a stable clock should be performed to ensure CPU_CLK integrity

34.6.4 Spread Spectrum

Spread spectrum is obtained by slightly modifying the PLL target frequency. Two parameters are used to configure the spread spectrum:

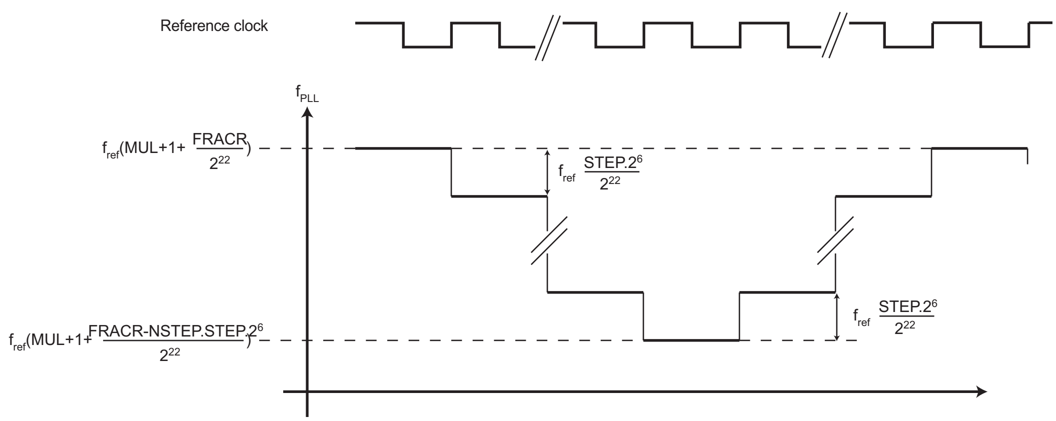
- STEP—the frequency step
- NSTEP—the number of times the STEP will be applied

The spread spectrum can be applied only if the PLL is already enabled and locked. Once the spread spectrum has been enabled, it is no longer possible to modify the target frequency of the PLL. Prior to change the PLL frequency, the spread spectrum must be disabled and a period of 2 x NSTEP cycles of the PLL source clock must elapse.

When enabled, the spread spectrum logic modifies the fractional part of the PLL. The fractional factor applied to the PLL is in the following range: FRACR - (64 x STEP x NSTEP) up to FRACR.

Starting from the base frequency of the PLL configured in PMC_PLL_CTRL1 (MUL, FRACR), the spread spectrum mechanism decreases the PLL frequency, and when the minimum is reached, the PLL frequency is increased up to the value configured through the PMC_PLL_CTRL1 register (the PLL frequency never overpasses that value).

Figure 34-5. Spread Spectrum Mechanism



35. Power Management Controller (PMC)

35.1 Description

The Power Management Controller (PMC) optimizes power consumption by controlling all system and user peripheral clocks. The PMC enables/disables the clock inputs to many of the peripherals and to the processor.

The Slow Clock Controller (SCKC) selects the source of TD_SLCK (drives the real-time part (RTT/RTC)). The source of MD_SLCK (drives the rest of the system controller: wake-up logic, watchdog, PMC, etc.) is always the slow RC oscillator.

For the out of ROM configuration, refer to the section “Boot Strategies”.

35.2 Embedded Characteristics

The Power Management Controller provides the following clocks:

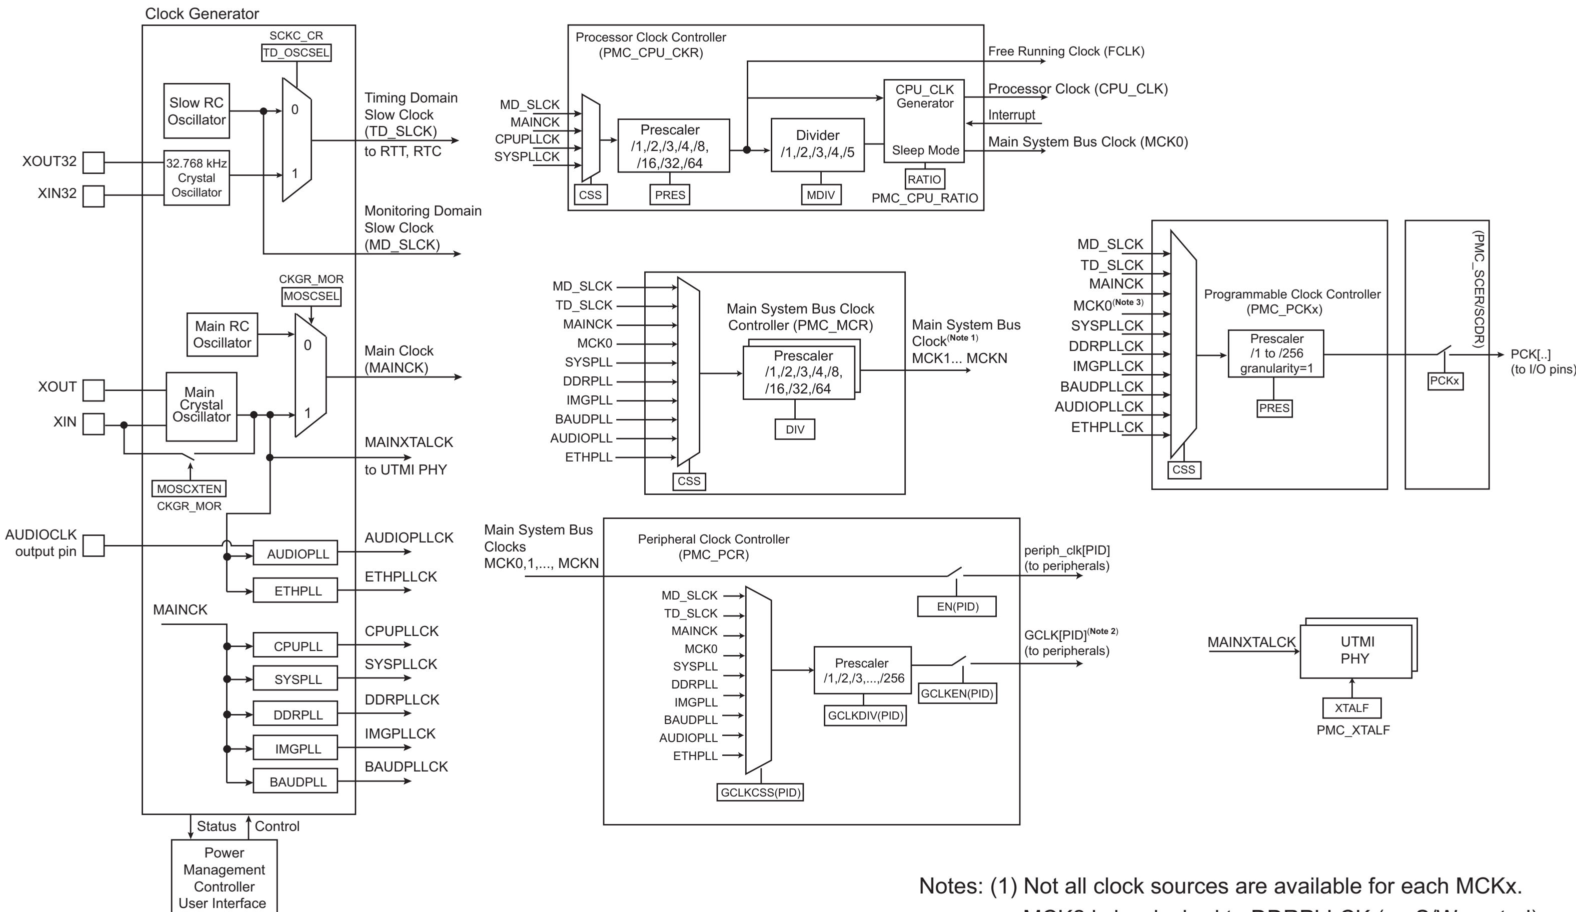
- Main System Bus Clocks (MCKx)—clock signals that are the root clock of a group of peripherals. They are programmable from a few hundred Hz to the maximum operating frequency of the peripheral group. MCK0 is the main system bus clock associated to all peripherals that are synchronous with the processor.
- Processor Clock (CPU_CLK)—can be tuned through a frequency scaler module and automatically switched off when entering the processor in Sleep mode.
- Free-running Processor Clock (FCLK)—the source clock of CPU_CLK. Is not affected when Sleep mode or the frequency scaler is activated.
- Peripheral Clocks with independent on/off control, provided to the peripherals. Each peripheral clock is inherited from one of the MCKx clocks.
- Programmable Clock Outputs (PCKx), selected from the clock generator outputs to drive the device PCKx pins.
- Generic Clock (GCLK) with controllable division and on/off control, independent of MCKx and CPU_CLK. Provided to selected peripherals. Refer to the table “Peripheral Identifiers” for more details on GCLK availability per peripheral.

The Power Management Controller also provides the following features on clocks:

- A main crystal oscillator failure detector
- A 32.768 kHz crystal oscillator frequency monitor
- A frequency counter on main crystal oscillator or main RC oscillator
- An MCK0 failure detector

35.3 Block Diagram

Figure 35-1. General Clock Distribution Block Diagram



Notes: (1) Not all clock sources are available for each MCKx.
MCK2 is hard-wired to DDRPLLCK (no S/W control).
(2) Not all clock sources are available for each GCLK[PID].
(3) As MCK0=CPU_CLK/PMC_CPU_CKR.MDIV,
MCK0 is not independent from CPU_CLK. Take this into account in case of CPU frequency scaling.

35.4 Processor Clock Controller

The PMC features a Processor Clock (CPU_CLK) controller that implements the processor Sleep mode. CPU_CLK can be disabled by executing the WFI (WaitForInterrupt) or the WFE (WaitForEvent) processor instruction.

CPU_CLK is enabled after a reset and is automatically re-enabled by any enabled interrupt. The processor Sleep mode is entered by disabling CPU_CLK, which is automatically re-enabled by any enabled interrupt, or by the reset of the product.

When processor Sleep mode is entered, the current instruction is finished before the CPU_CLK is stopped, but this does not prevent data transfers from other hosts of the system bus.

The clock selection is done in PMC_CPU_CKR.CSS.

The prescaler is configured in PMC_CPU_CKR.PRES.

The Processor Clock Controller also generates a main system bus clock, MCK0, which is a subdivision of the FCLK.

Only one of CSS, PRES and MDIV fields can be modified at a time. When one of these parameters is modified, no other modification can be performed on these fields as long as the MCKRDY status flag is low.

Any modification in CSS, PRES or MDIV fields must never lead to generate an MCK frequency that is greater than the maximum allowed system frequency. When changing the source clock of the system to a faster clock, the fields must be modified using the following order: MDIV, PRES and then CSS. When changing the source clock of the system to a slower clock, the fields must be modified using the following order: CSS, PRES and then MDIV.

If the destination clock does not exist, the switching is not performed. The CPU_CLK keeps running with the previous clock and the system must be reset to run correctly again.

The user must implement a timeout when monitoring the MCKRDY flag after a clock source switching in order to perform a reset in case switching fails.

The Processor Clock Controller features a dynamic frequency scaling mechanism that allows the CPU_CLK to be a non-integer division of the free-running clock.

35.4.1 Processor Clock Ratio

The Processor Clock frequency can be controlled more precisely with the PMC_CPU_RATIO.RATIO.

$$f_{\mathrm{CPU}} = \frac{(\mathrm{RATIO} + 1)}{16} \times f_{\mathrm{FCLK}}$$

By default, RATIO = 15, and the Processor Clock frequency equals the Free-running Clock frequency. Modifying the RATIO field modifies the frequency of the Processor Clock with a frequency step of $f_{FCLK}/16$.

35.5 Free-running Processor Clock

The free-running Processor clock (FCLK) used for sampling interrupts and clocking debug blocks ensures that interrupts can be sampled, and sleep events can be traced, while the processor is sleeping.

35.6 Main System Bus Clock Controller

The Main System Bus Clock Controller provides the main system bus clocks (MCKx) of the different peripheral groups, with the exception of MCK0 that is generated by the Processor Clock Controller and MCK2 that is hard-wired to DDRPLLCK. MCKx are the source clocks of the peripheral clocks. Each peripheral clock is generated by one MCKx. To know which peripherals are clocked by a specific MCKx, refer to the Peripheral Identifiers table in the section "System Interconnect and Security (SIS)".

When configuring an MCKx, it is mandatory to write PMC_MCR.CMD to ‘1’ and PMC_MCR.ID with the index of the corresponding MCKx.

To read the current configuration of an MCKx, PMC_MCR must be first accessed with PMC_MCR.CMD written to ‘0’ and PMC_MCR.PID field written with the index of the corresponding MCKx. This write does not modify the configuration of the peripheral. The PMC_MCR can then be read to know the configuration status of the corresponding PID.

The clock selection is done in PMC_MCR.CSS.

The prescaler is configured in PMC_MCR.PRES.

Each time PMC_MCR.CSS is configured to define a new MCKx, PMC_SR.MCKXRDY is cleared. It reads ‘0’ until all MCKx are established. Then, MCKXRDY is set and can trigger an interrupt to the processor.

Table 35-1. Available Input for Each MCKx

Clock Sources	Main System Bus Clocks				
	MCK0	MCK1	MCK2	MCK3	MCK4
MD_SLCK	X	X	–	X	X
MAINCK	X	X	–	X	X
MCK0	–	X	–	X	X
SYSPLLCK	X	X	–	X	X

...........continued

Clock Sources	Main System Bus Clocks				
	MCK0	MCK1	MCK2	MCK3	MCK4
ETHPLLCK	–	–	–	–	–
IMGPLLCK	–	–	–	X	–
DDRPLLCK	–	–	X	X	–
CPUPLLCK	X	–	–	–	–

35.7 Peripheral and Generic Clock Controller

The PMC controls the clocks of the embedded peripherals by means of the Peripheral Control register (PMC_PCR). With this register, the user can enable and disable the different clocks used by the peripherals:

- Peripheral clocks (periph_clk[PID]), routed to every peripheral and derived from the corresponding MCKx. It is mandatory to enable this clock before using a peripheral.
- Generic clocks (GCLK[PID]), routed to selected peripherals only (refer to the “Peripheral Identifiers” table). These clocks are independent of the core and bus clocks (CPU_CLK, MCKx and periph_clk[PID]). They are generated by selection and division of available sources. The list of available source clocks depends on the peripheral. Refer to the description of each peripheral to know available sources and limitations to be applied to GCLK[PID] compared to periph_clk[PID].

To configure a peripheral’s clocks, PMC_PCR.CMD must be written to ‘1’ and PMC_PCR.PID must be written with the index of the corresponding peripheral. All other configuration fields must be correctly set.

To read the current clock configuration of a peripheral, PMC_PCR must be first accessed with PMC_PCR.CMD bit written to ‘0’ and PMC_PCR.PID field written with the index of the corresponding peripheral. This write does not modify the configuration of the peripheral. The PMC_PCR can then be read to know the configuration status of the corresponding PID.

The status of the peripheral clock activity can be read in the Peripheral Clock Status registers (PMC_CSRx).

The status of the peripheral generic clock activity can be read in the Generic Clock Status registers (PMC_GCSRx).

When a peripheral or a generic clock is disabled, it is immediately stopped. These clocks are disabled after a reset. The source and the division ratio of generic clocks must not be modified while the peripheral is enabled. The generic clock configuration must be set before the peripheral is enabled.

To stop a peripheral clock, it is recommended that the system software wait until the peripheral has executed its last programmed operation before disabling the clock. This is to avoid data corruption or erroneous behavior of the system.

35.8 Programmable Clock Output Controller

The PMC controls six signals to be output on the external pins PCKx. Each signal can be independently programmed via the Programmable Clock registers (PMC_PCKx).

PCKx can be independently selected between MD_SLCK, TD_SLCK, MAINCK, MCK0 and any PLLCK except PLLCK[0] by configuring PMC_PCKx.CSS. Each output signal can also be divided by 1 to 256 by configuring PMC_PCKx.PRES.

Each output signal can be enabled and disabled by writing a ‘1’ to the corresponding bits PMC_SCER.PCKx and PMC_SCDR.PCKx, respectively. The status of the active programmable output clocks is given in PMC_SCSR.PCKx.

The status flag PMC_SR.PCKRDYx indicates that the clock configured through the PMC_PCKx register is correctly established.

As the Programmable Clock Controller does not manage with glitch prevention when switching clocks, it is strongly recommended to disable PCKx before any configuration change and to re-enable it once the change is performed.

35.9 Ultra-Low Power Modes and Fast Start-Up

35.9.1 ULP1 and ULP2 Modes

Refer to the section “Electrical Characteristics”.

35.9.2 Fast Start-Up

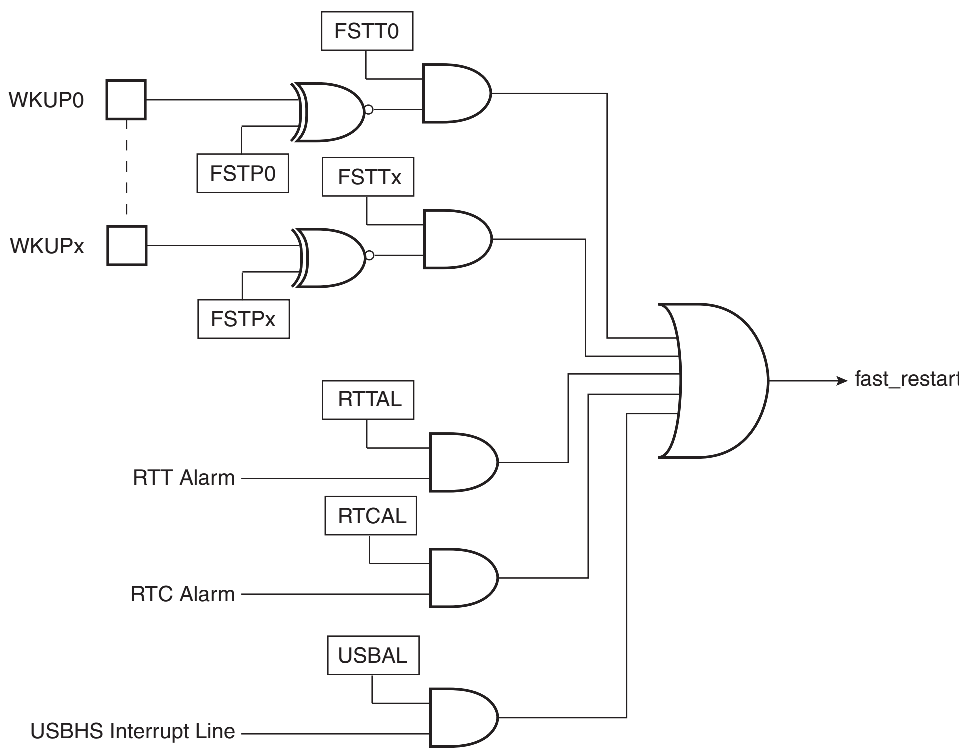
At exit from ULP1 or ULP2 mode, the device allows the processor to restart in several microseconds only if the C-code function that manages the ULP1 or ULP2 mode entry and exit is linked to and executed from on-chip SRAM.

A fast start-up occurs upon the detection of a programmed level on one of the wake-up inputs (WKUP) or upon an active alarm from the RTC, RTT and USB Controller. The polarity of each of the wake-up inputs is programmable in the PMC Wake-Up Control Register (PMC_WCR).

⚠WARNING The duration of the WKUPx pins active level must be greater than four MAINCK cycles.

The fast start-up circuitry, as shown in the following figure, is fully asynchronous and provides a fast start-up signal to the PMC. As soon as the fast start-up signal is asserted, the main RC oscillator restarts automatically.

Figure 35-2. Fast Start-Up Circuitry



Each wake-up input pin can be configured to generate a fast start-up event by setting the corresponding bits in PMC_WCR.

To configure a wake-up pin, a write access must be performed in PMC_WCR (CMD=’1’). Field PID must be written with the ID of the wake-up pin, FSTP set to the polarity of the wake-up pin and EN set to enable/disable the wake-up pin.

To read the configuration status of a wake-up pin, PMC_WCR.PID must be written with the ID of the wake-up pin and the CMD bit set to ‘0’. Then the next read access to PMC_WCR sends the configuration status of the wake-up pin specified in PID.

Each alarm can be enabled to generate a fast start-up event by setting the corresponding bit in PMC_FSMR.

The user interface does not provide any status for fast start-up. The status can be read in the PIO Controller and the status registers of the RTC, RTT and USB Controller.

35.10 Asynchronous Partial Wake-Up

35.10.1 Description

The asynchronous partial wake-up wakes up a peripheral in a fully asynchronous way when activity is detected on the communication line. The asynchronous partial wake-up function automatically manages the peripheral clock. It reduces overall power consumption of the system by clocking peripherals only when needed.

Asynchronous partial wake-up can be enabled in ULP1, ULP2 or Active mode.

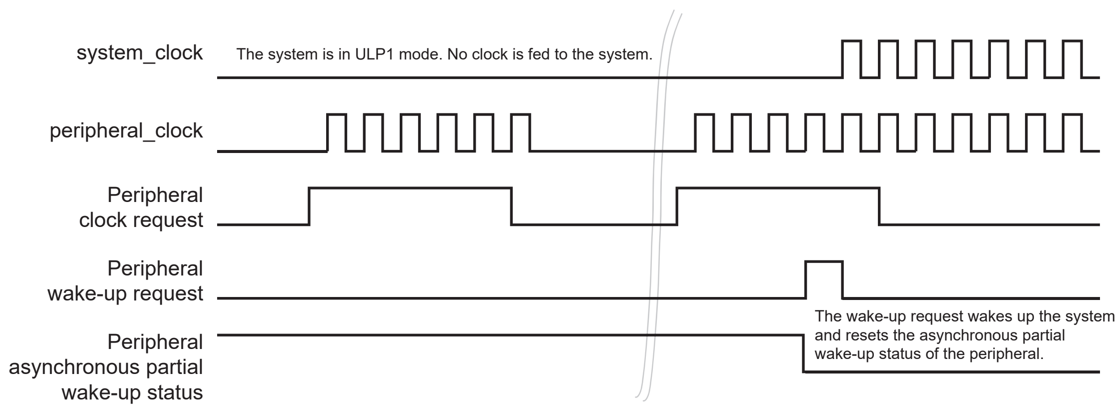
Only the following peripherals can be configured with asynchronous partial wake-up: FLEXCOMx and ADCC.

The peripheral selected for asynchronous partial wake-up must first be configured so that its clock is enabled. To do so, configure PMC_PCR.PID and write a ‘1 to PMC_PCR.EN.

35.10.2 Asynchronous Partial Wake-Up when System is in ULP1 Mode

When an asynchronous clock request from a peripheral occurs, the PMC partially wakes up the system to feed the clock only to this peripheral. The rest of the system is not fed with the clock, thus optimizing power consumption. Finally, depending on user-configurable conditions, the peripheral either wakes up the whole system if these conditions are met or stops the peripheral clock until the next clock request. If a wake-up request occurs, asynchronous partial wake-up is automatically disabled until the user instructs the PMC to enable it. This is done by writing a ‘1’ to SLPWKSR in the Asynchronous Partial Wake-Up Control register (PMC_SLPWKCR).

Figure 35-3. System Asynchronous Partial Wake-Up Waveforms



35.10.2.1 Configuration Procedure

Before configuring asynchronous partial wake-up for a peripheral, check that the PIDx bit in PMC_CSR is set. This ensures that the peripheral clock is enabled.

The steps to enable asynchronous partial wake-up for a peripheral are the following:

1. Check that PMC_SLPWKCR.ASR is set to ‘0’ for the corresponding peripheral. This ensures that the peripheral has no activity in progress.
2. Enable asynchronous partial wake-up for the peripheral by writing a ‘1’ to PMC_SLPWKCR.SLPWKSR.
3. Check that PMC_SLPWKCR.ASR is set to '0'. This ensures that no activity has started during the enable phase.
   If PMC_SLPWKCR.ASR=1, proceed to the next step.

   If PMC_SLPWKCR.ASR=0, Asynchronous Partial Wake-up mode is active for the peripheral. Before entering ULP1 or ULP2 mode, check that the AIP bit in the Asynchronous Partial Wake-Up Activity In Progress register (PMC_SLPWK_AIPR) is cleared. This ensures that the peripheral has no activity in progress due to a reactivation.
4. In PMC_SLPWKCR, asynchronous partial wake-up must be immediately disabled by writing a ‘0’ to SLPWKSR. Wait for the end of peripheral activity before reinitializing the procedure.

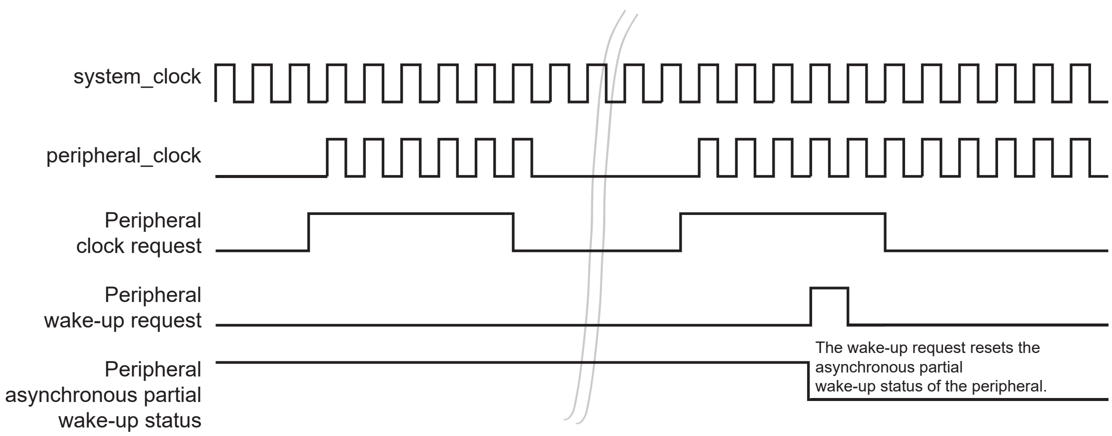
35.10.3 Asynchronous Partial Wake-Up of a Peripheral in Active Mode

When the system is in Active mode, peripherals enabled for asynchronous partial wake-up have their respective clocks stopped until the peripherals request a clock. When a peripheral requests the clock, the PMC provides the clock without processor intervention.

The triggering of the peripheral clock request depends on conditions which can be configured for each peripheral. If these conditions are met, the peripheral asserts a request to the PMC. The PMC disables the Asynchronous Partial Wake-up mode of the peripheral and provides the clock to the peripheral until the user instructs the PMC to re-enable partial wake-up on the peripheral. This is done by setting PMC_SLPWKCR.SLPWKSR.

If the conditions are not met, the peripheral clears the clock request and the PMC stops the peripheral clock until the clock request is reasserted by the peripheral.

Figure 35-4. Asynchronous Partial Wake-up in Active Mode



35.10.3.1 Configuration Procedure

Before configuring the asynchronous partial wake-up function of a peripheral, check that the PIDx bit in PMC_CSR is set. This ensures that the peripheral clock is enabled.

The steps to enable the asynchronous partial wake-up function of a peripheral are the following:

1. Check that PMC_SLPWKCR.ASR is set to ‘0’. This ensures that the peripheral has no activity in progress.
2. Enable the asynchronous partial wake-up function of the peripheral by writing a ‘1’ to PMC_SLPWK_ER.SLPWKSR.
3. Check that PMC_SLPWKCR.ASR is set to '0'. This ensures that no activity has started during the enable phase.
   If PMC_SLPWKCR.ASR=1, proceed to the next step.

   If PMC_SLPWKCR.ASR=0, Asynchronous Partial Wake-up mode is active for the peripheral. Before entering ULP1 or ULP2 mode, check that the AIP bit in the PMC Asynchronous Partial Wake-Up Activity In Progress register (PMC_SLPWK_AIPR) is cleared. This ensures that the peripheral has no activity in progress due to a reactivation.
4. In PMC_SLPWKCR, asynchronous partial wake-up must be immediately disabled by writing a ‘0’ to SLPWKSR. Wait for the end of peripheral activity before reinitializing the procedure.

Note: If an activity has started during the enable phase, the asynchronous partial wake-up function must be immediately disabled by writing a ‘0’ to PMC_SLPWKCR.SLPWKSR. Wait for the end of peripheral activity before reinitializing the procedure.When asynchronous partial wake-up for a peripheral is enabled and the core is running (system not in ULP1 or ULP2 mode), the peripheral must not be accessed before a wake-up of the peripheral is performed.

35.11 Main Crystal Oscillator Failure Detection

The main crystal oscillator failure detector monitors the main crystal oscillator against the slow RC oscillator and provides an automatic switchover of the MAINCK source to the main RC oscillator in case of failure detection.

The failure detector can be enabled or disabled by configuring CKGR_MOR.CFDEN. It cannot be enabled if the main crystal oscillator is disabled. It must be disabled before disabling the main crystal oscillator.

It is also disabled in either of the following cases:

- after a VDDCORE reset
- when the main crystal oscillator is disabled (MOSCXTEN = 0)

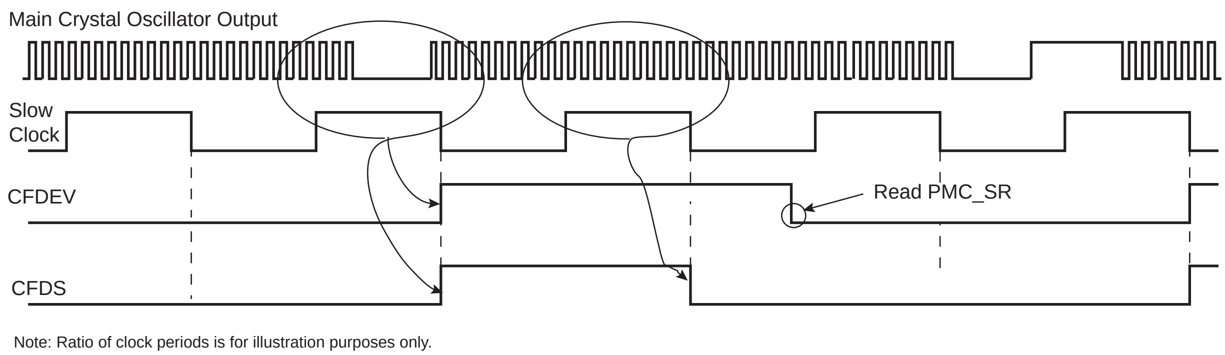
A failure is detected by means of a counter incrementing on the main crystal oscillator output and detection logic is triggered by the slow RC oscillator which is automatically enabled when CFDEN = 1.

The counter is cleared when the slow RC oscillator clock signal is low and enabled when the signal is high. Thus, the failure detection time is one slow RC oscillator period. If, during the high level period of the slow RC oscillator clock signal, less than eight main crystal oscillator clock periods have been counted, then a failure is reported. Note that when enabling the failure detector, up to two cycles of the slow RC oscillator are needed to detect a failure of the main crystal oscillator.

If a main crystal oscillator failure is detected, PMC_SR.CFDEV and PMC_SR.FOS both indicate a failure event. PMC_SR.CFDEV is cleared on read of PMC_SR, and PMC_SR.FOS is cleared by writing a ‘1’ to the FOCLR bit in the PMC Fault Output Clear register (PMC_FOCR).

Only PMC_SR.CFDEV can generate an interrupt if the corresponding interrupt source is enabled in PMC_IER. The current status of the clock failure detection can be read at any time from PMC_SR.CFDS.

Figure 35-5. Clock Failure Detection Example



If the CKGR_MOR.AUTOMAINSW bit is set to'1', the source of MAINCK automatically switches to the MAIN RC oscillator. If the main RC oscillator was previously powered off, it is first powered on before switching. If the CKGR_MOR.AUTOCPUSW bit is set to'1', the source of MCK0 automatically switches to MAINCK.

If the main crystal oscillator is selected as the source of MAINCK, the PMC can be configured to automatically select the main RC oscillator as the source of MAINCK in case of a main crystal oscillator failure detection by setting the CKGR_MOR.AUTOMAINSW to '1'. Additionally, if the source of CPU_CLK is a PLL driven by the main crystal oscillator, the PMC can be configured to automatically select the MAINCK as the source of CPU_CLK in case of a main crystal oscillator failure detection by setting the CKGR_MOR.AUTOCPUSW to '1'. CKGR_MOR.AUTOMAINSW must be set to '1' prior to setting CKGR_MOR.AUTOCPUSW to '1'.

Two slow RC oscillator clock cycles are necessary to detect and switch from the main crystal oscillator to the main RC oscillator if the source of MCK0 is MAINCK, or three slow RC oscillator clock cycles if the source of MCK0 is a PLL.

A clock failure detection activates a fault output that is connected to the Pulse Width Modulator (PWM) controller. With this connection, the PWM controller is able to force its outputs and to protect the driven device if a clock failure is detected.

35.12 32.768 kHz Crystal Oscillator Frequency Monitor

The frequency of the 32.768 kHz crystal oscillator can be monitored by configuring CKGR_MOR.XT32KFME. Prior to enabling the monitoring, the 32.768 kHz crystal oscillator must be started and its start-up time be elapsed. Refer to the section “Slow Clock Controller (SCKC)” for details on the slow clock generator.

An error flag (PMC_SR.XT32KERR) is asserted when the 32.768 kHz crystal oscillator frequency is out of its nominal frequency value (i.e., 32.768 kHz). The error flag can be cleared only if the monitoring is disabled.

The frequency drift is computed with the main RC oscillator.

The monitored clock frequency is declared invalid if at least four consecutive 32.768 kHz crystal oscillator clock period measurement results are over the nominal period.

The error flag can be defined as an interrupt source of the PMC by setting PMC_IER.XT32KERR. This flag is also routed to the Reset Controller (RSTC) and may generate a reset of the device.

35.13 MCK0 Frequency Monitor

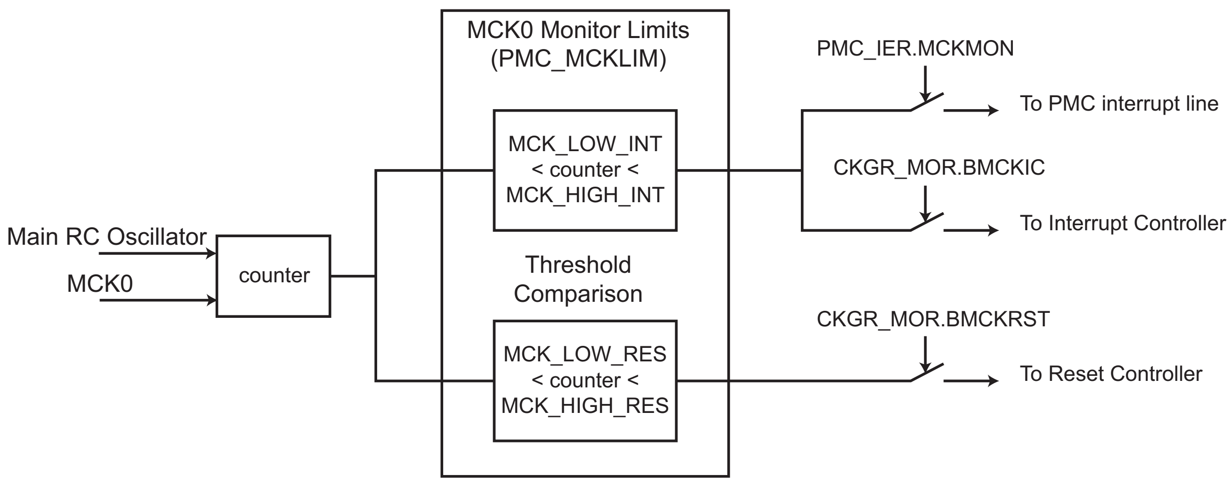
The frequency of MCK0 can be monitored with the main RC oscillator. This monitoring can only be performed if the MCK0 frequency is at least three times faster than the embedded main RC oscillator. This function is enabled by writing a ‘1’ to CKGR_MOR.BMCKIC, CKGR_MOR.BMCKRST or PMC_IER.MCKMON.

An error on the MCK0 frequency can lead to a PMC interrupt or a reset of the system (refer to the section “Reset Controller (RSTC)”).

When the corresponding PMC interrupt is enabled, the status of the MCK0 monitoring can be read on PMC_SR.MCKMON. This status is cleared on read.

Once enabled, the monitor continuously counts the number of MCK0 cycles within 15 cycles of the embedded main RC oscillator. The result is then compared to threshold values defined in the PMC_MCKLIM register. Two levels of thresholds can be defined: a first couple of values defines thresholds to generate an interrupt and a second couple of values defines thresholds to generate a reset of the system.

Figure 35-6. MCK0 Frequency Monitor



35.14 Recommended Programming Sequence

Follow the steps below to program the PMC:

1. If the main crystal oscillator is not required, the PLL can be directly configured (step 5) else this oscillator must be started (step 2).
2. Verify the existence and frequency value of the main crystal oscillator following the sequence defined in Main Frequency Counter
3. If the main crystal oscillator is enabled and valid, the source of MAINCK can be switched to the main crystal oscillator by writing CKGR_MOR.MOSCSEL to 1 else the PLL can be directly configured.
4. Wait for the end of the MAINCK source switching by either polling the MOSCSELS or setting the corresponding interrupt
5. Configure the PLLs by following the setup defined in Divider and Phase Lock Loop Programming (if not required, proceed to step 6):

6. Configure the MCK0 division ratio by setting PMC_CPU_CKR.MDIV. Available values are 0, 1, 2, 3, 4. MCK0 output is the CPU_CLK frequency divided by 1, 2, 3, 4 or 5, depending on the value programmed in MDIV. By default, MDIV is cleared, which indicates that the CPU_CLK is equal to MCK0.
7. Wait for the end of the MCK0 ratio switching by either polling the MCKRDY or setting the corresponding interrupt.
8. Select the division ratio of CPU_CLK by setting PMC_CPU_CKR.PRES.
   PRES is used to define the CPU_CLK and MCK0 prescaler. The user can choose between different values (1, 2, 3, 4, 8, 16, 32, 64). Prescaler output is the selected clock source frequency divided by the PRES value.
9. Wait for the end of the CPU_CLK ratio switching by either polling the MCKRDY or setting the corresponding interrupt.
10. Select the source clock of CPU_CLK by setting PMC_CPU_CKR.CSS.
    CSS is used to select the clock source of MCK0 and CPU_CLK. By default, the selected clock source is MAINCK.
11. Wait for the end of the CPU_CLK source switching by either polling the MCKRDY or setting the corresponding interrupt.
    PMC_CPU_CKR must not be programmed in a single write operation.

    Reconfiguring MDIV, PRES and CSS fields must always be done by following the right order of operation described above (steps 6 to 11).
12. Configure the prescaler of MCKx in PMC_MCR.PRES.
13. Configure the source of MCKx in PMC_MCR.CSS.
14. Configure the programmable clocks (PCKx):
    PCKx are controlled via registers PMC_SCER, PMC_SCDR and PMC_SCSR.

    PCKx can be enabled and/or disabled via PMC_SCER and PMC_SCDR. Three PCKx can be used. PMC_SCSR indicates which PCKx is enabled. By default all PCKx are disabled.

    PMC_PCKx registers are used to configure PCKx as described in Programmable Clock Output Controller.
15. Enable the peripheral and generic clocks.
    Once all of the previous steps have been completed, the peripheral and generic clocks can be configured via register PMC_PCR as described in Peripheral and Generic Clock Controller.

Note: As MCK0=CPU_CLK/PMC_CPU_CKR.MDIV, MCK0 is not independent from CPU_CLK. Take this into account in case of CPU frequency scaling.

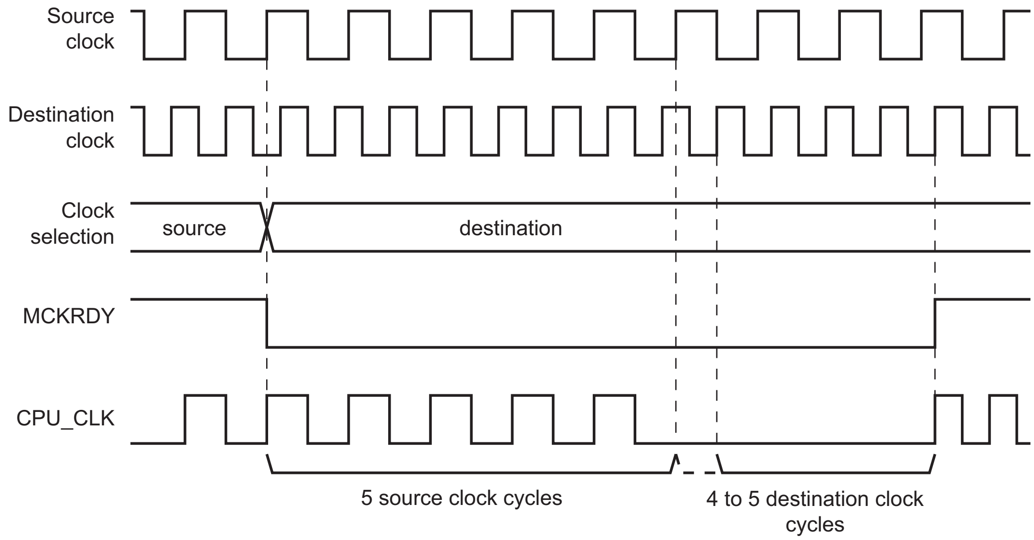
35.15 Clock Switching Details

35.15.1 CPU Clock Switching Timings

The glitch-free clock switcher implemented to control the sources of CPU_CLK and MCK0 performs clock switching in 5 clock cycles of the currently used clock plus 5 cycles of the target clock.

The clock switching is effective once MCKRDY rises. See the following figure.

Figure 35-7. Switch CPU Clock (CPU_CLK) from Source Clock to Destination Clock

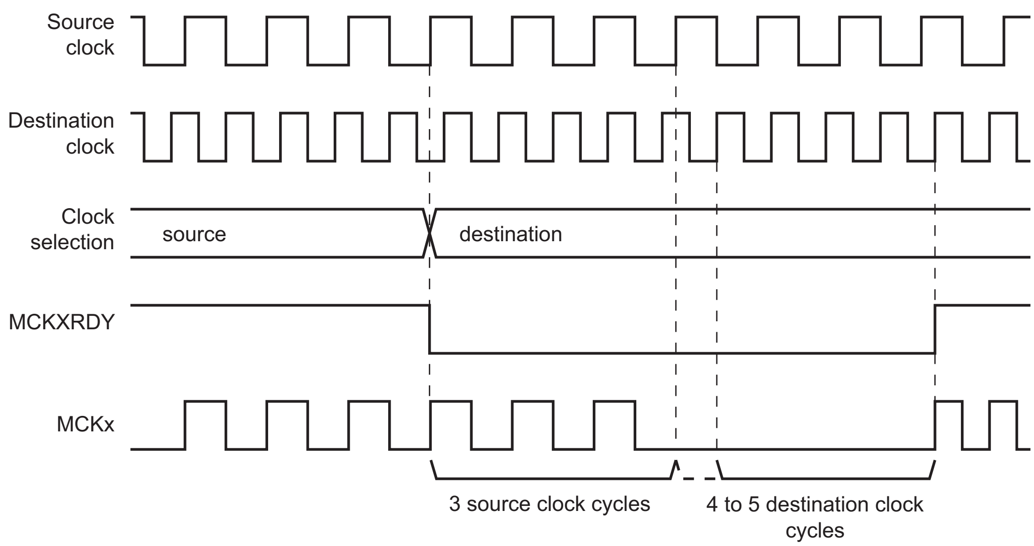


35.15.2 Main System Bus Clocks Switching Timings

The glitch-free clock switcher implemented to control the sources of MCKx (except MCK0) performs the clock switching in 3 clock cycles of the currently used clock plus 3 cycles of the target clock.

The clock switching is effective once MCKXRDY rises. See the following figure.

Figure 35-8. Switch Domain Clock (MCKx) from Source Clock to Destination Clock



35.16 Register Write Protection

To prevent any single software error from corrupting PMC behavior, certain registers in the address space can be write-protected by setting the WPEN bit or the WPITEN bit in the PMC Write Protection Mode Register (PMC_WPMR).

If a write access to a write-protected register is detected, the WPVS flag in the PMC Write Protection Status Register (PMC_WPSR) is set and the field WPVSRC indicates the register in which the write access has been attempted.

The WPVS bit is automatically cleared after reading the PMC_WPSR.

The following registers are write-protected when the WPEN bit is set in PMC_WPMR:

- PMC System Clock Enable Register
- PMC System Clock Disable Register
- PMC PLL Control Register 0
- PMC PLL Control Register 1
- PMC PLL Spread Spectrum Register
- PMC PLL Analog Control Register
- PMC PLL Update Register
- PMC Clock Generator Main Oscillator Register
- PMC Clock Generator Main Clock Frequency Register
- PMC CPU Clock Register
- PMC CPU Clock Ratio Register
- PMC Main System Bus Clock Register
- PMC Programmable Clock Register
- PMC Fast Start-Up Mode Register
- PMC Wake-Up Control Register
- PMC Peripheral Control Register
- PMC Asynchronous Partial Wake-Up Control Register
- PMC MCK0 Monitor Limits Register

The following interrupt registers are write-protected when the WPITEN bit is set in PMC_WPMR:

- PMC Interrupt Enable Register
- PMC Interrupt Disable Register
- PMC PLL Interrupt Enable Register
- PMC PLL Interrupt Disable Register

35.17 Register Summary

Bits 8, 9, 10, 11, 12, 13, 14, 15 – PCKx Programmable Clock x Output Status

Value	Description
0	The corresponding Programmable Clock output is disabled.
1	The corresponding Programmable Clock output is enabled.

35.17.4 PMC PLL Control Register 0

Name: PMC_PLL_CTRL0
Offset: 0x000C
Reset: 0x00000000
Property: Read/Write

All fields defined here are applied to the PLL defined by the last ID field written in the PMC_PLL_UPDT register.

Bit	31	30	29	28	27	26	25	24
	ENLOCK	ENIOPLLCK	ENPLLCK	ENPLL				
Access	R/W	R/W	R/W	R/W

	DIVPMC[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit 31 – ENLOCK Enable PLL Lock

Value	Description
0	The lock signal sent by the PLL is ignored. The PLL is considered as locked once the start-up time defined by PMC_PLL_UPDT.STUPTIM has elapsed.
1	The PLL is considered as locked once the start-up time defined by PMC_PLL_UPDT.STUPTIM has elapsed and the lock signal sent by the PLL has risen.

Bit 30 – ENIOPLLCK Enable PLL Clock for IO
This feature is available for AUDIOPLL only. If the DIVIO field is equal to 0, this bit can be used to enable or disable the PLL clock on the IO. If DIVIO is not equal to 0, the PLL clock on the IO is always active.

Value	Description
0	The clock generated by the PLL is not sent to the IO.
1	The clock generated by the PLL is sent to the IO.

Bit 29 – ENPLLCK Enable PLL Clock for PMC
This feature is available for all PLLs. If the DIVPMC field is equal to 0, this bit can be used to enable or disable the PLL clock to the PMC. If DIVPMC is not equal to 0, the PLL clock to the PMC is always active.

Value	Description
0	The clock generated by the PLL is not send to the PMC.
1	The clock generated by the PLL is sent to the PMC.

Bit 28 – ENPLL Enable PLL

Value	Description
0	The PLL is off.
1	The PLL is on.

Bits 19:12 – DIVIO[7:0] Divider for PAD
Specifies the division ratio applied to the internal PLL clock before being sent to the IO. This feature is not available for all PLLs. Refer to PLL characteristics in the section “Electrical Characteristics” for more information. This feature is only available for AUDIOPLL. The frequency is defined by the following formula:

$$f_{\mathrm{IOPLLCK}} = \frac{f_{\mathrm{COREPLLCK}}}{(\mathrm{DIVIO} + 1)}$$

Bits 7:0 – DIVPMC[7:0] Divider for PMC
Specifies the division ratio applied to the internal PLL clock before being sent to the PMC. The frequency is defined by the following formula:

$$f_{\mathrm{PLL\ Clock}} = \frac{f_{\mathrm{COREPLLCK}}}{(\mathrm{DIVPMC} + 1)}$$

35.17.5 PMC PLL Control Register 1

Name: PMC_PLL_CTRL1
Offset: 0x0010
Reset: 0x00000000
Property: Read/Write

All fields defined here are applied to the PLL defined by the last ID field written in the PMC_PLL_UPDT register.

Bit	31	30	29	28	27	26	25	24
	MUL[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Reset	0	0	0	0	0	0	0	0

Bits 31:24 – MUL[7:0] Multiplier Factor Value
Configures the internal clock frequency. See Divider and Phase Lock Loop Programming.

Bits 21:0 – FRACR[21:0] Fractional Loop Divider Setting

35.17.6 PMC PLL Spread Spectrum Register

Name: PMC_PLL_SSR
Offset: 0x0014
Reset: 0x00000000
Property: Read/Write

All fields defined here are applied to the PLL defined by the last ID field written in the PMC_PLL_UPDT register.

Bit	31	30	29	28	27	26	25	24
				ENSPREAD				
Access				R/W				
Reset				0				

Bit	23	22	21	20	19	18	17	16

	STEP[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit 28 – ENSPREAD Spread Spectrum Enable

Value	Description
0	The spread spectrum is not applied to the PLL.
1	The spread spectrum is applied to the PLL.

Bits 23:16 – NSTEP[7:0] Spread Spectrum Number of Steps
Specifies how many times STEP is applied to the PLL ratio. The value of NSTEP must be equal to or greater than 1.

Bits 15:0 – STEP[15:0] Spread Spectrum Step Size
When the spread spectrum is active, this field defines the step size that will be applied the PMC_PLL_CTRL1.FRACR factor. The step is applied on the LSB of PMC_PLL_CTRL1.FRACR.

35.17.7 PMC PLL Analog Control Register

Name: PMC_PLL_ACR
Offset: 0x0018
Reset: 0x00000030
Property: Read/Write

This register must be loaded with the recommended values described in the Electrical Characteristics section.

All fields defined here are applied to the PLL defined by the last ID field written in the PMC_PLL_UPDT register.

Bit	31	30	29	28	27	26	25	24
			LOOP_FILTER[5:0]					
Access			R/W	R/W	R/W	R/W	R/W	R/W

Bits 18:16 – LOCK_THR[2:0] PLL Lock Threshold Value Selection

Bits 11:0 – CONTROL[11:0] PLL CONTROL Value Selection

35.17.8 PMC PLL Update Register

Name: PMC_PLL_UPDT
Offset: 0x001C
Reset: 0x00030000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
			STUPTIM[5:0]					
Access			R/W	R/W	R/W	R/W	R/W	R/W
Reset			0	0	0	0	1	1

Bit	15	14	13	12	11	10	9	8
								UPDATE
Access								R/W
Reset								0

Bit	7	6	5	4	3	2	1	0
					ID[3:0]			
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bits 21:16 – STUPTIM[5:0] Start-up Time
The start-up time is defined as a number of MD_SLCK cycles and is the same for all PLLs.
STUPTIM can be modified only if all PLLs are off.

Value	Description
0	Only the lock of the PLL is considered to know the lock status of the PLL. If the lock of the PLL is not enabled, the lock never rises.
Other values	If PMC_PLL_CTRL0.ENLOCK is low, specifies the start-up time of the PLL. If PMC_PLL_CTRL0.ENLOCK is high, specifies how long the LOCK signal of the PLL is masked before being read.

Bit 8 – UPDATE PLL Setting Update (write-only)

Value	Description
0	No effect.
1	The PLL configuration written in PMC_PLL_CTRL0 and PMC_PLL_CTRL1 are applied to the PLL defined by the last ID written in the PMC_PLL_CTRL0 register.

Bits 3:0 – ID[3:0] PLL ID
When writing a PLL control register (PMC_PLL_CTRLx), this ID specifies which PLL is impacted by written fields.
When reading a PLL control register (PMC_PLL_CTRLx), this ID specifies which PLL fields are read.

Value	Name
0	PLLA
1	UTMI PLL
2	AUDIO PLL
3	LVDS PLL
4	PLLADIV2CLK

35.17.9 PMC Clock Generator Main Oscillator Register

Name: CKGR_MOR
Offset: 0x0020
Reset: 0x00000008
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the PMC Write Protection Mode Register.
Note: Bit 5 is always read at 1.

Bit	31	30	29	28	27	26	25	24
		AUTOCPUSW	AUTOMAINSW	BMCKIC	BMCKRST	XT32KFME	CFDEN	MOSCSEL
Access		R/W	R/W	R/W	R/W	R/W	R/W	R/W

	KEY[7:0]							
Access	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	MOSCXTST[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	ULP2				MOSCRCEN	ULP1		MOSCXTEN
Access	W				R/W	W		R/W
Reset	0				1	0		0

Bit 30 – AUTOCPUSW Automatic Processor Clock Source Switching

Value	Description
0	A main crystal oscillator failure detection has no effect on the processor clock source selection.
1	If a main crystal oscillator failure is detected, the processor clock source selection automatically switches to the main clock.

Bit 29 – AUTOMAINSW Automatic Main Clock Source Switching

Value	Description
0	A main crystal oscillator failure detection has no effect on the main clock source selection.
1	If a main crystal oscillator failure is detected, the main clock source selection automatically switches to the main RC.

Bit 28 – BMCKIC Bad MCK0 Clock Interrupt

Value	Description
0	An MCK0 clock failure has no effect on the Interrupt Controller.
1	An MCK0 clock failure detection sends an interrupt signal to the Interrupt Controller.

Bit 27 – BMCKRST Bad MCK0 Clock Reset Enable

Value	Description
0	An MCK0 clock failure detection cannot reset the system.
1	An MCK0 clock failure detection can reset the system if the reset controller is configured accordingly.

Bit 26 – XT32KFME 32.768 kHz Crystal Oscillator Frequency Monitoring Enable

Value	Description
0	The 32.768 kHz crystal oscillator frequency monitoring is disabled.
1	The 32.768 kHz crystal oscillator frequency monitoring is enabled.

Bit 25 – CFDEN Clock Failure Detector Enable

Value	Description
0	The clock failure detector is disabled.
1	The clock failure detector is enabled.

Bit 24 – MOSCSEL Main Clock Oscillator Selection

Value	Description
0	The main RC oscillator is selected.
1	The main crystal oscillator is selected.

Bits 23:16 – KEY[7:0] Write Access Password

Value	Name	Description
0x37	PASSWD	Writing any other value in this field aborts the write operation. Always reads as 0.

Bits 15:8 – MOSCXTST[7:0] Main Crystal Oscillator Start-up Time
Specifies the number of MD_SLCK cycles multiplied by 8 for the main crystal oscillator start-up time.

Bit 7 – ULP2 ULP2 Mode Command

Value	Description
0	No effect.
1	Enables the device to enter ULP2 mode. ULP2 mode is entered when the processor WFE instruction is executed.

Bit 3 – MOSCRCEN Main RC Oscillator Enable
When MOSCRCEN is set, the MOSCRCS flag is set once the main RC oscillator start-up time is achieved.

Value	Description
0	The main RC oscillator is disabled.
1	The main RC oscillator is enabled.

Bit 2 – ULP1 ULP1 Mode Command

Value	Description
0	No effect.
1	Puts the device in ULP1 mode.

Bit 0 – MOSCXTEN Main Crystal Oscillator Enable
A crystal must be connected between XIN and XOUT or a clock signal must be provided on XIN with XOUT grounded.
When MOSCXTEN is set, the MOSCXTS flag is set once the main crystal oscillator start-up time is achieved.

Value	Description
0	The main crystal oscillator is disabled.
1	The main crystal oscillator is enabled or in bypass.

35.17.10 PMC Clock Generator Main Clock Frequency Register

Name: CKGR_MCFR
Offset: 0x0024
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the PMC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
								CCSS
Access								R/W
Reset								0

Bit	23	22	21	20	19	18	17	16
				RCMEAS				MAINFRDY
Access				R/W				R/W
Reset				0				0

Bit	15	14	13	12	11	10	9	8
	MAINF[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	MAINF[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit 24 – CCSS Counter Clock Source Selection

Value	Description
0	The measured clock of the MAINF counter is the main RC oscillator.
1	The measured clock of the MAINF counter is the main crystal oscillator.

Bit 20 – RCMEAS RC Oscillator Frequency Measure (write-only)
The measurement is performed on the main frequency (i.e., not limited to the main RC oscillator only). If the source of MAINCK is the main crystal oscillator, the restart of measurement may not be required because of the stability of crystal oscillators.

Value	Description
0	No effect.
1	Restarts measuring of the frequency of MAINCK. MAINF carries the new frequency as soon as a low-to-high transition occurs on the MAINFRDY flag.

Bit 16 – MAINFRDY Main Clock Frequency Measure Ready
To ensure that a correct value is read on the MAINF field, the MAINFRDY flag must be read at ‘1’ then another read access must be performed on the register to get a stable value on the MAINF field.

Value	Description
0	MAINF value is not valid or the measured oscillator is disabled or a measure has just been started by means of RCMEAS.
1	The measured oscillator has been enabled previously and MAINF value is available.

Bits 15:0 – MAINF[15:0] Main Clock Frequency
Gives the number of cycles of the clock selected by the bit CCSS within 16 MD_SLCK periods. To calculate the frequency of the measured clock:
f_{SELCLK} = (MAINF x f_{MD_SLCK})/16
where frequency is in MHz.

35.17.11 PMC CPU Clock Register

Name: PMC_CPU_CKR
Offset: 0x0028
Reset: 0x00000001
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the PMC Write Protection Mode Register.

The CSS, PRES and MDIV fields cannot be modified simultaneously. If more than one field modification is required, proceed sequentially: modify the first field and wait for PMC_SR.MCKRDY low, then modify the second field and wait for PMC_SR.MCKRDY low, etc.

Bit	31	30	29	28	27	26	25	24
Access								
Reset

		PRES[2:0]					CSS[1:0]	
Access		R/W	R/W	R/W			R/W	R/W
Reset		0	0	0			0	1

Bits 10:8 – MDIV[2:0] MCK0 Division

Value	Name	Description
0	EQ_PCK	MCK0 is FCLK divided by 1.
1	PCK_DIV2	MCK0 is FCLK divided by 2.
2	PCK_DIV4	MCK0 is FCLK divided by 4.
3	PCK_DIV3	MCK0 is FCLK divided by 3.
4	PCK_DIV5	MCK0 is FCLK divided by 5.

Bits 6:4 – PRES[2:0] Processor Clock Prescaler

Value	Name	Description
0	CLK_1	Selected clock
1	CLK_2	Selected clock divided by 2
2	CLK_4	Selected clock divided by 4
3	CLK_8	Selected clock divided by 8
4	CLK_16	Selected clock divided by 16
5	CLK_32	Selected clock divided by 32
6	CLK_64	Selected clock divided by 64
7	CLK_3	Selected clock divided by 3

Bits 1:0 – CSS[1:0] MCK0 Source Selection

Value	Name	Description
0	SLOW_CLK	MD_SLCK is selected
1	MAIN_CLK	MAINCK is selected
2	CPUPLLCK	CPUPLLCK is selected

Value	Name	Description
3	SYSPLLCK	SYSPLLCK is selected

35.17.12 PMC CPU Clock Ratio Register

Name: PMC_CPU_RATIO
Offset: 0x002C
Reset: 0x0000000F
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the PMC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16

Bit 28 – EN Main System Bus Clock Enable

Value	Description
0	The corresponding MCKx is disabled.
1	The corresponding MCKx is enabled.

Bits 20:16 – CSS[4:0] Clock Source Selection
Select the clock to be applied to the selected clock to generate the corresponding MCKx.

Value	Name	Description
0	MD_SLOW_CLK	MD_SLCK is selected
1	TD_SLOW_CLOCK	TD_SLCK is selected
2	MAINCK	MAINCK is selected
3	MCK0	MCK0 is selected
4	–	Reserved
5	SYSPLL	SYSPLL is selected
6	DDRPLL	DDRPLL is selected
7	IMGPLL	IMGPLL is selected
8	BAUDPLL	BAUDPLL is selected
9	AUDIOPLL	AUDIOPLL is selected
10	ETHPLL	ETHPLL is selected

Bits 10:8 – DIV[2:0] Divisor Value
Select the division ratio to be applied to the selected clock to generate the corresponding MCKx.

Value	Name	Description
0	MASTER_DIV1	Selected clock divided by 1
1	MASTER_DIV2	Selected clock divided by 2
2	MASTER_DIV4	Selected clock divided by 4
3	MASTER_DIV8	Selected clock divided by 8
4	MASTER_DIV16	Selected clock divided by 16

Value	Name	Description
5	MASTER_DIV32	Selected clock divided by 32
6	MASTER_DIV64	Selected clock divided by 64
7	MASTER_DIV3	Selected clock divided by 3

Bit 7 – CMD Command

Value	Description
0	Read mode.
1	Write mode.

Bits 3:0 – ID[3:0] Main System Bus Clock Index
Main System Bus clock index selection from 1 to 4.

35.17.14 PMC Main XTAL Frequency Register

Name: PMC_XTALF
Offset: 0x0034
Reset: 0x00000007
Property: Read/Write

Access						R/W	R/W	R/W
Reset						1	1	1

Bits 2:0 – XTALF[2:0] Crystal Frequency
Indicates the currently used main crystal frequency to UTMI PHYs. This field must match the frequency of the implemented onboard crystal frequency.

Value	Name	Description
0	F16M	The main crystal frequency is 16 MHz.
1	–	Reserved
2	F20M	The main crystal frequency is 20 MHz.
3	F24M	The main crystal frequency is 24 MHz.
4	–	Reserved
5	F32M	The main crystal frequency is 32 MHz.
6	–	Reserved
7	–	Reserved

35.17.15 PMC Programmable Clock Register

Name: PMC_PCKx
Offset: 0x40 + x*0x04 [x=0..7]
Reset: 0
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the PMC Write Protection Mode Register.

Access				R/W	R/W	R/W	R/W	R/W
Reset				0	0	0	0	0

Bits 15:8 – PRES[7:0] Programmable Clock Prescaler

Value	Description
0-255	Selected clock is divided by PRES+1.

Bits 4:0 – CSS[4:0] Programmable Clock Source Selection
Values not listed are considered “reserved”.

Value	Name	Description
0	MD_SLOW_CLK	MD_SLCK is selected.
1	TD_SLOW_CLOCK	TD_SLCK is selected.
2	MAINCK	MAINCK is selected.
3	MCK0	MCK0 is selected.
4	–	Reserved
5	SYSPLL	SYSPLL is selected.
6	DDRPLL	DDRPLL is selected.
7	IMGPLL	IMGPLL is selected.
8	BAUDPLL	BAUDPLL is selected.
9	AUDIOPLL	AUDIOPLL is selected.
10	ETHPLL	ETHPLL is selected.

35.17.16 PMC Interrupt Enable Register

Name: PMC_IER
Offset: 0x0060
Reset: –
Property: Write-only

This register can only be written if the WPITEN bit is cleared in the PMC Write Protection Mode Register.

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Enables the corresponding interrupt.

Bit	31	30	29	28	27	26	25	24
						MCKXRDY	PLL_INT

	OSCSELS				MCKRDY			MOSCXTS
Access	R				R			R
Reset	0				1			0

Bit 26 – MCKXRDY Main System Bus Clock x [x=1..4] Ready Status

Value	Description
0	At least one main system bus clock is not established.
1	All main system bus clocks are established.

Bit 25 – PLL_INT PLL Interrupt Status

Value	Description
0	No PLL interrupt has occurred.
1	A PLL interrupt has occurred. PLL interrupt is defined by the configuration of PMC_IMR.

Bit 24 – GCLKRDY GCLK Ready

Value	Description
0	A GCLK is not ready to use (clock switching in progress).
1	All GCLKs are switched to their selected source clock and ready to use.

Bit 23 – MCKMON Main System Bus Clock0 Clock Monitor Error
This status is cleared on read.

Value	Description
0	Main system bus clock0 is correct or the CPU clock monitor is disabled.
1	Main system bus clock0 is incorrect or has been incorrect for an elapsed period of time since the monitoring has been enabled.

Bit 21 – XT32KERR Slow Crystal Oscillator Error

Value	Description
0	The frequency of the 32.768 kHz crystal oscillator is correct (32.768 kHz ±1%) or the monitoring is disabled.
1	The frequency of the 32.768 kHz crystal oscillator is incorrect or has been incorrect for an elapsed period of time since the monitoring has been enabled.

Bit 20 – FOS Clock Failure Detector Fault Output Status

Value	Description
0	The fault output of the clock failure detector is inactive.
1	The fault output of the clock failure detector is active. This status is cleared by writing a ‘1’ to FOCLR in PMC_FOCR.

Bit 19 – CFDS Clock Failure Detector Status

Value	Description
0	A clock failure of the main crystal oscillator clock is not detected.
1	A clock failure of the main crystal oscillator clock is detected.

Bit 18 – CFDEV Clock Failure Detector Event

Value	Description
0	No clock failure detection of the main crystal oscillator clock has occurred since the last read of PMC_SR.
1	At least one clock failure detection of the main crystal oscillator clock has occurred since the last read of PMC_SR.

Bit 17 – MOSCRCS Main RC Oscillator Status

Value	Description
0	Main RC oscillator is not stabilized.
1	Main RC oscillator is stabilized.

Bit 16 – MOSCSELS Main Clock Source Oscillator Selection Status

Value	Description
0	Selection is in progress.
1	Selection is done.

Bits 8, 9, 10, 11, 12, 13, 14, 15 – PCKRDYx Programmable Clock Ready Status

Value	Description
0	Programmable clock x is not ready.
1	Programmable clock x is ready.

Bit 7 – OSCSELS Timing Domain Slow Clock Oscillator Selection

Value	Description
0	Embedded slow RC oscillator is selected.
1	32.768 kHz crystal oscillator is selected.

Bit 3 – MCKRDY Main System Bus Clock 0 Status

Value	Description
0	Main system bus clock 0 is not ready.
1	Main system bus clock 0 is ready.

Bit 0 – MOSCXTS Main Crystal Oscillator Status

Value	Description
0	Main crystal oscillator is not stabilized.
1	Main crystal oscillator is stabilized.

35.17.19 PMC Interrupt Mask Register

Name: PMC_IMR
Offset: 0x006C
Reset: 0x00000000
Property: Read-only

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Enables the corresponding interrupt.

Bit	31	30	29	28	27	26	25	24

Access								
Reset								

Bit	7	6	5	4	3	2	1	0
Access								
Reset								

Bits 24, 25 – WLANx Wake-Up on LAN[x]

Value	Description
0	The Wake-up on LAN[x] alarm has no effect on the PMC.
1	The Wake-up on LAN[x] alarm enables a fast restart signal to the PMC.

Bit 19 – HSDHC HSDHC Alarm

Value	Description
0	The HSDHC alarm has no effect on the PMC.
1	The HSDHC alarm enables a fast restart signal to the PMC.

Bit 18 – USBAL USB Alarm Enable

Value	Description
0	The USB alarm has no effect on the PMC.
1	The USB alarm enables a fast restart signal to the PMC.

Bit 17 – RTCAL RTC Alarm Enable

Value	Description
0	The RTC alarm has no effect on the PMC.
1	The RTC alarm enables a fast restart signal to the PMC.

Bit 16 – RTTAL RTT Alarm Enable

Value	Description
0	The RTT alarm has no effect on the PMC.
1	The RTT alarm enables a fast restart signal to the PMC.

35.17.21 PMC Wake-Up Control Register

Name: PMC_WCR
Offset: 0x0074
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24

Reset	0	0	0	0	0	0	0	0

Bit 24 – CMD Command

Value	Description
0	Read mode.
1	Write mode.

Bit 17 – WIP Wake-Up Input Polarity
Defines the active polarity of the selected wake-up input. If the corresponding wake-up input is enabled at the FSTP level, it enables a fast restart signal.

Value	Description
0	Active polarity is low.
1	Active polarity is high.

Bit 16 – EN Wake-Up Input Enable

Value	Description
0	The selected wake-up input has no effect on the PMC.
1	The selected wake-up input enables a fast restart signal to the PMC.

Bits 7:0 – WKPIONB[7:0] Wake-Up Input Number
Defines which wake-up source is to be modified during a write access (CMD is set to '1') or which wake-up source status is read on the next read access to this register (CMD is set to '0').

Primary Signal Name	WKPIONB
PAn	n
PBn	n + 32
PCn	n + 64
PDn	n + 96
PEn	n + 128

35.17.22 PMC Fault Output Clear Register

Name: PMC_FOCR
Offset: 0x0078
Reset: –
Property: Write-only

Access	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
							WPITEN	WPEN
Access							R/W	R/W
Reset							0	0

Bits 31:8 – WPKEY[23:0] Write Protection Key

Value	Name	Description
0x504D43	PASSWD	Writing any other value in this field aborts the write operation of the WPEN bit. Always reads as 0.

Bit 1 – WPITEN Write Protection Interrupt Enable
See Register Write Protection for the list of registers that can be write-protected.

Value	Description
0	Disables the write protection on interrupt registers if WPKEY corresponds to 0x504D43 (“PMC” in ASCII).
1	Enables the write protection on interrupt registers if WPKEY corresponds to 0x504D43 (“PMC” in ASCII).

Bit 0 – WPEN Write Protection Enable
See Register Write Protection for the list of registers that can be write-protected.

Value	Description
0	Disables the write protection if WPKEY corresponds to 0x504D43 (“PMC” in ASCII).
1	Enables the write protection if WPKEY corresponds to 0x504D43 (“PMC” in ASCII).

35.17.24 PMC Write Protection Status Register

Name: PMC_WPSR
Offset: 0x0084
Reset: 0x00000000
Property: Read-only

Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
								WPVS
Access								R
Reset								0

Bits 23:8 – WPVSRC[15:0] Write Protection Violation Source
When WPVS = 1, WPVSRC indicates the register address offset at which a write access has been attempted.

Bit 0 – WPVS Write Protection Violation Status

Value	Description
0	No write protection violation has occurred since the last read of the PMC_WPSR.
1	A write protection violation has occurred since the last read of the PMC_WPSR. If this violation is an unauthorized attempt to write a protected register, the associated violation is reported into field WPVSRC.

35.17.25 PMC Peripheral Control Register

Name: PMC_PCR
Offset: 0x0088
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
	CMD		GCLKEN	EN	GCLKDIV[7:4]			
Access	R/W		R/W	R/W	R/W	R/W	R/W	R/W

		PID[6:0]						
Access		R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset		0	0	0	0	0	0	0

Bit 31 – CMD Command

Value	Description
0	Read mode.
1	Write mode.

Bit 29 – GCLKEN Generic Clock Enable

Value	Description
0	The selected generic clock is disabled.
1	The selected generic clock is enabled.

Bit 28 – EN Enable

Value	Description
0	The selected peripheral clock is disabled.
1	The selected peripheral clock is enabled.

Bits 27:20 – GCLKDIV[7:0] Generic Clock Division Ratio
Generic clock is the selected clock period divided by GCLKDIV + 1.
GCLKDIV must not be changed while the peripheral selects GCLKx (bit rate, etc.).

Bits 19:16 – MCKID[3:0] Main System Bus Clock Index (Read-only)
Main system bus clock index of the selected peripheral. Each peripheral is associated to one main system bus clock. It is not possible to modify this value.

Bits 12:8 – GCLKCSS[4:0] Generic Clock Source Selection

Value	Name	Description
0	MD_SLOW_CLK	MD_SLCK is selected.
1	TD_SLOW_CLOCK	TD_SLCK is selected.
2	MAINCK	MAINCK is selected.
3	MCK0	MCK0 is selected.

Value	Name	Description
4	–	Reserved
5	SYSPLL	SYSPLL is selected.
6	DDRPLL	DDRPLL is selected.
7	IMGPLL	IMGPLL is selected.
8	BAUDPLL	BAUDPLL is selected.
9	AUDIOPLL	AUDIOPLL is selected.
10	ETHPLL	ETHPLL is selected.

Bits 6:0 – PID[6:0] Peripheral ID
Peripheral ID selection.
Not all GCLK inputs are available on all peripherals.
Refer to identifier definitions in the table “Peripheral Identifiers”.

35.17.26 PMC Asynchronous Partial Wake-Up Activity In Progress Register

Name: PMC_SLPWK_AIPR
Offset: 0x0090
Reset: –
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16

Access								
Reset								

Bit	7	6	5	4	3	2	1	0
								AIP
Access								R
Reset								–

Bit 0 – AIP Activity In Progress
Only the following PIDs can be configured with asynchronous partial wake-up: FLEXCOMx and ADCC.

Value	Description
0	There is no activity on peripherals. The asynchronous partial wake-up function can be activated on one or more peripherals. The device can enter ULP1 or ULP2 mode.
1	One or more peripherals are currently active. The device must not enter ULP1 or ULP2 mode. if the asynchronous partial wake-up is enabled for one of the following PIDs: FLEXCOMx and ADCC.

35.17.27 PMC Asynchronous Partial Wake-Up Control Register

Name: PMC_SLPWKCR
Offset: 0x0094
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the PMC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
				SLPWKSR				
Access				R/W

Reset		0	0	0	0	0	0	0

Bit 28 – SLPWKSR Asynchronous Partial Wake-Up Sleep Register
Not all PIDs can be configured with asynchronous partial wake-up.
Only the following PIDs can be configured with asynchronous partial wake-up: FLEXCOMx and ADCC.

Value	Description
0	The asynchronous partial wake-up function of the peripheral is disabled.
1	The asynchronous partial wake-up function of the peripheral is enabled.

Bit 16 – ASR Activity Status Register
Not all PIDs can be configured with asynchronous partial wake-up.
Only the following PIDs can be configured with asynchronous partial wake-up: FLEXCOMx and ADCC.

Value	Description
0	The peripheral x is not currently active; the asynchronous partial wake-up function can be activated.
1	The peripheral x is currently active; the asynchronous partial wake-up function must not be activated.

Bit 12 – CMD Command

Value	Description
0	Read mode.
1	Write mode.

Bits 6:0 – PID[6:0] Peripheral ID
Peripheral ID selection from PID2 to the maximum PID number. This refers to identifiers as defined in the table "Peripheral Identifiers".

35.17.28 PMC MCK0 Monitor Limits Register

Name: PMC_MCKLIM
Offset: 0x009C
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
	MCK_HIGH_RES[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0
Bit	23	22	21	20	19	18	17	16

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 31:24 – MCK_HIGH_RES[7:0] MCK0 Monitoring High Reset Limit
Beyond this limit, the MCK0 frequency monitor generates a reset.

Bits 23:16 – MCK_LOW_RES[7:0] MCK0 Monitoring Low RESET Limit
Below this limit, the MCK0 frequency monitor generates a reset.

Bits 15:8 – MCK_HIGH_IT[7:0] MCK0 Monitoring High IT Limit
Beyond this limit, the MCK0 frequency monitor generates an interrupt.

Bits 7:0 – MCK_LOW_IT[7:0] MCK0 Monitoring Low IT Limit
Below this limit, the MCK0 frequency monitor generates an interrupt.

35.17.29 PMC Peripheral Clock Status Register 0

Name: PMC_CSR0
Offset: 0x00A0
Reset: 0x00000000
Property: Read-only

"PIDx" refers to identifiers as defined in the table "Peripheral Identifiers".

The following configuration values are valid for all listed bit names of this register:

0: The corresponding peripheral clock is disabled.

1: The corresponding peripheral clock is enabled.

1	PLL encountered an overflow.

Bits 0, 1, 2, 3, 4, 5, 6 – UDRx PLLx Underflow

Value	Description
0	PLL is not in Underflow state.
1	PLL encountered an underflow.

36. Parallel Input/Output Controller (PIO)

36.1 Description

The Parallel Input/Output Controller (PIO) manages up to 136 fully programmable input/output lines. Each I/O line may be dedicated as a general purpose I/O or be assigned to a function of an embedded peripheral. This ensures effective optimization of the pins of the product.

The PIO Controller features a synchronous output providing up to 32 bits of data output in a single write operation.

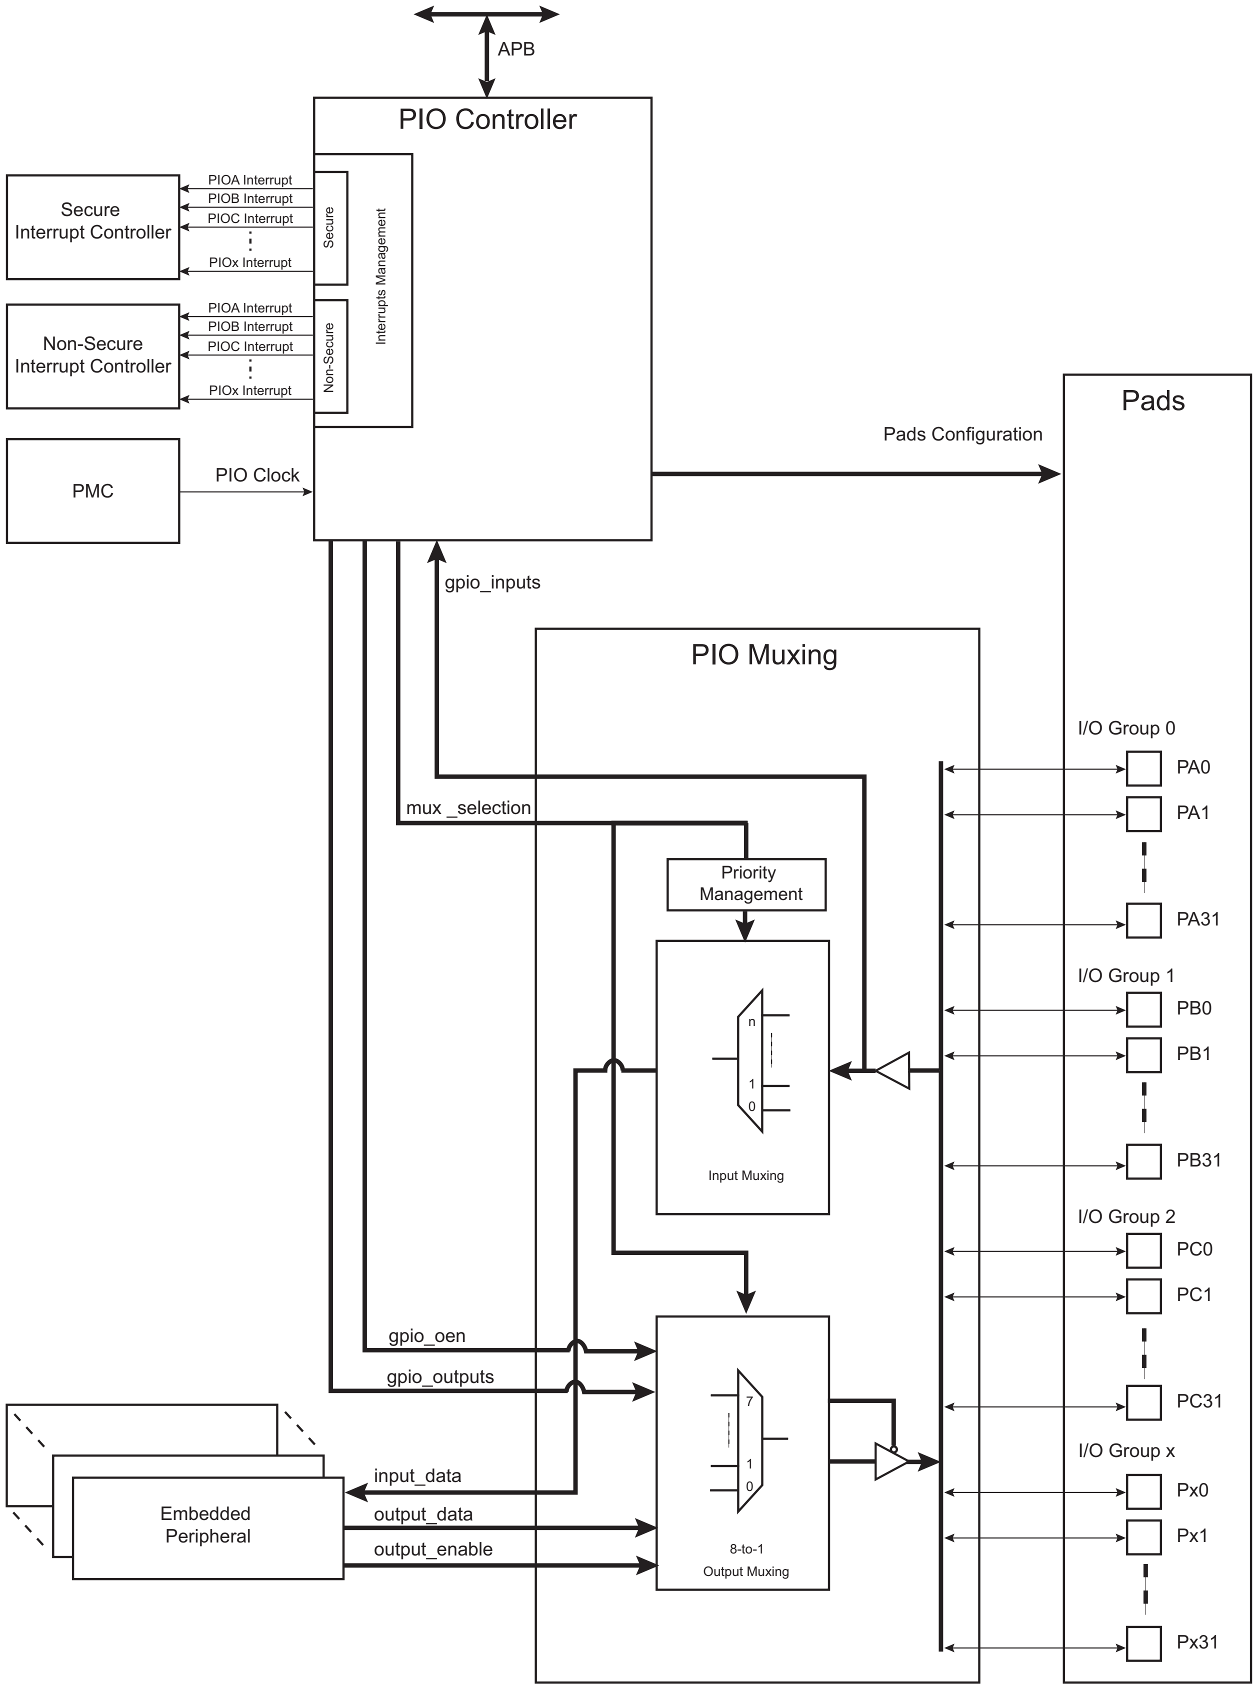
The PIO embeds safety and security features.

36.2 Embedded Characteristics

- Up to 136 Programmable I/O Lines
- Multiplexing of Up to 7 Peripheral Functions per I/O Line
- For Each I/O Line (whether assigned to a peripheral or used as general purpose I/O):
  - Input change interrupt
  - Programmable glitch filter
  - Programmable debouncing filter
  - Multi-drive option enables driving in open drain
  - Programmable pull-up/pull-down
  - Pin data status register, supplies visibility of the level on the pin at any time
  - Programmable event: rising edge, falling edge, both edges, low-level or high-level
  - Configuration lock by the connected peripheral
  - Secure or Non-Secure management
  - Programmable configuration lock (active until next V_{DDCORE} reset) to protect against further software modifications (intentional or unintentional)
  - Programmable freeze on tamper event for each I/O line configuration
- Register Write Protection against Unintentional Software Modifications:
  - One configuration bit to enable or disable protection of I/O line settings
  - One configuration bit to enable or disable protection of interrupt settings
- Synchronous Output, Possibility to Set or Clear Simultaneously Up to 32 I/O Lines in a Single Write
- Programmable Schmitt Trigger Inputs
- Programmable Slew Rate

36.3 Block Diagram

Figure 36-1. PIO Controller Block Diagram



Notes:
1. x = 4 (the number of I/O groups is 5).
2. n depends on the number of I/O lines affected to the IP input.

36.4 Product Dependencies

36.4.1 Pin Multiplexing

Each pin is configurable, depending on the product, as either a general purpose I/O line only, or as an I/O line multiplexed with up to 7 peripheral I/Os. As the multiplexing is hardware defined and thus product-dependent, the hardware designer and programmer must carefully determine the configuration of the PIO Controllers required by their application. When an I/O line is general purpose only, i.e., not multiplexed with any peripheral I/O, programming of the PIO Controller regarding the assignment to a peripheral has no effect and only the PIO Controller can control how the pin is driven by the product.

36.4.2 External Interrupt Lines

The interrupt signals IRQ0 to IRQn are multiplexed through the PIO Controllers.

36.4.3 Power Management

The Power Management Controller (PMC) controls the PIO Controller clock in order to save power. Writing any of the registers of the user interface does not require the PIO Controller clock to be enabled. This means that the configuration of the I/O lines does not require the PIO Controller clock to be enabled.

However, when the clock is disabled, not all of the features of the PIO Controller are available, including glitch filtering. Note that the input change interrupt, the interrupt modes on a programmable event and the read of the pin level require the clock to be validated.

After a hardware reset, the PIO clock is disabled by default.

The user must configure the PMC before any access to the input line information.

36.4.4 Interrupt Generation

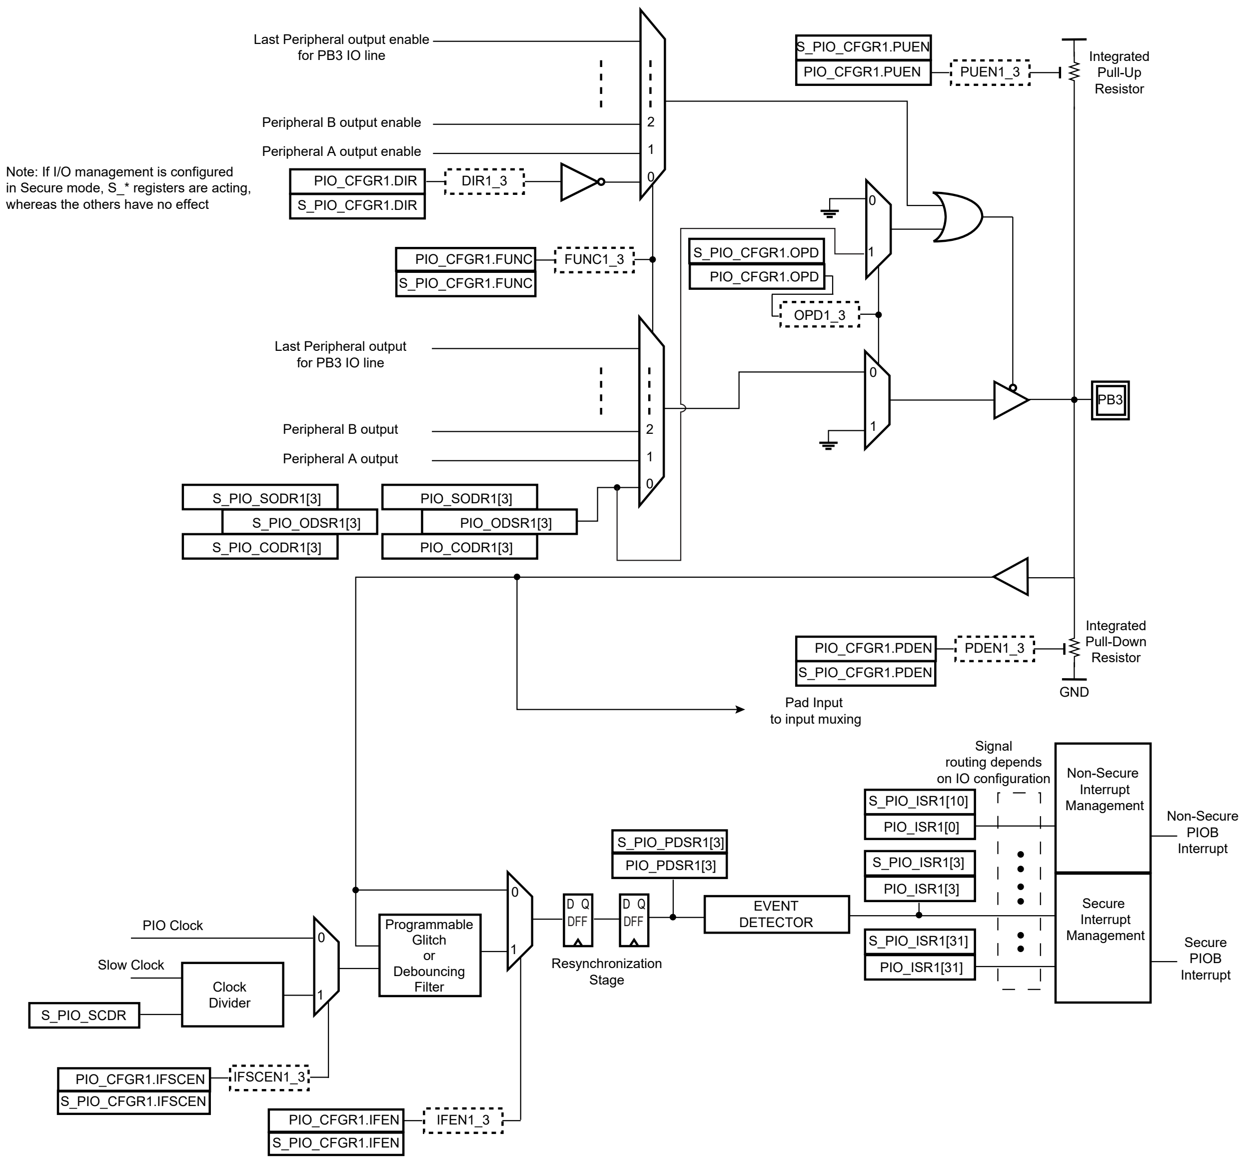
For interrupt handling, the PIO Controllers are considered as user peripherals. This means that the PIO Controller interrupt lines are connected among the interrupt sources. The PIO Controller supplies one interrupt signal per I/O group. Refer to the PIO Controller peripheral identifier in the product description to identify the interrupt sources dedicated to the PIO Controller. The PIO Controller can target either the Secure or Non-Secure Interrupt Controller according to security level of the I/O line which triggers the interruption. Using the PIO Controller requires the Interrupt Controller to be programmed first.

The PIO Controller interrupt can be generated only if the PIO Controller clock is enabled.

36.5 Functional Description

The PIO Controller features up to 512 fully-programmable I/O lines. Most of the control logic associated to each I/O is represented in the following figure, where the I/O line 3 of the PIOB (PB3) is described as an example. In this description each signal shown represents one of up to 512 possible indexes.

Figure 36-2. I/O Line Control Logic



36.5.1 I/O Line Configuration Method

The user interface of the PIO Controller provides several sets of registers. Each set of registers interfaces with one I/O group.

Table 36-1. I/O Group List

I/O Group Number	PIO
0	PIOA
1	PIOB
...	...
4	PIOE

36.5.1.1 Security Management

The user must first define the security level of the I/O line. Each I/O line of each I/O group must be defined as either secure or non-secure lines. Each I/O line of the I/O group x can be set as non-secure I/O line by writing a 1 to the corresponding bit P0–P31 of the Secure PIO Set I/O Non-Secure register (S_PIO_SIONRx) of the I/O group x.

To define an I/O line of I/O group x as a secure I/O line, write a 1 to the corresponding bit P0–P31 of the Secure PIO Set I/O Secure register (S_PIO_SIOSRx) of the I/O group x.

Examples:

Setting the I/O line PC4 as a non-secure line:

- Write the value 16 (bit 4 at 1) at address 0x10B0 (S_PIO_SIONR2)

Setting the I/O line PB3 as a secure line:

- Write the value 8 (bit 3 at 1) at address 0x1074 (S_PIO_SIOSR1)

The security level of each I/O line is reported by the Secure PIO I/O Security Status register (S_PIO_IOSSRx) of the corresponding I/O group. Reading 0 at the corresponding bit P0–P31 means that the corresponding I/O line of the I/O group is defined as secure. Reading 1 means that this I/O line of the I/O group is non-secure.

The PIO Controller user interface is divided into two register mapping areas:

- The Non-Secure area, located from address 0x0 to 0x1000, can be accessed by any (secure or non-secure) host. This area interfaces with all the I/O lines defined as non-secure. Trying to access to an I/O line defined as secure through this area will have no effect on the I/O line and the read values will be 0.
- The Secure area, located above address 0x1000, can only be accessed by a secure host (if the PIO Controller is defined as secure at the HMATRIX level). This area interfaces with all the I/O lines defined as secure. Trying to access to an I/O line defined as non-secure through this area will have no effect on the I/O line and the read values will be 0.

36.5.1.2 Programming I/O Line Configuration

The user must first define which I/O line in the group will be targeted by writing a 1 to the corresponding bit in the PIO Mask Register (PIO_MSKRx). Several I/O lines in an I/O group can be configured at the same time by setting the corresponding bits in PIO_MSKRx. Then, writing the PIO Configuration Register (PIO_CFGRx) apply the configuration to the I/O line(s) defined in PIO_MSKRx. All the I/O lines defined as secure in the S_PIO_SIOSRx must be configured by writing the S_PIO_CFGRx and S_PIO_MSKRx registers.

For more details concerning the I/O line configuration using PIO_MSKRx and PIO_CFGRx, see section I/O Lines Programming Example.

36.5.1.3 Reading the I/O Line Configuration

As for programming operation, reading configuration requires the user to first define which I/O line in the group x will be targeted by writing a 1 to the corresponding bit in the PIO_MSKRx. The value of the targeted I/O line is read in PIO_CFGRx.

If several bits are set in PIO_MSKRx, then the read configuration in PIO_CFGRx is the configuration of the I/O line with the lowest index.

Note that S_PIO_MSKRx and S_PIO_CFGRx must be used to read the configuration of a secure I/O line.

36.5.2 Pull-Up and Pull-Down Resistor Control

Each I/O line is designed with an embedded pull-up resistor and an embedded pull-down resistor.

The pull-up resistor on the I/O line(s) defined in PIO_MSKRx can be enabled by setting the PUEN bit in PIO_CFGRx. Clearing the PUEN bit in PIO_CFGRx disables the pull-up resistor of I/O lines defined in PIO_MSKRx.

The pull-down resistor on the I/O line(s) defined in PIO_MSKRx can be enabled by setting the PDEN bit in PIO_CFGRx. Clearing the PDEN bit in PIO_CFGRx disables the pull-down resistor of I/O lines defined in PIO_MSKRx.

If both PUEN and PDEN bits are set in PIO_CFGRx, only the pull-up resistor is enabled for I/O line(s) defined in PIO_MSKRx and the PDEN bit is discarded.

Control of the pull-up resistor is possible regardless of the configuration of the I/O line (Input, Output, Open-drain).

Note that S_PIO_MSKRx and S_PIO_CFGRx must be used to program the pull-up or pull-down configuration of a secure I/O line.

For more details concerning Pull-up and Pull-down configuration, see PIO_CFGRx or S_PIO_CFGRx for secure I/O line configuration.

The reset value of PUEN and PDEN bits of each I/O line is defined at the product level and depends on the multiplexing of the device.

36.5.3 General Purpose or Peripheral Function Selection

The PIO Controller provides multiplexing of up to 7 peripheral functions on a single pin. The selection is performed by writing the FUNC field in PIO_CFGRx. The selected function is applied to the I/O line(s) defined in PIO_MSKRx.

When FUNC is 0, no peripheral is selected and the General Purpose PIO (GPIO) mode is selected (in this mode, the I/O line is controlled by the PIO Controller).

When the value configured in PIO_CFGRx.FUNC is greater than 0, the software cannot drive the I/O line anymore and the value configured in PIO_CFGRx.FUNC defines which embedded peripheral drives the I/O lineFor more details, refer to the table Pin Description in section Package and Pinout.

Note that S_PIO_MSKRx and S_PIO_CFGRx must be used to program the FUNC field of a secure I/O line.

For more details, see PIO_CFGRx or S_PIO_CFGRx for secure I/O line configuration.

Note that multiplexing of peripheral lines affects both input and output peripheral lines. When a peripheral is not selected on any I/O line, its inputs are assigned with constant default values defined at the product level. The user must ensure that only one I/O line is affected to a peripheral input at a time.

The reset value of the FUNC field of each I/O line is defined at the product level and depends on the multiplexing of the device.

36.5.4 Output Control

When the I/O line is assigned to a peripheral function, i.e., the corresponding FUNC field of the line configuration is 1, the drive of the I/O line (direction, output value) is controlled by the peripheral.

When the FUNC field of a I/O line is 0, then the I/O line is set in General Purpose mode and the I/O line can be configured to be driven by the PIO Controller (software) instead of the peripheral.

If PIO_CFGRx/S_PIO_CFGRx/.DIR is configured in Output mode and PIO_CFGRx/S_PIO_CFGRx/.FUNC=0, then the I/O line can be driven by the PIO Controller. The level driven on an I/O line can be determined by writing in the PIO Set Output Data Register (PIO_SODRx)/Secure PIO Set Output Data Register (S_PIO_SODRx)/ and the PIO Clear Output Data Register (PIO_CODRx)Secure PIO Clear Output Data Register (S_PIO_CODRx)/. These write operations, respectively, set and clear the PIO Output Data Status Register (PIO_ODSRx)/Secure PIO Output Data Status Register (S_PIO_ODSRx)/, which represents the data driven on the I/O lines. Writing PIO_ODSRx/ S_PIO_ODSRx directly is possible and only affects the I/O line set to 1 in PIO_MSKRx/S_PIO_MSKRx (see Synchronous Data Output).

When DIR of the I/O line configuration is at zero, the corresponding I/O line is used as an input only.

DIR has no effect if the corresponding line is assigned to a peripheral function, but writing DIR is managed whether the pin is configured to be controlled by the PIO Controller or assigned to a peripheral function. This enables configuration of the I/O line prior to setting it to be managed by the PIO Controller.

Similarly, writing in PIO_SODRx/S_PIO_SODRx and PIO_CODRx/S_PIO_CODRx affects PIO_ODSRx/ S_PIO_ODSRx. This is important as it defines the first level driven on the I/O line.

36.5.5 Synchronous Data Output

Clearing one or more PIO line(s) and setting another one or more PIO line(s) synchronously cannot be done by using PIO_SODRx/S_PIO_SODRx and PIO_CODRx/S_PIO_CODRx. It requires two successive write operations into two different registers. To overcome this, the PIO Controller offers a direct control of PIO outputs by single write access to PIO_ODSRx/S_PIO_ODSRx. Only I/O lines set to 1 in PIO_MSKRx/S_PIO_MSKRx are written.

36.5.6 Open-Drain Mode

Each I/O can be independently programmed in Open-Drain mode. This feature permits several drivers to be connected on the I/O line which is driven low only by each device. An external pull-up resistor (or enabling of the internal one) is generally required to ensure a high level on the line.

The Open-Drain mode is controlled by the OPD bit in the I/O line configuration (PIO_CFGRx or S_PIO_CFGRx). An I/O line is switched in Open-Drain mode by setting the PIO_CFGRx/S_PIO_CFGRx.OPD bit. The Open-Drain mode can be selected if the I/O line is not controlled by a peripheral (the FUNC field must be cleared in PIO_CFGRx/S_PIO_CFGRx).

For more details concerning the Open-Drain mode, see PIO_CFGRx or S_PIO_CFGRx for secure I/O line configuration.

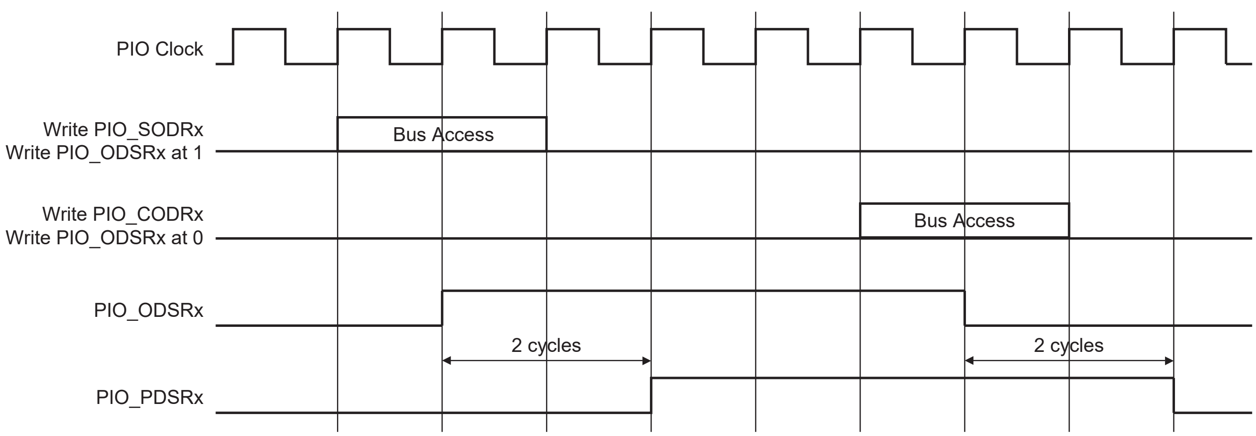
After reset, the OPD bit of each I/O line is defined at the product level and depends on the multiplexing of the device.

Note: Open-drain capability is not possible when the I/O line is driven by a peripheral. Only software control (GPIO mode) is able to manage the open-drain for an I/O line. TWI is able to manage open-drain because this peripheral does not require the PIO to be configured in Open-drain mode.

36.5.7 Output Line Timings

The figure below shows how the outputs are driven either by writing PIO_SODRx/S_PIO_SODRx or PIO_CODRx/S_PIO_CODRx, or by directly writing PIO_ODSRx/S_PIO_ODSRx. This last case is valid only if the corresponding bit in PIO_MSKRx/S_PIO_MSKRx is set. The figure also shows when the feedback in the Pin Data Status register (PIO_PDSRx/S_PIO_PDSRx) is available.

Figure 36-3. Output Line Timings



36.5.8 Inputs

The level on each I/O line of the I/O group x can be read through PIO_PDSRx/S_PIO_PDSRx. This register indicates the level of the I/O lines regardless of their configuration, whether uniquely as an input, or driven by the PIO Controller, or driven by a peripheral.

Reading the I/O line levels requires the clock of the PIO Controller to be enabled, otherwise PIO_PDSRx/S_PIO_PDSRx reads the levels present on the I/O line at the time the clock was disabled.

36.5.9 Input Glitch and Debouncing Filters

Optional input glitch and debouncing filters are independently programmable on each I/O line.

The glitch filter can filter a glitch with a duration of less than 1 peripheral clock and the debouncing filter can filter a pulse of less than 1 period of a programmable divided slow clock.

The selection between glitch filtering or debounce filtering is done by writing the PIO_CFGR.IFSCEN. The selected filtering mode is applied to the I/O line(s) defined in PIO_MSKRx.

- If IFSCEN = 0: The glitch filter can filter a glitch with a duration of less than 1 peripheral clock period.
- If IFSCEN = 1: The debouncing filter can filter a pulse with a duration of less than 1 programmable divided slow clock period.

For the debouncing filter, the period of the divided slow clock is performed by writing in the DIV field of the Secure PIO Slow Clock Divider Debouncing Register (S_PIO_SCDR): $t_{div\_slck} = ((DIV + 1) \times 2) \times t_{slck}$.

When the glitch or debouncing filter is enabled, a glitch or pulse with a duration of less than 1 selected clock cycle (selected clock represents PIO clock or divided slow clock depending on IFSCEN configuration) is automatically rejected. A pulse of a duration equal to 1 clock cycle may be filtered or not depending on the clock jitter.

The filters also introduce some latencies, illustrated in the figures below .

The glitch filter of each I/O line is controlled by PIO_CFGR.IFEN. Setting PIO_CFGRx.IFEN enables the glitch filter of the I/O line(s) defined in PIO_MSKRx.

When the glitch and/or debouncing filter is enabled, it does not modify the behavior of the inputs on the peripherals. It acts only on the value read in PIO_PDSRx and on the input change interrupt detection. The glitch and debouncing filters require that the PIO Controller clock is enabled.

Figure 36-4. Input Glitch Filter Timing

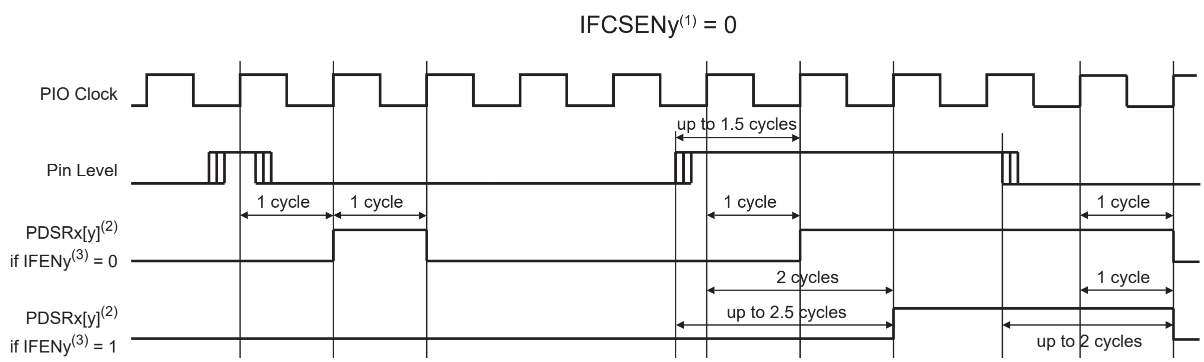


Figure 36-5. Input Debouncing Filter Timing

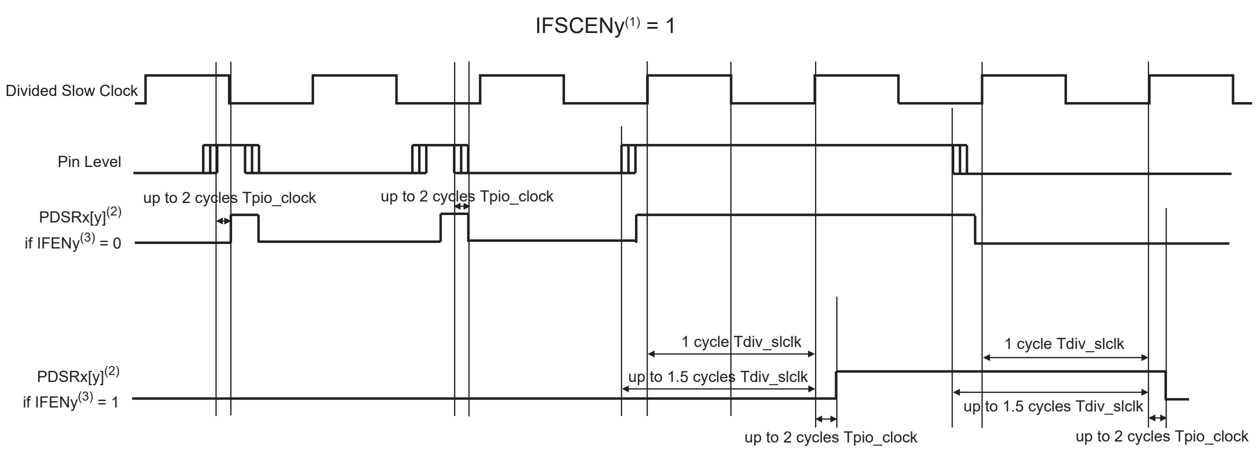


Note:

1. Means IFCSEN of the I/O line y of the I/O group x.
2. Means PIO Data Status value of the I/O line y of the I/O group x.
3. Means IFEN of the I/O line y of the I/O group x.

36.5.10 Input Edge/Level Interrupt

Each I/O group can be programmed to generate an interrupt when it detects an edge or a level on an I/O line. The Input Edge/Level interrupts are controlled by writing the PIO Interrupt Enable Register (PIO_IERx) and the PIO Interrupt Disable Register (PIO_IDRx), which enable and disable the input change interrupt respectively by setting and clearing the corresponding bit in the PIO Interrupt Mask Register (PIO_IMRx). For the Secure I/O lines, the Input Edge/Level interrupts are controlled by writing S_PIO_IERx and S_PIO_IDRx, which enable and disable input change interrupts respectively by setting and clearing the corresponding bit in the S_PIO_IMRx. As input change detection is possible only by comparing two successive samplings of the input of the I/O line, the PIO Controller clock must be enabled. The Input Change interrupt is available regardless of the configuration of the I/O line, i.e., configured as an input only, controlled by the PIO Controller or assigned to a peripheral function.

Each I/O group can generate a Non-Secure interrupt and a Secure interrupt according to the security level of the I/O line which triggers the interrupt.

According to the EVTSEL field value in PIO_CFGRx or S_PIO_CFGRx in case of a Secure I/O line, the interrupt signal of the I/O group x can be generated on the following occurrence:

- (S_)PIO_CFGRx.EVTSELy = 0: The interrupt signal of the I/O group x is generated on the I/O line y falling edge detection (assuming that (S_)PIO_IMRx[y] = 1).
- (S_)PIO_CFGRx.EVTSELy = 1: The interrupt signal of the I/O group x is generated on the I/O line y rising edge detection (assuming that (S_)PIO_IMRx[y] = 1).
- (S_)PIO_CFGRx.EVTSELy = 2: The interrupt signal of the I/O group x is generated on the I/O line y both rising and falling edge detection (assuming that (S_)PIO_IMRx[y] = 1).
- (S_)PIO_CFGRx.EVTSELy = 3: The interrupt signal of the I/O group x is generated on the I/O line y low level detection (assuming that (S_)PIO_IMRx[y] = 1).
- (S_)PIO_CFGRx.EVTSELy = 4: The interrupt signal of the I/O group x is generated on the I/O line y high level detection (assuming that (S_)PIO_IMRx[y] = 1).

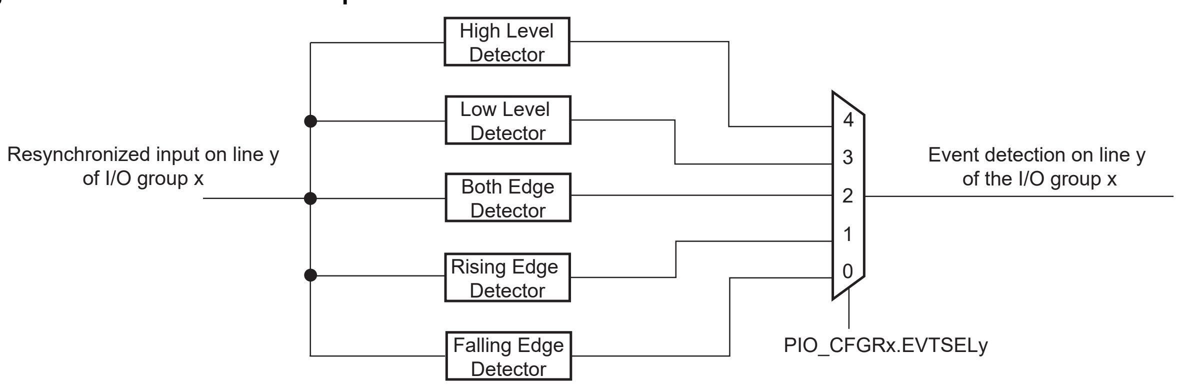
By default, the interrupt can be generated at any time a falling edge is detected on the input.

When an input edge or level is detected on an I/O line, the corresponding bit in the PIO Interrupt Status Register (PIO_ISRx), or in the Secure PIO Interrupt Status Register (S_PIO_ISRx) if the I/O line is Secure, is set.

For a Non-Secure I/O line, if the corresponding bit in PIO_IMRx is set, the Non-Secure interrupt line of the I/O group x is asserted. For a Secure I/O line, if the corresponding bit in S_PIO_IMRx is set, the Secure interrupt line of the I/O group x is asserted.

When the software reads PIO_ISRx, all the Non-Secure interrupts of the I/O group x are automatically cleared. When the software reads S_PIO_ISRx, all the Secure interrupts of the I/O group x are automatically cleared. This signifies that all the interrupts that are pending when PIO_ISRx or S_PIO_ISRx are read must be handled. When an interrupt is enabled on a “level”, the interrupt is generated as long as the interrupt source is not cleared, even if some read accesses in PIO_ISRx or S_PIO_ISRx are performed.

Figure 36-6. Event Detector on Input Lines



Example of interrupt generation on following lines:

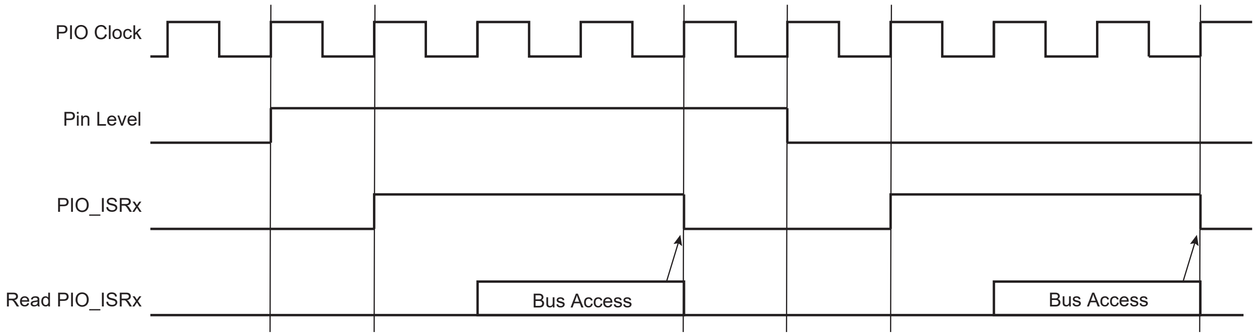
- Rising edge on the Secure PIO line 0 of the I/O group 0 (PIOA)
- Low-level edge on the Secure PIO line 1of the I/O group 0 (PIOA)
- Rising edge on the Secure PIO line 2 of the I/O group 0 (PIOA)
- High-level on the Secure PIO line 3 of the I/O group 0 (PIOA)
- Low-level on the Non-Secure PIO line 4 of the I/O group 0 (PIOA)
- High-level on the Secure PIO line 0 of the I/O group 1 (PIOB)
- Falling edge on the Secure PIO line 1 of the I/O group 1 (PIOB)
- Rising edge on the Secure PIO line 2 of the I/O group 1 (PIOB)
- Any edge on the other Non-Secure lines of the I/O group 1 (PIOB)

The table below details the required configuration for this example.

Table 36-2. Configuration for Example Interrupt Generation

Configuration	Name
PIOA: I/O Line Security Level	Define the I/O lines 0 to 3 of the PIOA as Secure by writing 32’h0000_000F in the S_PIO_SIOSR0 (offset 0x1034) Define the I/O lines 4 of the PIOA as Non-Secure by writing 32’h0000_0010 in the S_PIO_SIONR0 (offset 0x1030)
PIOA: Interrupt Mode	Enable interrupt sources for lines 0 to 3 of PIOA by writing 32’h0000_000F in S_PIO_IER0 (offset 0x1020) Enable interrupt source for the line 4 of PIOA by writing 32’h0000_0010 in PIO_IER0 (offset 0x20)
PIOA: Event Selection	Configure Rising Edge detection for Secure lines 0 and 2: Write 32’h0000_0005 in S_PIO_MSKR0 (offset 0x1000) Write 32’h0100_0000 in S_PIO_CFGR0 (offset 0x1004)
	Configure Low Level detection for Secure line 1: Write 32’h0000_0002 in S_PIO_MSKR0 (offset 0x1000) Write 32’h0300_0000 in S_PIO_CFGR0 (offset 0x1004)
	Configure High Level detection for Secure line 3: Write 32’h0000_0008 in S_PIO_MSKR0 (offset 0x1000) Write 32’h0400_0000 in S_PIO_CFGR0 (offset 0x1004)
	Configure Low Level detection for Non-Secure line 4: Write 32’h0000_0010 in PIO_MSKR0 (offset 0x0) Write 32’h0300_0000 in PIO_CFGR0 (offset 0x4)
PIOB: I/O Line Security Level	Define the I/O lines 0 to 2 of the PIOB as Secure by writing 32’h0000_0007 in the S_PIO_SIOSR1 (offset 0x1074) Define the other I/O lines of the PIOB as Non-Secure by writing 32’hFFFF_FFF8 in the S_PIO_SIONR1 (offset 0x1070)
PIOB: Interrupt Mode	Enable interrupt sources for lines 0 to 2 of PIOB by writing 32’h0000_0007 in S_PIO_IER1 (offset 0x1060) Enable interrupt sources for all other lines of PIOB by writing 32’hFFFF_FFF8 in PIO_IER1 (offset 0x60)
PIOB: Event Selection	Configure High Level detection for Secure line 0: Write 32’h0000_0001 in S_PIO_MSKR1 (offset 0x1040) Write 32’h0400_0000 in S_PIO_CFGR1 (offset 0x1044)
	Configure Falling Edge detection for Secure line 1: Write 32’h0000_0002 in S_PIO_MSKR1 (offset 0x1040) Write 32’h0000_0000 in S_PIO_CFGR1 (offset 0x1044)
	Configure Rising Edge detection for Secure line 2: Write 32’h0000_0004 in S_PIO_MSKR1 (offset 0x1040) Write 32’h0100_000 in S_PIO_CFGR1 (offset 0x1044)
	Configure Low Level detection for Non-Secure lines: Write 32’hFFFF_FFF8 in PIO_MSKR1 (offset 0x40) Write 32’h0200_000 in PIO_CFGR1 (offset 0x44)

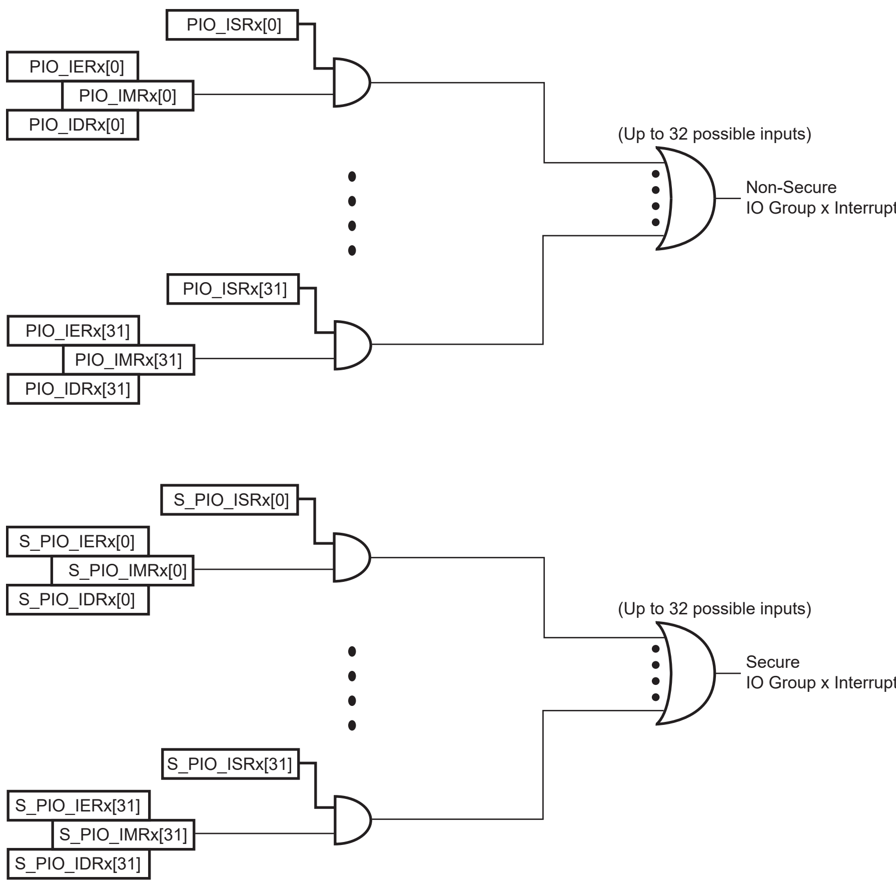
Figure 36-7. Input Change Interrupt Timings When No Additional Interrupt Modes



36.5.11 Interrupt Management

The PIO Controller can drive one secure interrupt signal and one non-secure interrupt signal per I/O group (refer to the Block Diagram). Secure interrupt signals are connected to the secure interrupt controller of the system. Non-secure interrupt signals are connected to the non-secure interrupt controller of the system.

Figure 36-8. PIO Interrupt Management



36.5.12 I/O Lines Lock

When an I/O line is controlled by a peripheral (particularly the Pulse Width Modulation Controller PWM), it can become locked by the action of this peripheral via an input of the PIO Controller. When an I/O line is locked, the following fields in PIO_CFGRx/S_PIO_CFGRx are locked and cannot be modified:

- FUNC: Peripheral selection cannot be changed when the corresponding I/O line is locked.
- PUEN: Pull-Up configuration cannot be changed when the corresponding I/O line is locked.

- PDEN: Pull-Down configuration cannot be changed when the corresponding I/O line is locked.
- OPD: Open Drain configuration cannot be changed when the corresponding I/O line is locked.

Writing to one of these fields while the corresponding I/O line is locked will have no effect.

The user can know at anytime which I/O line is locked by reading the PIO Lock Status Register (PIO_LOCKSR) or Secure PIO Lock Status Register (S_PIO_LOCKSR) for locked Secure I/O lines. Once an I/O line is locked, the only way to unlock it is to apply a hardware reset to the PIO Controller.

36.5.13 Programmable I/O Drive

It is possible to configure the I/O drive for pads PA0 to PE7. The I/O drive of the pad can be programmed by writing the DRVSTR field in the PIO_CFGRx if the corresponding line is Non-Secure or S_PIO_CFGRx if the I/O line is Secure. For details, refer to the section “Electrical Characteristics”.

Note: When SDHC drives I/O lines, PIO Drive control (PIO_CFGRx) has no effect; only the drive control from SDHC is operational

36.5.14 Programmable Schmitt Trigger

It is possible to configure each input for the Schmitt trigger. The Schmitt trigger can be enabled by setting PIO_CFGRx.SCHMITT if the corresponding line is Non-Secure or S_PIO_CFGRx if the I/O line is Secure. By default, the Schmitt trigger is active.

36.5.15 Programmable Slew Rate

Each output can be configured for slew rate control. Slew rate control can be enabled by setting the bit SR of the PIO_CFGRx if the corresponding line is Non-Secure, or S_PIO_CFGRx if the I/O line is Secure. For details, refer to the section “Electrical Characteristics”.

Slew rate control does not apply to high-speed I/O lines.

36.5.16 I/O Line Configuration Freeze

36.5.16.1 Introduction

The I/O line configuration freeze function can reinforce the protection against the effects of an abnormal access resulting from a Single-event upset that may corrupt the value of one bit on the system bus during an access to the PIO or any other peripheral. Freezing the configuration of an I/O line prevents an unexpected access from modifying the configuration of the I/O line. Once the freeze is done, the I/O line configuration cannot be modified whatever software sequence is performed on the PIO.

36.5.16.2 Software Freeze

Once the I/O line configuration is done, it can be frozen by using the PIO I/O Freeze Configuration Register (PIO_IOFRx) of the corresponding group or the Secure PIO I/O Freeze Configuration Register (S_PIO_IOFRx) if the I/O line is Secure.

36.5.16.2.1 Physical Freeze

Setting PIO_IOFR.FPHY freezes the following fields (configured in PIO_CFGRx) of the Non-Secure I/O lines if the corresponding MSKx bit is set in PIO_MSKRx:

- FUNC: I/O Line Function
- DIR: Direction
- PUEN: Pull-Up Enable
- PDEN: Pull-Down Enable
- OPD: Open-Drain
- SCHMITT: Schmitt Trigger
- DRVSTR: Drive Strength

For Secure I/O lines, use the FPHY bit of the S_PIO_IOFRx and the S_PIO_MSKRx to freeze the fields above.

When the physical freeze is currently active on an I/O line, the PCFS flag is set when reading the PIO_CFGRx of the I/O line if the corresponding line is Non-Secure or the S_PIO_CFGRx if the I/O line is Secure.

Only a hardware reset can release fields listed above.

36.5.16.2.2 Interrupt Freeze

Setting PIO_IOFRx.FINT freezes the following fields (configured in PIO_CFGRx) of the Non-Secure I/O lines if the corresponding MSKx bit is set in PIO_MSKRx:

- IFEN: Input Filter Enable
- IFSCEN: Input Filter Slow Clock Enable
- EVTSEL: Event Selection

For Secure I/O lines, use S_PIO_IOFRx.FINT and the S_PIO_MSKRx to freeze the fields above.

When the “Interrupt Freeze” is currently active on an I/O line, the ICFS flag is set when reading the PIO_CFGRx of the I/O line (or the S_PIO_CFGRx if the I/O line is Secure).

Only a hardware reset can release fields listed above.

36.5.16.3 Tamper Freeze

For safety reasons, each I/O line can be configured to switch automatically in GPIO Input mode with pull-up in case of an external tamper event. This can be done by setting the TAMPEN bit in the PIO_CFGRx (or the S_PIO_CFGRx for a Secure I/O line). If the TAMPEN bit is set, the corresponding I/O line(s) switches automatically in General Purpose IO mode (GPIO) and Pull-Up is activated as long as the tamper event is detected. The “Tamper Freeze” is released when the tamper event is no longer present and frozen I/O line switch back to their applicative configuration automatically.

36.5.17 Register Write Protection

To prevent any single software error from corrupting PIO behavior, certain registers in the address space can be write-protected by setting WPEN and WPITEN in the PIO Write Protection Mode Register (PIO_WPMR) or the Secure PIO Write Protection Mode Register (S_PIO_WPMR).

If a write access to a Non-Secure write-protected register is detected, the WPVS flag in the PIO Write Protection Status Register (PIO_WPSR) is set and the field WPVSRC indicates the register in which the write access has been attempted.

If a write access to a Secure write-protected register is detected, the WPVS flag in the Secure PIO Write Protection Status Register (S_PIO_WPSR) is set and the field WPVSRC indicates the register in which the write access has been attempted.

The respective WPVS bit is automatically cleared after reading the PIO_WPSR or S_PIO_WPSR.

The following registers are write-protected when WPEN is set in PIO_WPMR:

- PIO Mask Register
- PIO Configuration Register

The following registers are write-protected when WPEN is set in S_PIO_WPMR:

- Secure PIO Mask Register
- Secure PIO Configuration Register
- Secure PIO Slow Clock Divider Debouncing Register

The following registers are write-protected when WPITEN is set in PIO_WPMR:

- PIO Interrupt Enable Register
- PIO Interrupt Disable Register

The following registers are write-protected when WPITEN is set in S_PIO_WPMR:

- Secure PIO Interrupt Enable Register
- Secure PIO Interrupt Disable Register

36.6 I/O Lines Programming Example

The programming example shown in the table below is used to obtain the following configurations:

- PIOA Configuration:

- 4-bit output port on Secure I/O lines 0 to 3, open-drain, with pull-up resistor
- Four output signals on Non-Secure I/O lines 4 to 7 (to drive LEDs for example), driven high and low, no pull-up resistor, no pull-down resistor
- Secure I/O lines 16 to 19 assigned to peripheral A functions with pull-up resistor
- Non-Secure I/O lines 20 to 23 assigned to peripheral B functions with pull-down resistor

- PIOB Configuration:
  - Four input signals on Secure I/O lines 0 to 3 (to read push-button states for example), with pull-up resistors, glitch filters and input change interrupts
  - Four input signals on Non-Secure I/O lines 12 to 15 to read an external device status (polled, thus no input change interrupt), no pull-up resistor, no glitch filter
  - Secure I/O lines 16 to 23 assigned to peripheral B functions with pull-down resistor
  - Non-Secure I/O lines 24 to 27 assigned to peripheral D with Input Change Interrupt, no pull-up resistor and no pull-down resistor

Table 36-3. Programming Example

Action	Register	Value to be Written
PIOA: Set I/O lines 0 to 3 and 16 to 19 as Secure	S_PIO_SIOSR0 (offset 0x1034)	0x000F000F
PIOA: Set I/O lines 4 to 7 and 20 to 23 as Non-Secure	S_PIO_SIONR0 (offset 0x1030)	0x00F000F0
PIOA: 4-bit output port on Secure I/O lines 0 to 3, open-drain, with pull-up resistor	S_PIO_MSKR0 (offset 0x1000)	0x0000000F
	S_PIO_CFGR0 (offset 0x1004)	0x00004300
PIOA: Four output signals on Non-Secure I/O lines 4 to 7 (to drive LEDs for example), driven high and low, no pull-up resistor, no pull-down resistor	PIO_MSKR0 (offset 0x0)	0x000000F0
	PIO_CFGR0 (offset 0x4)	0x00000100
PIOA: Secure I/O lines 16 to 19 assigned to peripheral A functions with pull-up resistor	S_PIO_MSKR0 (offset 0x1000)	0x000F0000
	S_PIO_CFGR0 (offset 0x1004)	0x00000201
PIOA: Non-Secure I/O lines 20 to 23 assigned to peripheral B functions with pull-down resistor	PIO_MSKR0 (offset 0x0)	0x00F00000
	PIO_CFGR0 (offset 0x4)	0x00000402
PIOB: Set I/O lines 0 to 3 and 16 to 23as Secure	S_PIO_SIOSR1 (offset 0x1074)	0x00FF000F
PIOB: Set I/O lines 12 to 15 and 24 to 27 as Non-Secure	S_PIO_SIONR1 (offset 0x1070)	0x0F00F000
PIOB: Four input signals on Secure I/O lines 0 to 3 (to read push-button states for example), with pull-up resistors, glitch filters and interrupts on rising edge	S_PIO_MSKR1 (offset 0x1040)	0x0000000F
	S_PIO_CFGR1 (offset 0x1044)	0x01001200

...........continued

Action	Register	Value to be Written
PIOB: Four input signals on Non-Secure I/O line 12 to 15 to read an external device status (polled, thus no input change interrupt), no pull-up resistor, no glitch filter	PIO_MSKR1 (offset 0x40)	0x0000F000
	PIO_CFGR1 (offset 0x44)	0x01001200
PIOB: Secure I/O lines 16 to 23 assigned to peripheral B functions with pull-down resistor	S_PIO_MSKR1 (offset 0x1040)	0x00FF0000
	S_PIO_CFGR1 (offset 0x1044)	0x00000402
PIOB: Non-Secure I/O line 24 to 27 assigned to peripheral D with Input Interrupt on both edges, no pull-up resistor and no pull-down resistor	PIO_MSKR1 (offset 0x40)	0x0F000000
	PIO_CFGR1 (offset 0x44)	0x02000004
PIOB: Enable interrupt	S_PIO_IER1 (offset 0x1060)	0x0000000F
	PIO_IER1 (offset 0x60)	0x0F000000

36.7.1 PIO Mask Register

Name: PIO_MSKRx
Offset: 0x00 + x*0x40 [x=0..4]
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the PIO Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
	MSK31	MSK30	MSK29	MSK28	MSK27	MSK26	MSK25	MSK24

Bits 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31 – MSKy PIO Line y Mask
These bits define the I/O lines to be configured when writing the PIO Configuration Register.
0 (DISABLED): Writing the PIO_CFGRx, PIO_ODSRx or PIO_IOFRx does not affect the corresponding I/O line configuration.
1 (ENABLED): Writing the PIO_CFGRx, PIO_ODSRx or PIO_IOFRx updates the corresponding I/O line configuration.

36.7.2 PIO Configuration Register

Name: PIO_CFGRx
Offset: 0x04 + x*0x40 [x=0..4]
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the PIO Write Protection Mode Register.

Writing this register will only affect I/O lines enabled in the PIO_MSKRx.

Bit	31	30	29	28	27	26	25	24

Bit	7	6	5	4	3	2	1	0
						FUNC[2:0]		
Access						R/W	R/W	R/W
Reset						0	0	0

Bit 31 – TAMPEN Tamper Enable
Defines the action to do in case of tamper event for the I/O lines of the I/O group x defined in the PIO Mask Register.
0 (NO_FREEZE): No effect on the selected I/O lines.
1 (FREEZE): The selected I/O lines are automatically set in GPIO input with pull-up in case of a tamper event detection.

Bit 30 – ICFS Interrupt Configuration Freeze Status (read-only)
Gives information about the freeze state of the following fields of the read I/O line configuration:
• IFEN: Input Filter Enable
• IFSCEN: Input Filter Slow Clock Enable
• EVTSEL: Event Selection
0 (NOT_FROZEN): The fields are not frozen and can be written for this I/O line.
1 (FROZEN): The fields are frozen and cannot be written for this I/O line. Only a hardware reset can release these fields.

Bit 29 – PCFS Physical Configuration Freeze Status (read-only)
Gives information about the freeze state of the following fields of the read I/O line configuration:
• FUNC: I/O Line Function
• DIR: Direction
• PUEN: Pull-Up Enable
• PDEN: Pull-Down Enable
• OPD: Open-Drain
• SCHMITT: Schmitt Trigger
• DRVSTR: Drive Strength
0 (NOT_FROZEN): The fields are not frozen and can be written for this I/O line.
1 (FROZEN): The fields are frozen and cannot be written for this I/O line. Only a hardware reset can release these fields.

Bits 26:24 – EVTSEL[2:0] Event Selection
Defines the type of event to detect on the I/O lines of the I/O group x according to the PIO Mask Register.

Value	Name	Description
0	FALLING	Event detection on input falling edge
1	RISING	Event detection on input rising edge
2	BOTH	Event detection on input both edge
3	LOW	Event detection on low level input
4	HIGH	Event detection on high level input
5	–	Reserved
6	–	Reserved
7	–	Reserved

Bits 17:16 – DRVSTR[1:0] Drive Strength
Defines the drive strength of the I/O lines of the I/O group x according to the PIO Mask Register.

Value	Name	Description
0	LOW_OR_TYPD	Low drive strength when the IO is driven in GPIO mode or by any non high-speed peripheral, else Type D drive for high-speed peripherals. Refer to the section “Electrical Characteristics” for values.
1	HIGH_OR_TYPA	High drive strength when the IO is driven in GPIO mode or by any non high-speed peripheral, else Type A drive for high-speed peripherals. Refer to the section “Electrical Characteristics” for values.
2	LOW_OR_TYPC	Low drive strength when the IO is driven in GPIO mode or by any non high-speed peripheral, else Type C drive for high-speed peripherals. Refer to the section “Electrical Characteristics” for values.
3	LOW_OR_TYPB	Low drive strength when the IO is driven in GPIO mode or by any non high-speed peripheral, else Type B drive for high-speed peripherals. Refer to the section “Electrical Characteristics” for values.

Bit 15 – SCHMITT Schmitt Trigger
Defines the Schmitt trigger configuration of the I/O lines of the I/O group x according to the PIO Mask Register.
0 (ENABLED): Schmitt trigger is enabled for the selected I/O lines.
1 (DISABLED): Schmitt trigger is disabled for the selected I/O lines.

Bit 14 – OPD Open Drain
Defines the open drain configuration of the I/O lines of the I/O group x according to the PIO Mask Register.
0 (DISABLED): The open-drain is disabled for the selected I/O lines. I/O lines are driven at high- and low-level.
1 (ENABLED): The open-drain is enabled for the selected I/O lines. I/O lines are driven at low-level only.

Bit 13 – IFSCEN Input Filter Slow Clock Enable
Defines the clock source of the glitch filtering for the I/O lines of the I/O group x according to the PIO Mask Register.
0 (DISABLED): The glitch filter is able to filter glitches with a duration less than 1 peripheral clock cycle for the selected I/O lines.
1 (ENABLED): The debouncing filter is able to filter pulses with a duration less than 1 divided slow clock cycle for the selected I/O lines.

Bit 12 – IFEN Input Filter Enable
Defines if the glitch filtering is used for the I/O lines of the I/O group x according to the PIO Mask Register.
0 (DISABLED): The input filter is disabled for the selected I/O lines.
1 (ENABLED): The input filter is enabled for the selected I/O lines.

Bit 11 – SR Slew Rate
Slew rate control does not apply to high-speed I/Os.
0 (DISABLED): Slew rate control is disabled for the selected I/O lines.
1 (ENABLED): Slew rate control is enabled for the selected I/O lines.

Bit 10 – PDEN Pull-Down Enable
Defines the pull-down configuration of the I/O lines of the I/O group x according to the PIO Mask Register.
PDEN can be written to 1 only if PUEN is written to 0.
0 (DISABLED): Pull-down is disabled for the selected I/O lines.
1 (ENABLED): Pull-down is enabled for the selected I/O lines only if PUEN is 0.

Bit 9 – PUEN Pull-Up Enable
Defines the pull-up configuration of the I/O lines of the I/O group x according to the PIO Mask Register.
0 (DISABLED): Pull-up is disabled for the selected I/O lines.
1 (ENABLED): Pull-up is enabled for the selected I/O lines.

Bit 8 – DIR Direction
Defines the direction of the I/O lines of the I/O group x according to the PIO Mask Register.
0 (INPUT): The selected I/O lines are pure inputs.
1 (OUTPUT): The selected I/O lines are enabled in output.

Bits 2:0 – FUNC[2:0] I/O Line Function
Defines the function for I/O lines of the I/O group x according to the PIO Mask Register.

Value	Name	Description
0	GPIO	Selects the PIO mode for the selected I/O lines.
1	PERIPH_A	Selects peripheral A for the selected I/O lines.
2	PERIPH_B	Selects peripheral B for the selected I/O lines.
3	PERIPH_C	Selects peripheral C for the selected I/O lines.
4	PERIPH_D	Selects peripheral D for the selected I/O lines.
5	PERIPH_E	Selects peripheral E for the selected I/O lines.
6	PERIPH_F	Selects peripheral F for the selected I/O lines.
7	PERIPH_G	Selects peripheral G for the selected I/O lines.

36.7.3 PIO Pin Data Status Register

Name: PIO_PDSRx
Offset: 0x08 + x*0x40 [x=0..4]
Reset: –
Property: Read-only

Reset value of PIO_PDSR depends on the level of the I/O lines. Reading the I/O line levels requires the clock of the PIO Controller to be enabled, otherwise PIO_PDSR reads the levels present on the I/O line at the time the clock was disabled.

Bits 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31 – Px
Input Change Interrupt Mask

Value	Description
0	Input Change interrupt is disabled on the I/O line of the I/O group x.
1	Input Change interrupt is enabled on the I/O line of the I/O group x.

36.7.11 PIO Interrupt Status Register

Name: PIO_ISRx
Offset: 0x2C + x*0x40 [x=0..4]
Reset: 0x00000000
Property: Read-only

PIO_ISR is reset at 0x00000000. However, the first read of the register may read a different value as input changes may have occurred.

Bit	31	30	29	28	27	26	25	24

Input Change Interrupt Status

Value	Description
0	No Input Change has been detected on the I/O line of the I/O group x since PIO_ISRx was last read or since reset.
1	At least one Input Change has been detected on the I/O line of the I/O group since PIO_ISRx was last read or since reset.

36.7.12 PIO I/O Freeze Configuration Register

Name: PIO_IOFRx
Offset: 0x3C + x*0x40 [x=0..4]
Reset: –
Property: Write-only

Writing this register will only affect I/O lines enabled in the PIO_MSKRx.

Bit	31	30	29	28	27	26	25	24
	FRZKEY[23:16]							
Access	W	W	W	W	W	W	W	W

Reset	–	–	–	–	–	–	–	–

Bit	7	6	5	4	3	2	1	0
							FINT	FPHY
Access							W	W
Reset							–	–

Bits 31:8 – FRZKEY[23:0] Freeze Key

Value	Name	Description
0x494F46	PASSWD	Writing any other value in this field aborts the write operation of the WPEN bit.

Bit 1 – FINT Freeze Interrupt Configuration
Only a hardware reset can reset the FINT bit.

Value	Description
0	No effect.
1	Freezes the following configuration fields of Non-Secure I/O lines if FRZKEY corresponds to 0x494F46 (“IOF” in ASCII): • IFEN: Input Filter Enable • IFSCEN: Input Filter Slow Clock Enable • EVTSEL: Event Selection

Bit 0 – FPHY Freeze Physical Configuration
Only a hardware reset can reset the FPHY bit.

Value	Description
0	No effect.

Value	Description
1	Freezes the following configuration fields of Non-Secure I/O lines if FRZKEY corresponds to 0x494F46 (“IOF” in ASCII): • FUNC: I/O Line Function • DIR: Direction • PUEN: Pull-Up Enable • PDEN: Pull-Down Enable • OPD: Open-Drain • SCHMITT: Schmitt Trigger • DRVSTR: Drive Strength

36.7.13 PIO Tamper Freeze Register

Name: PIO_TPFR
Offset: 0x5D0
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
	FRZKEY[23:16]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
								TAMPFRZ
Access								R/W
Reset								0

Bits 31:8 – FRZKEY[23:0] Freeze Key

Value	Name	Description
0x545046	PASSWD	Writing any other value in this field aborts the write operation of the TAMPFRZ bit.

Bit 0 – TAMPFRZ Freeze on Tamper Event
On tamper detection, Non-Secure I/O lines with TAMPEN bit at 1 will be forced as GPIO inputs with pull-up.
Only a hardware reset can reset the TAMPFRZ bit.

Value	Description
0	No effect.
1	Enables freeze of Non-Secure I/O lines on tamper event detection if FRZKEY corresponds to 0x545046 (“TPF” in ASCII).

36.7.14 PIO Write Protection Mode Register

Name: PIO_WPMR
Offset: 0x5E0
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
	WPKEY[23:16]							
Access	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0

	WPKEY[7:0]							
Access	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
							WPITEN	WPEN
Access							R/W	R/W
Reset							0	0

Bits 31:8 – WPKEY[23:0] Write Protection Key

Value	Name	Description
0x50494F	PASSWD	Writing any other value in this field aborts the write operation of the WPEN bit. Always reads as 0.

Bit 1 – WPITEN Write Protection Interrupt Enable
See Register Write Protection for the list of registers that can be protected.

Value	Description
0	Disables the write protection on interrupt registers if WPKEY corresponds to 0x50494F (“PIO” in ASCII).
1	Enables the write protection on interrupt registers if WPKEY corresponds to 0x50494F (“PIO” in ASCII).

Bit 0 – WPEN Write Protection Enable
See Register Write Protection for the list of registers that can be protected.

Value	Description
0	Disables the write protection if WPKEY corresponds to 0x50494F (“PIO” in ASCII).
1	Enables the write protection if WPKEY corresponds to 0x50494F (“PIO” in ASCII).

36.7.15 PIO Write Protection Status Register

Name: PIO_WPSR
Offset: 0x5E4
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								
Bit	23	22	21	20	19	18	17	16
	WPVSRC[15:8]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
								WPVS
Access								R
Reset								0

Bits 23:8 – WPVSRC[15:0] Write Protection Violation Source
When WPVS = 1, WPVSRC indicates the register address offset at which a write access has been attempted.

Bit 0 – WPVS Write Protection Violation Status

Value	Description
0	No write protection violation has occurred since the last read of the PIO_WPSR.
1	A write protection violation has occurred since the last read of the PIO_WPSR. If this violation is an unauthorized attempt to write a protected register, the associated violation is reported into field WPVSRC.

36.7.16 Secure PIO Mask Register

Name: S_PIO_MSKRx
Offset: 0x1000 + x*0x40 [x=0..4]
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the Secure PIO Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
	MSK31	MSK30	MSK29	MSK28	MSK27	MSK26	MSK25	MSK24

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31 – MSKy PIO Line y Mask
These bits define the I/O lines to be configured when writing the Secure PIO Configuration Register.
0 (DISABLED): Writing the S_PIO_CFGRx, S_PIO_ODSRx or S_PIO_IOFRx does not affect the corresponding I/O line configuration.
1 (ENABLED): Writing the S_PIO_CFGRx, S_PIO_ODSRx or S_PIO_IOFRX updates the corresponding I/O line configuration.

36.7.17 Secure PIO Configuration Register

Name: S_PIO_CFGRx
Offset: 0x1004 + x*0x40 [x=0..4]
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the Secure PIO Write Protection Mode Register.

Writing this register will only affect I/O lines enabled in the S_PIO_MSKRx.

Bit	31	30	29	28	27	26	25	24
	TAMPEN	ICFS	PCFS			EVTSEL[2:0]		
Access	R/W	R	R			R/W	R/W	R/W

Bit	23	22	21	20	19	18	17	16
							DRVSTR[1:0]	
Access							R/W	R/W
Reset							0	0

Bit	15	14	13	12	11	10	9	8
	SCHMITT	OPD	IFSCEN	IFEN		PDEN	PUEN	DIR
Access	R/W	R/W	R/W	R/W		R/W	R/W	R/W
Reset	0	0	0	0		0	0	0

Bit	7	6	5	4	3	2	1	0
						FUNC[2:0]		
Access						R/W	R/W	R/W
Reset						0	0	0

Bit 31 – TAMPEN Tamper Enable
Defines the action to do in case of tamper event for the I/O lines of the I/O group x defined in the Secure PIO Mask Register.
0 (NO_FREEZE): No effect on the selected I/O lines.
1 (FREEZE): The selected I/O lines are automatically set in GPIO input with pull-up in case of a tamper event detection.

Bit 30 – ICFS Interrupt Configuration Freeze Status
Gives information about the freeze state of the following fields of the read I/O line configuration:
• IFEN: Input Filter Enable
• IFSCEN: Input Filter Slow Clock Enable
• EVTSEL: Event Selection
0 (NOT_FROZEN): The fields are not frozen and can be written for this I/O line.
1 (FROZEN): The fields are frozen and cannot be written for this I/O line. Only a hardware reset can release these fields.

Bit 29 – PCFS Physical Configuration Freeze Status
Gives information about the freeze state of the following fields of the read I/O line configuration:
• FUNC: I/O Line Function
• DIR: Direction
• PUEN: Pull-Up Enable
• PDEN: Pull-Down Enable
• OPD: Open-Drain
• SCHMITT: Schmitt Trigger
• DRVSTR: Drive Strength
0 (NOT_FROZEN): The fields are not frozen and can be written for this I/O line.

1 (FROZEN): The fields are frozen and cannot be written for this I/O line. Only a hardware reset can release these fields.

Bits 26:24 – EVTSEL[2:0] Event Selection
Defines the type of event to detect on the I/O lines of the I/O group x according to the Secure PIO Mask Register.

Value	Name	Description
0	FALLING	Event detection on input falling edge
1	RISING	Event detection on input rising edge
2	BOTH	Event detection on input both edge
3	LOW	Event detection on low level input
4	HIGH	Event detection on high level input
5	–	Reserved
6	–	Reserved
7	–	Reserved

Bits 17:16 – DRVSTR[1:0] Drive Strength
Defines the drive strength of the I/O lines of the I/O group x according to the PIO Mask Register.

Value	Name	Description
0	LOW_OR_HS100	Low drive strength when the IO is driven in GPIO mode or by any non high-speed peripheral, else lowest drive for high-speed peripherals. Refer to the section “Electrical Characteristics” for values.
1	HIGH_OR_HS33	High drive strength when the IO is driven in GPIO mode or by any non high-speed peripheral, else highest drive for high-speed peripherals. Refer to the section “Electrical Characteristics” for values.
2	LOW_OR_HS66	Low drive strength when the IO is driven in GPIO mode or by any non high-speed peripheral, else middle-low drive for high-speed peripherals. Refer to the section “Electrical Characteristics” for values.
3	LOW_OR_HS50	Low drive strength when the IO is driven in GPIO mode or by any non high-speed peripheral, else middle-high drive for high-speed peripherals. Refer to the section “Electrical Characteristics” for values.

Bit 15 – SCHMITT Schmitt Trigger
Defines the Schmitt trigger configuration of the I/O lines of the I/O group x according to the Secure PIO Mask Register.
0 (ENABLED): Schmitt trigger is enabled for the selected I/O lines.
1 (DISABLED): Schmitt trigger is disabled for the selected I/O lines.

Bit 14 – OPD Open Drain
Defines the open drain configuration of the I/O lines of the I/O group x according to the Secure PIO Mask Register.
0 (DISABLED): The open drain is disabled for the selected I/O lines. I/O lines are driven at high- and low-level.
1 (ENABLED): The open drain is enabled for the selected I/O lines. I/O lines are driven at low-level only.

Bit 13 – IFSCEN Input Filter Slow Clock Enable
Defines the clock source of the glitch filtering for the I/O lines of the I/O group x according to the Secure PIO Mask Register.

Value	Description
0	The glitch filter is able to filter glitches with a duration less than 1 peripheral clock cycle for the selected I/O lines.
1	The debouncing filter is able to filter pulses with a duration less than 1 divided slow clock cycle for the selected I/O lines.

Bit 12 – IFEN Input Filter Enable
Defines if the glitch filtering is used for the I/O lines of the I/O group x according to the Secure PIO Mask Register.
0 (DISABLED): The input filter is disabled for the selected I/O lines.
1 (ENABLED): The input filter is enabled for the selected I/O lines.

Bit 10 – PDEN Pull-Down Enable
Defines the pull-down configuration of the I/O lines of the I/O group x according to the Secure PIO Mask Register.
PDEN can be written to 1 only if PUEN is written to 0.
0 (DISABLED): Pull-down is disabled for the selected I/O lines.
1 (ENABLED): Pull-down is enabled for the selected I/O lines only if PUEN is 0.

Bit 9 – PUEN Pull-Up Enable
Defines the pull-up configuration of the I/O lines of the I/O group x according to the Secure PIO Mask Register.
0 (DISABLED): Pull-up is disabled for the selected I/O lines.
1 (ENABLED): Pull-up is enabled for the selected I/O lines.

Bit 8 – DIR Direction
Defines the direction of the I/O lines of the I/O group x according to the Secure PIO Mask Register.
0 (INPUT): The selected I/O lines are pure inputs.
1 (OUTPUT): The selected I/O lines are enabled in output.

Bits 2:0 – FUNC[2:0] I/O Line Function
Defines the function for I/O lines of the I/O group x according to the Secure PIO Mask Register.

Value	Name	Description
0	GPIO	Selects the PIO mode for the selected I/O lines.
1	PERIPH_A	Selects peripheral A for the selected I/O lines.
2	PERIPH_B	Selects peripheral B for the selected I/O lines.
3	PERIPH_C	Selects peripheral C for the selected I/O lines.
4	PERIPH_D	Selects peripheral D for the selected I/O lines.
5	PERIPH_E	Selects peripheral E for the selected I/O lines.
6	PERIPH_F	Selects peripheral F for the selected I/O lines.
7	PERIPH_G	Selects peripheral G for the selected I/O lines.

36.7.18 Secure PIO Pin Data Status Register

Name: S_PIO_PDSRx
Offset: 0x1008 + x*0x40 [x=0..4]
Reset: –
Property: Read-only

Reset value of PIO_PDSR and S_PIO_PDSR depends on the level of the I/O lines. Reading the I/O line levels requires the clock of the PIO Controller to be enabled, otherwise PIO_PDSR reads the levels present on the I/O line at the time the clock was disabled.

Reset	–	–	–	–	–	–	–	–

Bits 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31 – Px
Clear Output Data

Value	Description
0	No effect.
1	Clears the data to be driven on the I/O line of the I/O group x.

36.7.22 Secure PIO Output Data Status Register

Name: S_PIO_ODSRx
Offset: 0x1018 + x*0x40 [x=0..4]
Reset: 0x00000000
Property: Read/Write

Writing this register will only affect I/O lines enabled in the S_PIO_MSKRx.

Input Change Interrupt Mask

Value	Description
0	Input Change interrupt is disabled on the I/O line of the I/O group x.
1	Input Change interrupt is enabled on the I/O line of the I/O group x.

36.7.26 Secure PIO Interrupt Status Register

Name: S_PIO_ISRx
Offset: 0x102C + x*0x40 [x=0..4]
Reset: 0x00000000
Property: Read-only

PIO_ISR and S_PIO_ISR are reset at 0x000000000. However, the first read of the register may read a different value as input changes may have occurred.

Reset								0

Bits 23:8 – WPVSRC[15:0] Write Protection Violation Source
When WPVS = 1, WPVSRC indicates the register address offset at which a write access has been attempted.

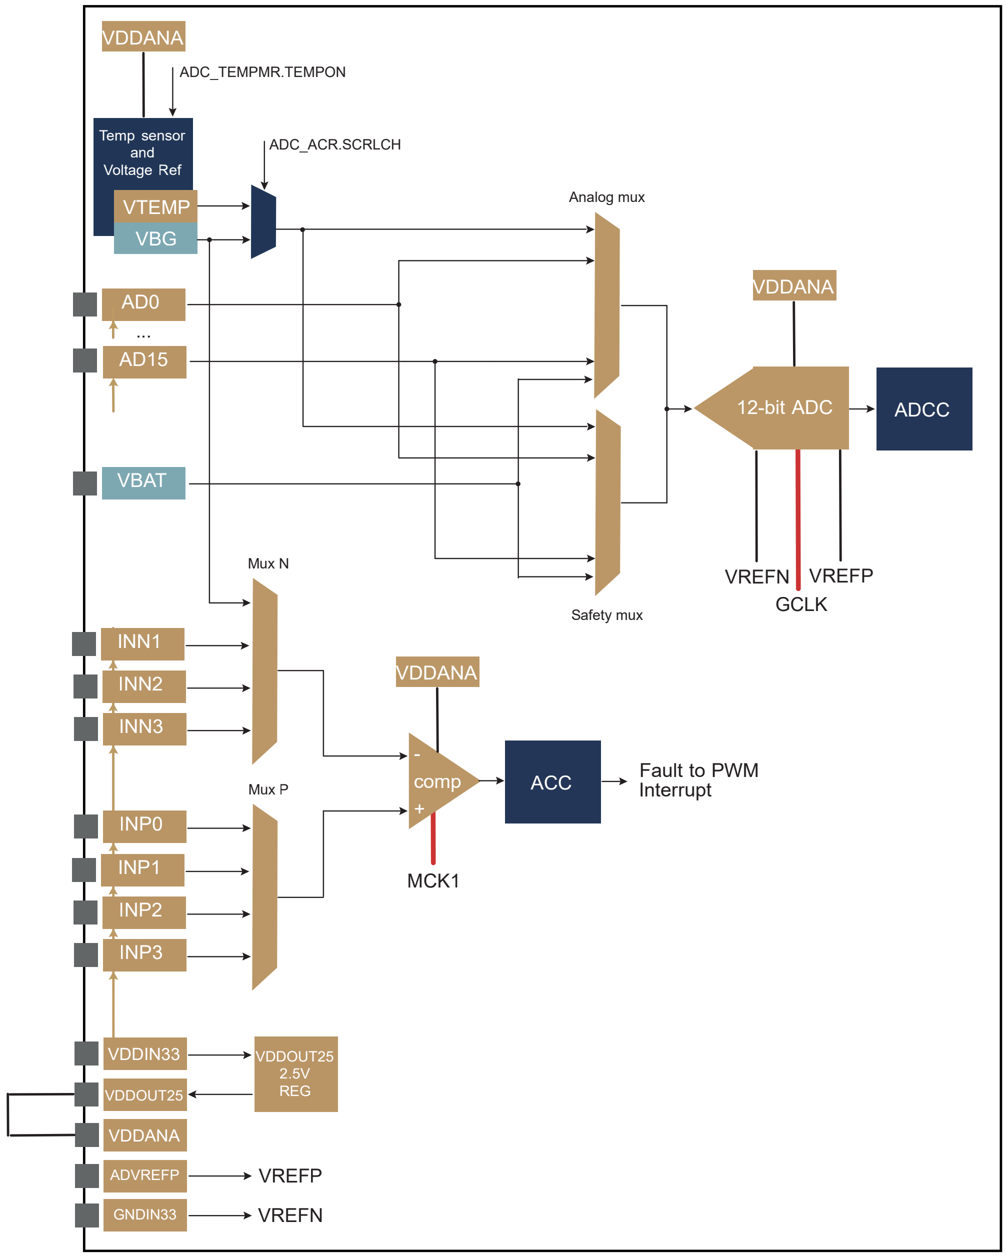
Bit 0 – WPVS Write Protection Violation Status

Value	Description
0	No write protection violation has occurred since the last read of the S_PIO_WPSR.
1	A write protection violation has occurred since the last read of the S_PIO_WPSR. If this violation is an unauthorized attempt to write a protected register, the associated violation is reported into field WPVSRC.

37. ANALOG SUBSYSTEM

37.1 Block Diagram

Figure 37-1. Analog Subsystem Block Diagram



Before using VTEMP or VBG as ADC or ACC input, enable the temperature sensor and voltage reference with ADC_TEMPMR.TEMPON =1.

37.2 Components

- Analog-to-Digital Converter (ADC)

- Temperature sensor and reference block
- Analog Comparator (ACC)

37.3 Product Dependencies

37.3.1 Clocks

All clocks are controlled by the PMC, which is a part of the system controller.

ADC is only clocked by its GCLK. It must be started before any operation.

ACC is located on the APB Client (APS) matrix, clocked by MCK1.

37.3.2 Interrupts

Refer to the table Peripheral Identifiers.

37.3.3 Reset

Analog peripherals are connected to the processor and peripherals reset line.

37.3.4 I/Os

Analog I/Os are seven ACC inputs and 16 ADC inputs powered by VDDIN33/GNDIN33. To avoid any unwanted input loading, disable the pull-up and pull-down resistors before using these lines in the PIO_CFGRx and S_PIO_CFGRx registers.

37.4 Special Functions in SFR/SFRBU

None.

38. Analog-to-Digital Converter (ADC) Controller

38.1 Description

The ADC is based on a 12-bit Analog-to-Digital Converter (ADC) managed by an ADC Controller providing enhanced resolution up to 16 bits. The conversions extend from the voltage carried on pin GNDIN33 to the voltage carried on pin ADVREFP.

Conversion results are reported in a common register for all channels, as well as in a channel-dedicated register.

The 13-bit, 14-bit, 15-bit and 16-bit resolution modes are obtained by averaging multiple samples to decrease quantization noise. For the 13-bit mode, 4 samples are used, which gives a real sample rate of 1/4 of the actual sample frequency. For the 14-bit mode, 16 samples are used, giving a real sample rate of 1/16 of the actual sample frequency. For the 15-bit and 16-bit modes, respectively 64 and 256 samples are used, giving a real sample rate of respectively 1/64 and 1/256 of the actual sample frequency. This arrangement allows conversion speed to be traded off against for better accuracy.

The last channel is internally connected to the temperature sensor output voltage (VTEMP) or to the reference voltage (VBG). The selection is controlled in the analog control register (ADC_ACR).

The software trigger, external trigger on rising edge of the ADTRG pin or internal triggers from Timer Counter output(s) can be selected for triggering a conversion.

The comparison circuitry allows automatic detection of values below a threshold, higher than a threshold, in a given range or outside the range, thresholds and ranges being fully configurable.

The ADC Controller internal fault output is directly connected to the PWM fault input. This input can be asserted by means of a comparison circuitry to immediately put the PWM output in a safe state (pure combinational path).

The ADC also integrates a Sleep mode and a conversion sequencer and connects with a DMA channel. These features reduce both power consumption and processor intervention.

This ADC has a selectable single-ended or fully differential input.

Note: In this section, REFP = ADVREFP and REFN = GNDIN33.

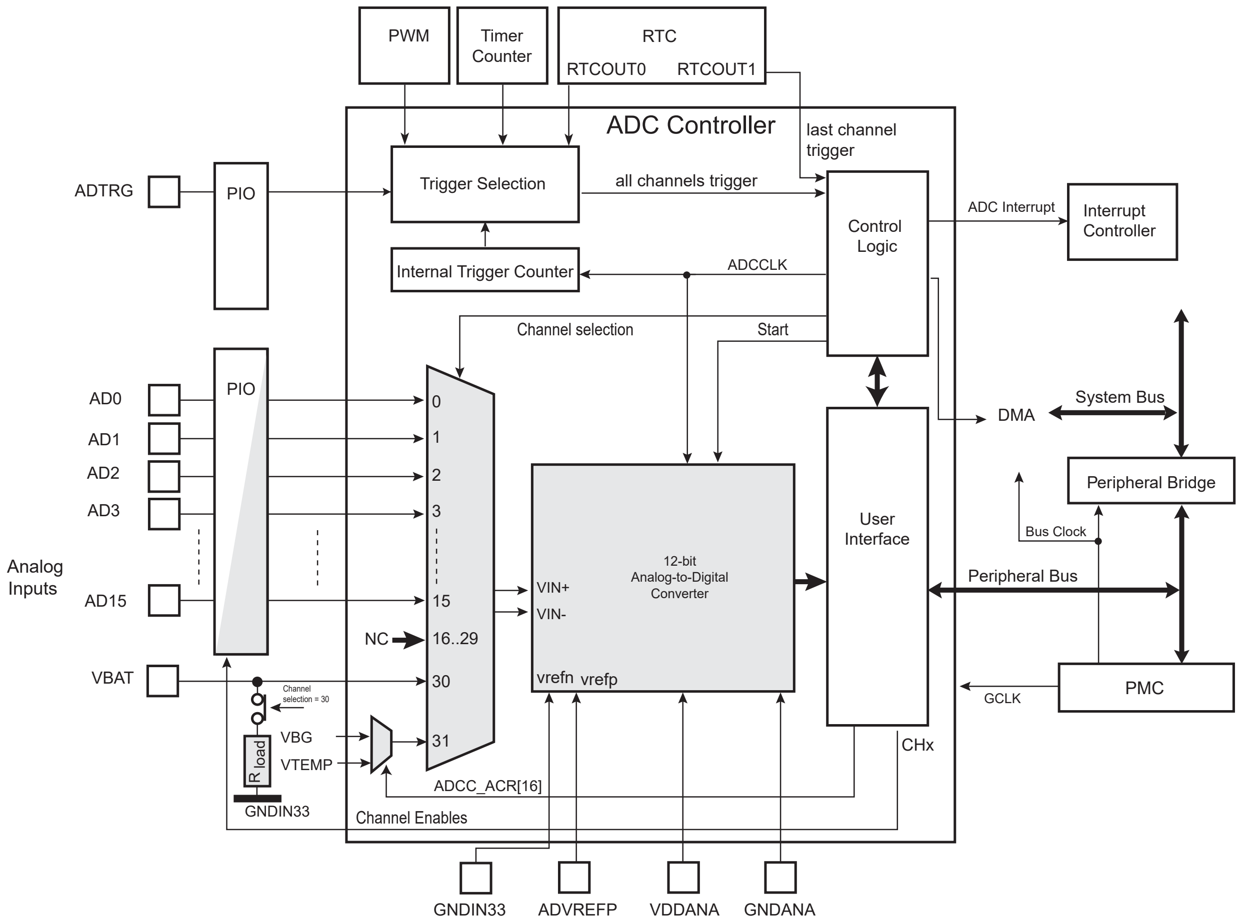
38.2 Embedded Characteristics

- 12-bit Resolution with Enhanced Mode up to 16 bits
- 1 MSps Conversion Rate
- Digital Averaging Function providing Enhanced Resolution Mode up to 16 bits
- On-chip Temperature Sensor Management
- Selectable Single-Ended or Differential Input Voltage
- Digital Correction of Offset and Gain Errors
- Individual Enable and Disable of Each Channel
- Hardware or Software Trigger from:
  - External trigger pin
  - ADC internal trigger counter
  - Timer Counter outputs
  - PWM event line
- Drive of PWM Fault Input
- DMA Support
- Two Sleep Modes (Automatic Wake-up on Trigger)
  - Lowest power consumption (voltage reference OFF between conversions)
  - Fast wake-up time response on trigger event (voltage reference ON between conversions)
- Channel Sequence Customizing

- Automatic Window Comparison of Converted Values
- Register Write Protection

38.3 Block Diagram

Figure 38-1. ADC Block Diagram



38.4 Product Dependencies

38.4.1 Power Management

The ADC Controller is not continuously clocked. The programmer must first enable the ADC Controller peripheral clock in the Power Management Controller (PMC) before using the ADC Controller. However, if the application does not require ADC operations, the ADC Controller clock can be stopped when not needed and restarted when necessary. Configuring the ADC Controller does not require the ADC Controller clock to be enabled.

38.4.2 Interrupt Sources

The ADC interrupt line is connected on one of the internal sources of the Interrupt Controller. Using the ADC interrupt requires the interrupt controller to be programmed first.

38.4.3 Battery Voltage

The battery voltage is internally connected to the channel with the highest index minus one. A fixed division factor is applied on VBAT voltage to fit the CH30 maximum input range (refer to the section “Electrical Characteristics” for the ratio value).

38.4.4 Temperature Sensor

The temperature sensor is internally connected to the channel with the highest index of the ADC.

The temperature sensor provides two output voltages VTEMP and VBG. VTEMP is proportional to the absolute temperature (PTAT) voltage and VBG is a quasi-temperature independent voltage.

To activate the temperature sensor, the bit TEMPON in the Temperature Sensor Mode register (ADC_TEMPMR) must be set. After setting the bit, the start-up time of the temperature sensor must be achieved prior to initiating any measurements.

38.4.5 I/O Lines

The digital inputs ADx and ADTRG are multiplexed with digital functions on the I/O lines. The analog mode for ADx I/O pins is automatically selected when the corresponding conversion channel is enabled. ADTRG is enabled by configuring the PIO controller.

38.4.6 Hardware Triggers

The ADC can use internal signals to start conversions. See the field TRGSEL for details on the wiring of internal triggers.

38.4.7 Fault Output

The ADC Controller has the FAULT output connected to the FAULT input of PWM. Refer to sections Fault Event and “Pulse Width Modulation Controller (PWM)”.

38.5 Functional Description

38.5.1 Analog-to-Digital Conversion

Once the programmed start-up time (ADC_MR.STARTUP) has elapsed, ADC conversions are sequenced by three operating times:

- Tracking time—the time for the ADC to charge its input sampling capacitor to the input voltage. When several channels are converted consecutively, the inherent tracking time is 6 ADC clock cycles. However, the tracking time can be increased using ADC_MR.TRACKTIM and the TRACKX field in the Extended Mode register (ADC_EMR).
- ADC inherent conversion time—the time for the ADC to convert the sampled analog voltage. This time is constant and is defined from start of conversion to end of conversion.
- Channel conversion period—the effective time between the end of the current channel conversion and the end of the next channel conversion.

Figure 38-2. Sequence of Consecutive ADC Conversions with TRACKTIM = 0

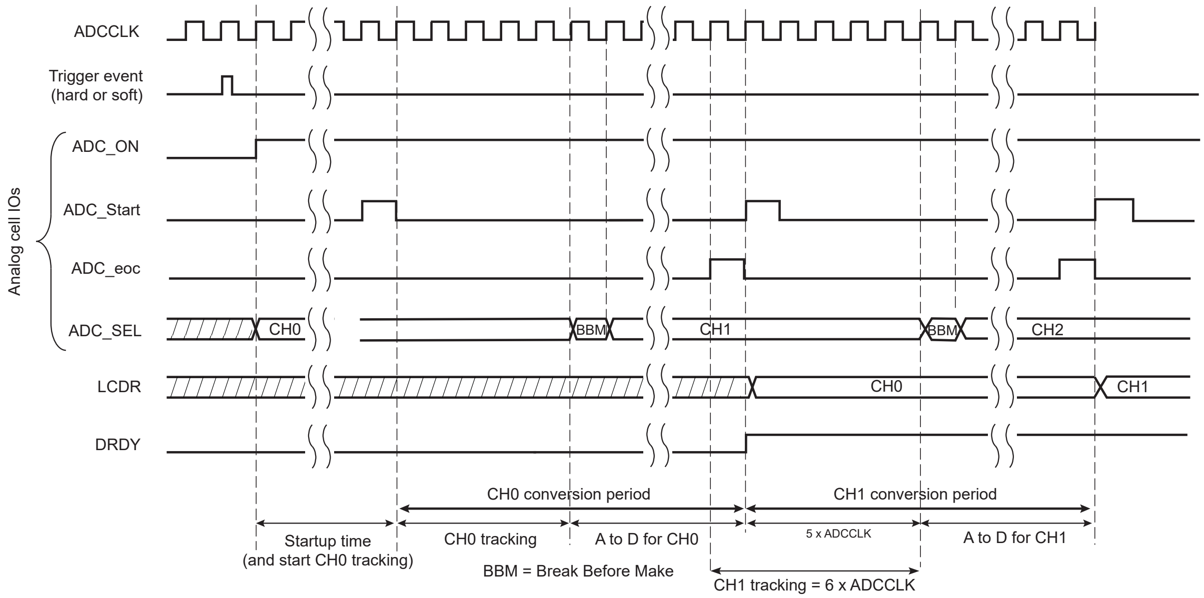


Figure 38-3. Sequence of Consecutive ADC Conversions with TRACKTIM = 4 and TRACKX = 1

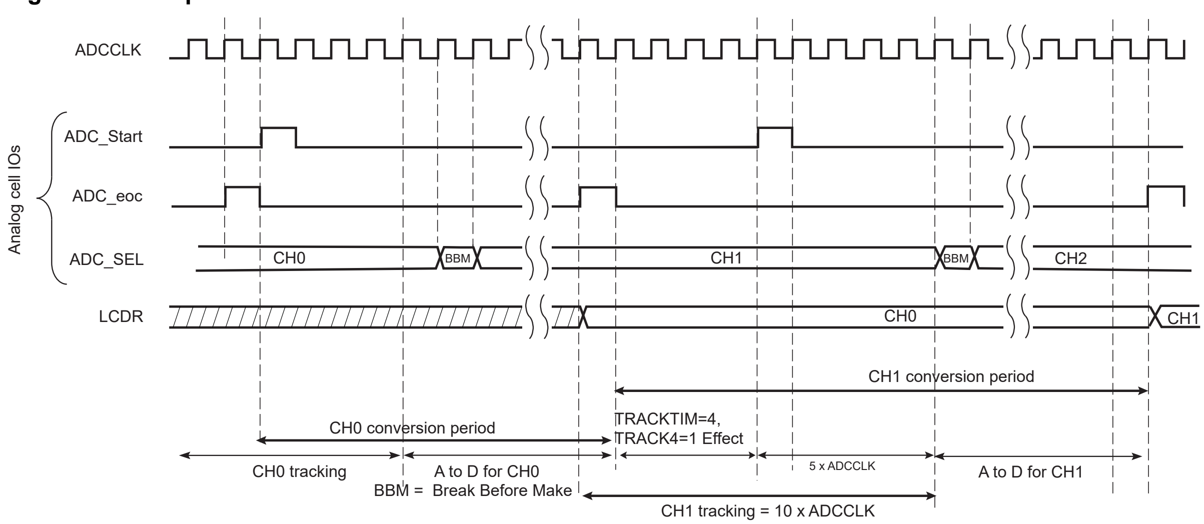


38.5.2 ADC Clock

The ADC uses the ADC clock (ADCCLK) to perform conversions. The ADC clock frequency is selected in ADC_MR.PRESCAL.

To generate the ADC clock, the prescaler uses the peripheral clock driven by a GCLK clock.

ADC_MR.PRESCAL must be programmed to provide the ADC clock frequency parameter given in the section “Electrical Characteristics”.

38.5.3 ADC Reference Voltage

The voltage reference input of the ADC is the ADVREFP pin. Refer to the section “Electrical Characteristics” for further details.

38.5.4 Conversion Resolution

The ADC has a native resolution of 12 bits.

The ADC Controller provides enhanced resolution up to 16 bits by means of digital averaging.

If the digital input ADTRG is asynchronous to the ADC peripheral clock, the internal resynchronization introduces a jitter of 1 peripheral clock. This jitter may reduce the resolution of the converted signal.

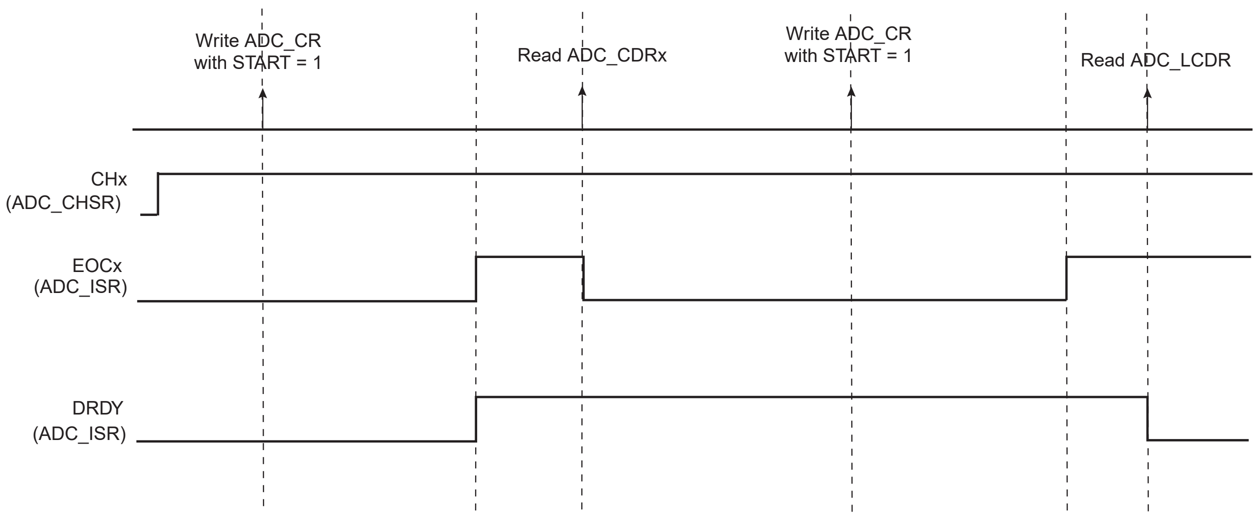
38.5.5 Conversion Results

When a conversion is completed, the resulting digital value is stored in the Channel Data register (ADC_CDRx) of the current channel and in the Last Converted Data register (ADC_LCDR). By setting ADC_EMR.TAG, ADC_LCDR presents the channel number associated with the last converted data in NO_OSR_CHNB/CHNBOSR.

When a conversion is completed, EOCx in the End of Conversion Interrupt Status register (ADC_EOC_ISR) and the bit DRDY in the Interrupt Status register (ADC_ISR) are set. In the case of a connected DMA channel, DRDY rising triggers a data request. In any case, either EOC or DRDY can trigger an interrupt.

Reading one of the ADC_CDRx clears the corresponding EOC. Reading ADC_LCDR clears DRDY.

Figure 38-4. EOCx and DRDY Flag Behavior

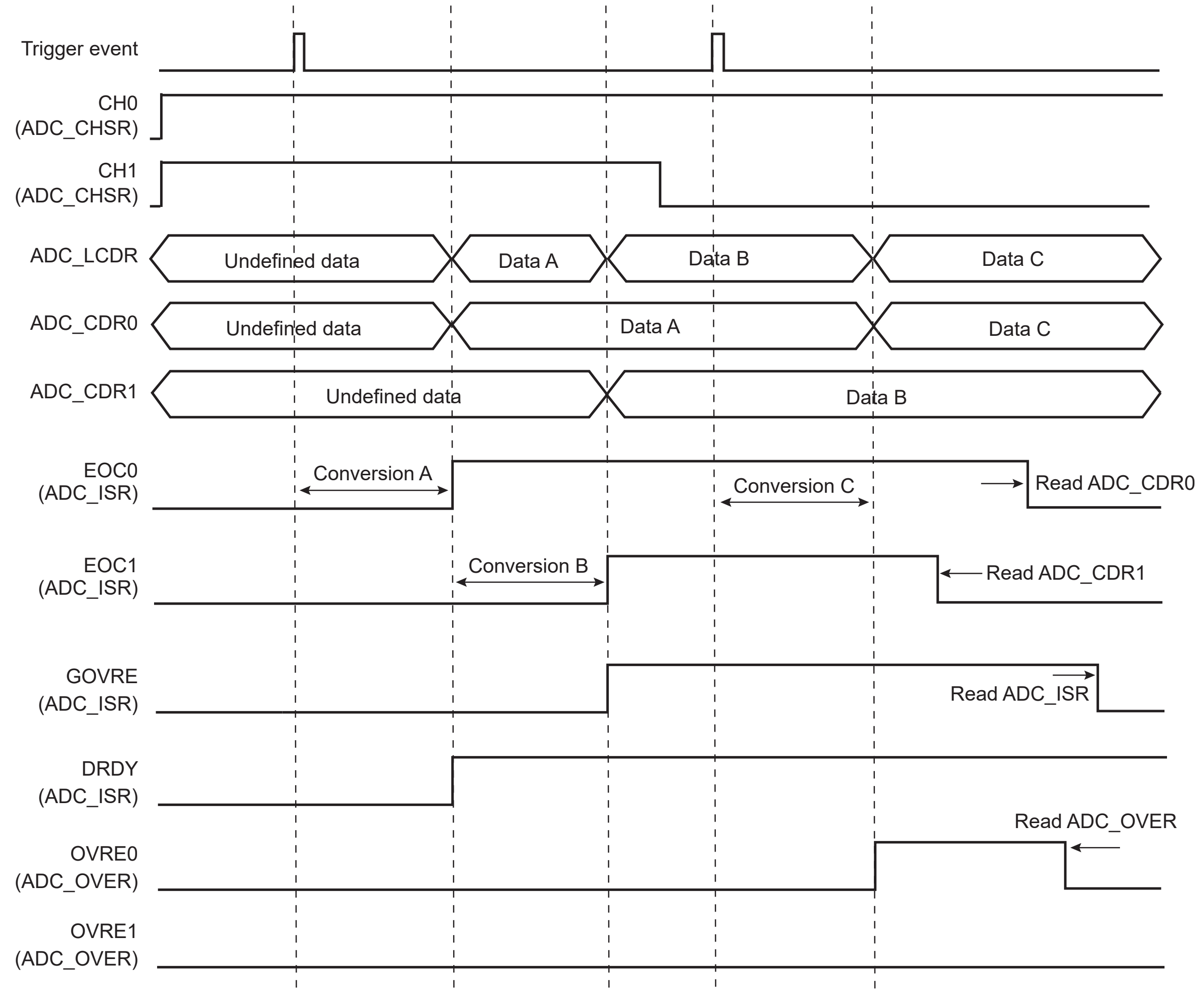


If ADC_CDRx is not read before further incoming data is converted, the corresponding OVREx flag is set in the Overrun Status register (ADC_OVER).

If new data is converted when DRDY is high, ADC_ISR.GOVRE is set.

The OVREx flag is automatically cleared when ADC_OVER is read, and the GOVRE flag is automatically cleared when ADC_ISR is read.

Figure 38-5. EOCx, OVREx and GOVRE Flag Behavior



WARNING If the corresponding channel is disabled during a conversion or if it is disabled and then re-enabled during a conversion, its associated data and corresponding ADC_EOC_ISR.EOCx, ADC_ISR.GOVRE and ADC_OVER.OVREx flags are unpredictable.

38.5.6 Conversion Results Format

The conversion results can be signed (2's complement) or unsigned, depending on the value of ADC_EMR.SIGNMODE.

If conversion results are signed and resolution is less than 16 bits, the sign is extended up to bit 15 (e.g., 0xF43 for 12-bit resolution is read as 0xFF43, and 0x467 is read as 0x0467).

38.5.7 Conversion Triggers

Conversions of the active analog channels are started with a software or hardware trigger. The software trigger is provided by writing the Control register (ADC_CR) with ADC_CR.START at 1.

The list of external/internal events is provided in ADC_MR. The hardware trigger is selected using ADC_MR.TRGSEL. The selected hardware trigger is enabled if TRGMOD = 1, 2 or 3 in the Trigger register (ADC_TRGR).

The ADC also provides a dual trigger mode (ADC_TEMPMR.TEMPON=1) in which the highest index channel can be sampled at a rhythm different from the other channels. The trigger of the last channel is generated by the RTC. See Temperature Sensor.

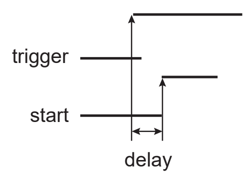
ADC_TRGR.TRGMOD selects the hardware trigger from the following:

- any edge, either rising or falling or both, detected on the external trigger pin ADTRG or internal triggers (provided by other peripherals)
- a continuous trigger, meaning the ADC Controller restarts the next sequence as soon as it finishes the current one
- a periodic trigger (generated by the ADC Controller), which is defined by programming ADC_TRGR.TRGPER

The minimum time between two consecutive trigger events must be strictly greater than the duration time of the longest conversion sequence according to configuration of registers ADC_MR, ADC_SEQRx (Channel Sequence register), ADC_CHSR (Channel Status register).

If a hardware trigger is selected, the start of a conversion is triggered after a delay starting at each rising edge of the selected signal. Due to asynchronous handling, the delay may vary in a range of two peripheral clock periods to one ADC clock period. This delay introduces sampling jitter in the A/D conversion process and may therefore degrade the conversion performance (e.g., SNR, THD).

Figure 38-6. Hardware Trigger Delay



Only one start command is necessary to initiate a conversion sequence on all the enabled channels. The ADC hardware logic automatically performs the conversions on the active channels, then waits for a new request. The Channel Enable (ADC_CHER) and Channel Disable (ADC_CHDR) registers enable the analog channels to be enabled or disabled independently.

If the ADC is used with a DMA channel, only the transfers of converted data from enabled channels are performed and the resulting data buffers should be interpreted accordingly.

38.5.8 Sleep Mode and Conversion Sequencer

The ADC Sleep mode maximizes power saving by automatically deactivating the ADC when it is not being used for conversions. Sleep mode is selected by setting ADC_MR.SLEEP.

Sleep mode is managed by a conversion sequencer, which automatically processes the conversions of all channels at the lowest power consumption.

This mode can be used when the minimum period of time between two successive trigger events is greater than the start-up period of the ADC. Refer to the section “Electrical Characteristics”.

When a start conversion request occurs, the ADC is automatically activated. As the analog cell requires a start-up time, the logic waits during this time and starts the conversion on the enabled channels. When all conversions are complete, the ADC is deactivated until the next trigger. Events triggered during the sequence are ignored.

The conversion sequencer allows automatic processing with minimum processor intervention and optimized power consumption. Conversion sequences can be performed periodically using the internal timer (ADC_TRGR) or the PWM event line. The periodic acquisition of several samples can be processed automatically without any intervention of the processor via the DMA channel.

The sequence can be customized by programming ADC_SEQR1 and ADC_SEQR2 and setting ADC_MR.USEQ. This sequence is limited to 16 channels, from 0 to 15. The user can choose a specific order of channels and can program up to 16 conversions by sequence. The user is free to create a personal sequence by writing channel numbers in ADC_SEQR1 and ADC_SEQR2. Not only can channel numbers be written in any sequence, channel numbers can be repeated several times. When ADC_MR.USEQ is set, ADC_SEQR1.USCHx and ADC_SEQR2.USCHx are used to define the sequence. Only enabled USCHx fields will be part of the sequence. Each USCHx field has a corresponding enable, CHx-1, in ADC_CHER.

If 16 channels are used on an application board, there is no restriction of usage of the user sequence. However, if some ADC channels are not enabled for conversion but rather used as pure digital inputs, the respective indexes of these channels cannot be used in the user sequence fields (see ADC_SEQR1 and ADC_SEQR2). For example, if channel 4 is disabled (ADC_CHSR[4] = 0), ADC_SEQRx fields USCH1 up to USCH16 must not contain the value 4. Thus the length of the user sequence may be limited by this behavior.

As an example, if only four channels (CH0 up to CH3) are selected for ADC conversions, the user sequence length cannot exceed four channels. Each trigger event may launch up to four successive conversions of any combination of channels 0 up to 3, but no more (i.e., in this case the sequence CH0, CH0, CH1, CH1, CH1 is impossible).

A sequence that repeats the same channel several times requires more enabled channels than channels actually used for conversion. For example, the sequence CH0, CH0, CH1, CH1 requires four enabled channels (four free channels on application boards) whereas only CH0, CH1 are really converted.

Note: The reference voltage pins always remain connected in Normal mode as in Sleep mode.

38.5.9 Comparison Window

The ADC Controller features automatic comparison functions. It compares converted values to a low threshold, a high threshold or both, depending on the value of ADC_EMR.CMPMODE. The comparison can be done on all channels or only on the channel specified in ADC_EMR.CMPSEL. To compare all channels, ADC_EMR.CMPALL must be set.

If set, ADC_EMR.CMPTYPE can be used to discard all conversion results that do not match the comparison conditions. Once a conversion result matches the comparison conditions, all the subsequent conversion results are stored in ADC_LCDR (even if these results do not meet the comparison conditions). Setting ADC_CR.CMPRST immediately stops the conversion result storage until the next comparison match.

If ADC_EMR.CMPTYPE is cleared, all conversions are stored in ADC_LCDR. Only the conversions that match the comparison conditions trigger the ADC_ISR.COMPE flag.

Moreover, a filtering option can be set by writing the number of consecutive comparison matches needed to raise the flag. This number can be written and read in ADC_EMR.CMPFILTER. The filtering option is dedicated to reinforcing the detection of an analog signal exceeding a predefined threshold. The filter is cleared as soon as ADC_ISR is read, so this filtering function must be used with the DMA controller and works only when using Interrupt mode (no polling).

The flag can be read on ADC_ISR.COMPE and can trigger an interrupt.

The high threshold and the low threshold can be read/write in the Compare Window register (ADC_CWR).

Depending on the sign of the conversion, chosen with ADC_EMR.SIGNMODE, the high threshold and low threshold values must be signed or unsigned to maintain consistency during the comparison. If the conversion is signed, both thresholds must also be signed; if the conversion is unsigned, both thresholds must be unsigned. If comparison occurs on all channels, SIGNMODE must be set to ALL_UNSIGNED or ALL_SIGNED and the thresholds must be set accordingly.

38.5.10 Differential and Single-ended Input Modes

38.5.10.1 Input-Output Transfer Functions

The ADC can be configured to operate in the following input voltage modes:

- Single-ended—ADC_CCR.DIFFx = 0. This is the default mode after a reset.
- Differential—ADC_CCR.DIFFx = 1 (see the figure Analog Full Scale Ranges in Single-ended/Differential Applications). In Differential mode, the ADC requires differential input signals with a VDD/2 common mode voltage (refer to the section “Electrical Characteristics”).

The following equations give the unsigned ADC input-output transfer function in each mode (see Note). With signed conversions (see ADC_EMR.SIGNMODE), subtract 2047 from the ADC_LCDR.LDATA value given below.

In the formulae below, REFP = ADVREFP, REFN = GNDIN33.

Single-ended mode:

$$\mathrm{ADC\_LCDR.LDATA} = \frac{\mathrm{ADx} - \mathrm{REFN}}{\mathrm{REFP} - \mathrm{REFN}} \times 2^{12}$$

Differential mode:

$$\text{ADC\_LCDR.LDATA} = \left(1 + \frac{\text{ADx} - \text{ADx+1}}{\text{REFP} - \text{REFN}}\right) \times 2^{11}$$

Note: Equations assume ADC_EMR.OSR = 1

If ADC_MR.ANACH is set, the ADC can manage both differential channels and single-ended channels. If ADC_MR.ANACH is cleared, the parameters defined in ADC_CCR are applied to all channels.

The following table gives the internal positive and negative ADC inputs assignment with respect to the programmed mode (ADC_CCR.DIFFx).

For example, if Differential mode is required on channel 0, input pins AD0 and AD1 are used. In this case, only channel 0 must be enabled by writing a 1 to ADC_CHER.CH0.

Figure 38-7. Analog Full Scale Ranges in Single-ended/Differential Applications

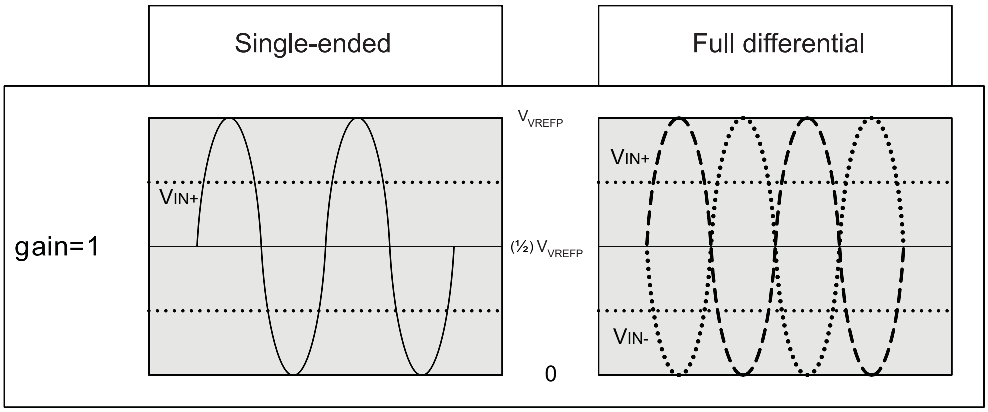


Table 38-1. Input Pins and Channel Numbers in Single-ended and Differential Modes

Internal ADC Inputs (VIN+, VIN-)		Channel Numbers

38.5.10.2 Alternate Multiplexer Selection (Safety)

The ADC Controller features an alternate input multiplexer that can be used to test the main input multiplexer in the context of safety-critical applications.

The alternate input multiplexer can be selected by enabling ADC_EMR.ALTCH. When selecting the alternate multiplexer, ADC_MR.TRACKTIM must be set to 15 and ADC_EMR.TRACKX must be set to 1.

38.5.11 ADC Timings

The ADC start-up time is programmed using ADC_MR.STARTUP. Refer to the section “Electrical Characteristics”.

The ADC Controller provides an inherent tracking time of six ADC clock cycles.

A minimal tracking time is necessary for the ADC to ensure the best converted final value between two conversions. The tracking time can be adjusted to accommodate a range of source impedances. If more than six ADC clock cycles are required, the tracking time can be increased by using ADC_MR.TRACKTIM and ADC_EMR.TRACKX.

⚠WARNING No input buffer amplifier to isolate the source is included in the ADC. Refer to the section “Electrical Characteristics”.

38.5.12 Temperature Sensor

The temperature sensor is internally connected to the channel with the highest index. For temperature measurement, ADC_TEMPMR.TEMPON must be set.

Temperature measurement can be performed in different ways through the ADC Controller. The different methods of measurement depend on configuration bits ADC_TRGR.TRGMOD and ADC_CHSR.CHmax (max=highest index).

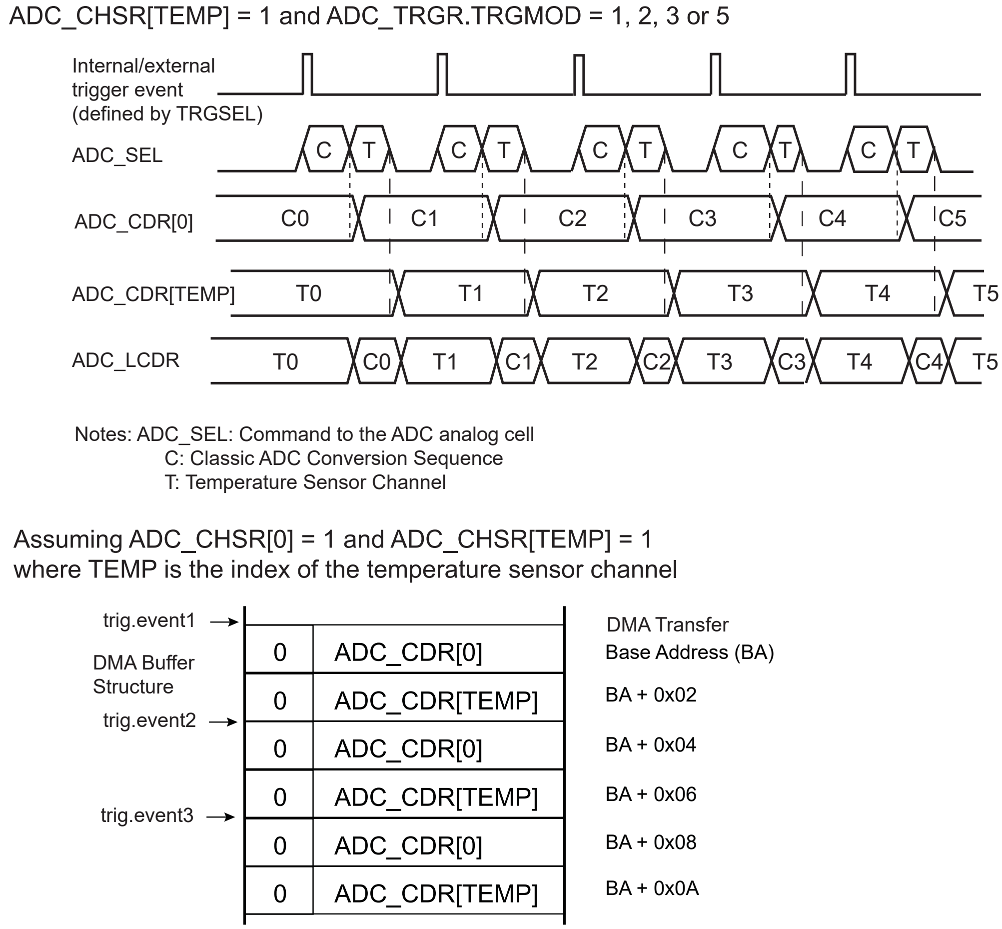
Temperature measurement can be triggered like the other channels by enabling its associated conversion channel, writing 1 in ADC_CHER.CHmax (max=highest index).

The manual start can only be performed if ADC_TRGR.TRGMOD = 0. When ADC_CR.START is set, the temperature sensor channel conversion is scheduled together with the other enabled channels (if any). The result of the conversion is placed in the ADC_CDRmax (max=highest index) register and the associated ADC_EOC_ISR.EOCmax (max=highest index) flag is set.

If ADC_TRGR.TRGMOD = 1, 2, 3 or 5, the temperature sensor channel is periodically converted together with other enabled channels and the result is placed on the ADC_LCDR and ADC_CDRmax (max=highest index) registers. Thus, the temperature conversion result is part of the DMA Controller buffer. The temperature channel can be enabled/disabled at any time but this may not be optimal for downstream processing.

When the conversion result matches the conditions defined in the ADC_TEMPMR and ADC_TEMPCWR, the ADC_ISR.TEMPCHG flag is set.

Figure 38-8. Non-optimized Temperature Conversion



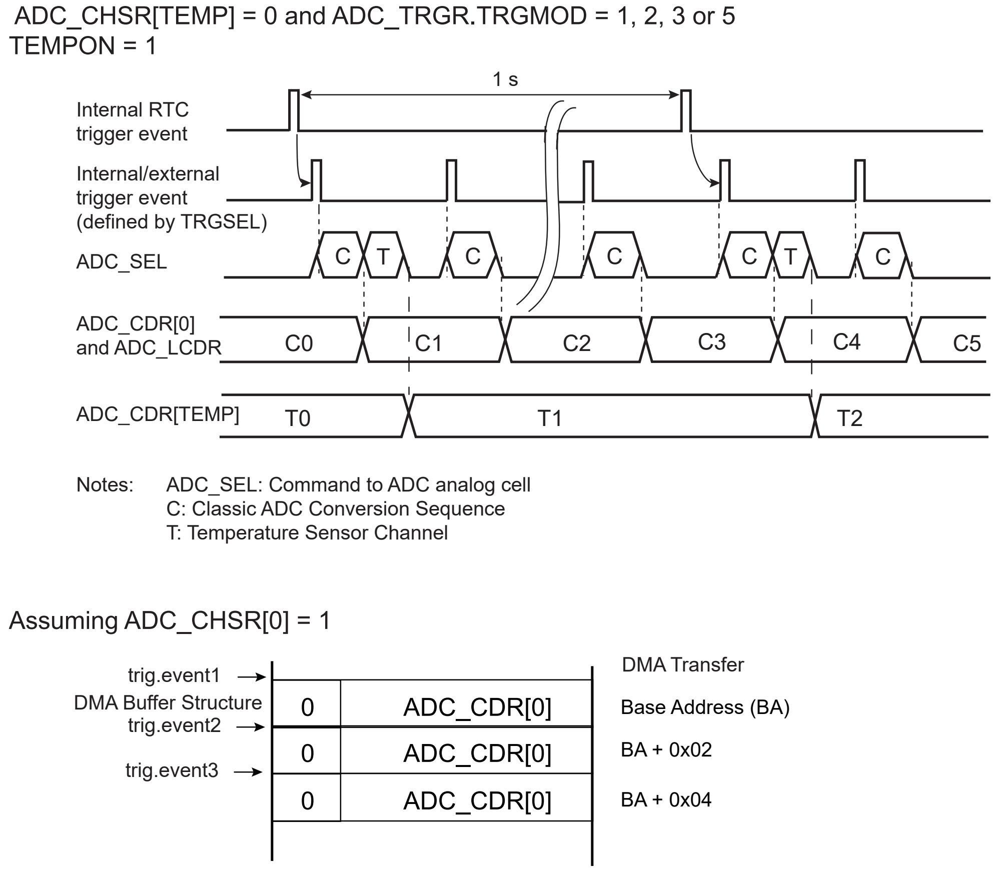
The temperature factor having a slow variation rate and being potentially totally different from the other conversion channels, the ADC Controller allows a different way of triggering the measure when ADC_TEMPMR.TEMPON is set but ADC_CHSR.CHmax (max=highest index) is not set.

Under these conditions, the measure is triggered every second by means of an internal trigger generated by the RTC, always enabled and totally independent of the internal/external triggers. The RTC event will be processed on the next internal/external trigger event, as described in the following figure. The internal/external trigger is selected through ADC_MR.TRGSEL.

In this mode of operation, the temperature sensor is only powered for a period of time covering the start-up time and conversion time (see the figure Temperature Conversion Only for more details).

Every second, a conversion is scheduled for the temperature channel but the result of the conversion is only uploaded in the ADC_CDRmax (max=highest index) register and not in ADC_LCDR. Therefore, there is no change in the structure of the DMA Controller buffer due to the conversion of the temperature channel, only the enabled channels are kept in the buffer. The end of conversion of the temperature channel is reported by the ADC_EOC_ISR.EOCmax (max=highest index) flag.

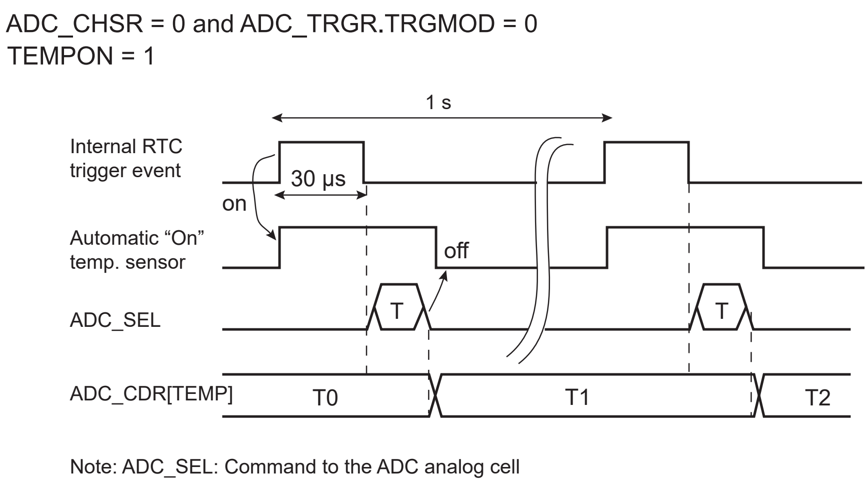
Figure 38-9. Optimized Temperature Conversion Combined With Classical Conversions



If TEMPON = 1, TRGMOD = 0 and none of the channels are enabled in ADC_CHSR (ADC_CHSR = 0), then only the temperature channel is converted at a rate of 1 conversion per second (see the figure Temperature Conversion Only).

This mode of operation, when combined with the Sleep mode operation of the ADC Controller, provides a low-power mode for temperature measurement (assuming there is no other ADC conversion to schedule at a high sampling rate, or simply no other channel to convert).

Figure 38-10. Temperature Conversion Only



Note: ADC_SEL: Command to the ADC analog cell

Furthermore, it is possible to raise a flag only if there is a predefined change in the temperature measure. The user can define a range of temperatures or a threshold in ADC_TEMPCWR, and the mode of comparison that can be programmed in ADC_TEMPMR.TEMPCMPMOD. These values define how the ADC_ISR.TEMPCHG flag is raised.

In any case, if TEMPON is set, the temperature can be read at anytime in ADC_CDRmax (max=highest index) without any specific software intervention.

38.5.13 Enhanced Resolution Mode and Digital Averaging Function

38.5.13.1 Enhanced Resolution Mode

The Enhanced Resolution mode is enabled if ADC_EMR.OSR is configured to 1, 2, 3 or 4. The enhancement is based on a digital averaging function.

There is no averaging on the last index channel if the measure is triggered by an RTC event.

In this mode, the ADC Controller will trade off conversion speed against accuracy by averaging multiple samples, thus providing a digital low-pass filter function.

The selected oversampling ratio applies to all enabled channels when triggered by an RTC event. The following formula applies:

$$\mathrm{ADC\_LCDR.LDATA} = \frac{1}{M} \times \sum_{k=0}^{k=N-1} ADC(k)$$

where N and M are given in the table below.

Table 38-2. Digital Averaging Function Configuration Versus OSR Values

ADC_EMR.OSR Value	ADC_LCDR.LDATA Length	N Value	M Value	Full Scale Value	Maximum Value
0	12 bits	1	1	4095	4095
1	13 bits	4	2	8191	8190
2	14 bits	16	4	16383	16381
3	15 bits	64	8	32767	32766
4	16 bits	256	16	65535	65533

The average result is valid in ADC_CDRx (x = channel index) only if the ADC_EOC_ISR.EOCn flag is set and if the ADC_OVER.OVREn flag is cleared. The average result for all channels is valid in ADC_LCDR only if ADC_ISR.DRDY is set and ADC_ISR.GOVRE is cleared.

Note that ADC_CDRs are not buffered. Therefore, when an averaging sequence is ongoing, the value in these registers changes after each averaging sample. However, overrun flags in ADC_OVER rise as soon as the first sample of an averaging sequence is received. Thus, the previous averaged value is not read, even if the new averaged value is not ready.

Consequently, when an overrun flag rises in ADC_OVER, it means that the previous unread data is lost but it does not mean that this data has been overwritten by the new averaged value, as the averaging sequence concerning this channel can still be ongoing.

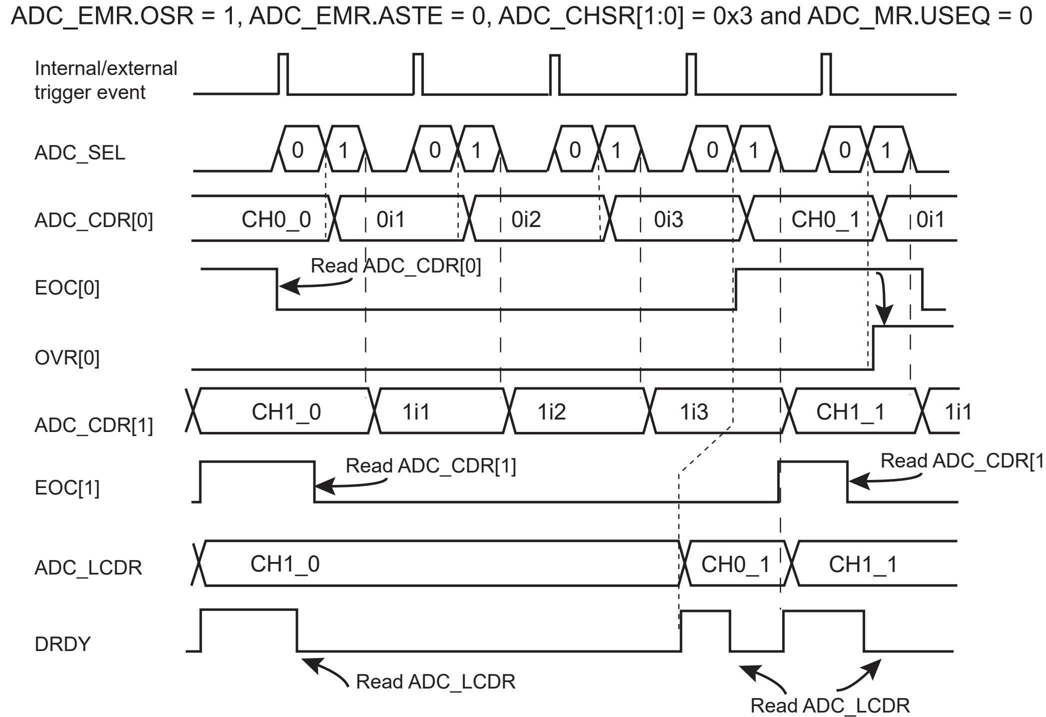
When an oversampling is performed, the maximum value that can be read on ADC_CDRx or ADC_LCDR is not the full-scale value, even if the maximum voltage is supplied on the analog input. See the table Digital Averaging Function Configuration Versus OSR Values.

38.5.13.2 Averaging Function Versus Trigger Events

The samples can be defined in different ways for the averaging function, depending on the configuration of ADC_EMR.ASTE and ADC_MR.USEQ.

When ADC_MR.USEQ = 0, there are two possible ways to generate the averaging through the trigger event. If ADC_EMR.ASTE = 0, every trigger event generates one sample for each enabled channel, as described in the following figure. Therefore, four trigger events are requested to obtain the result of averaging if ADC_EMR.OSR = 1.

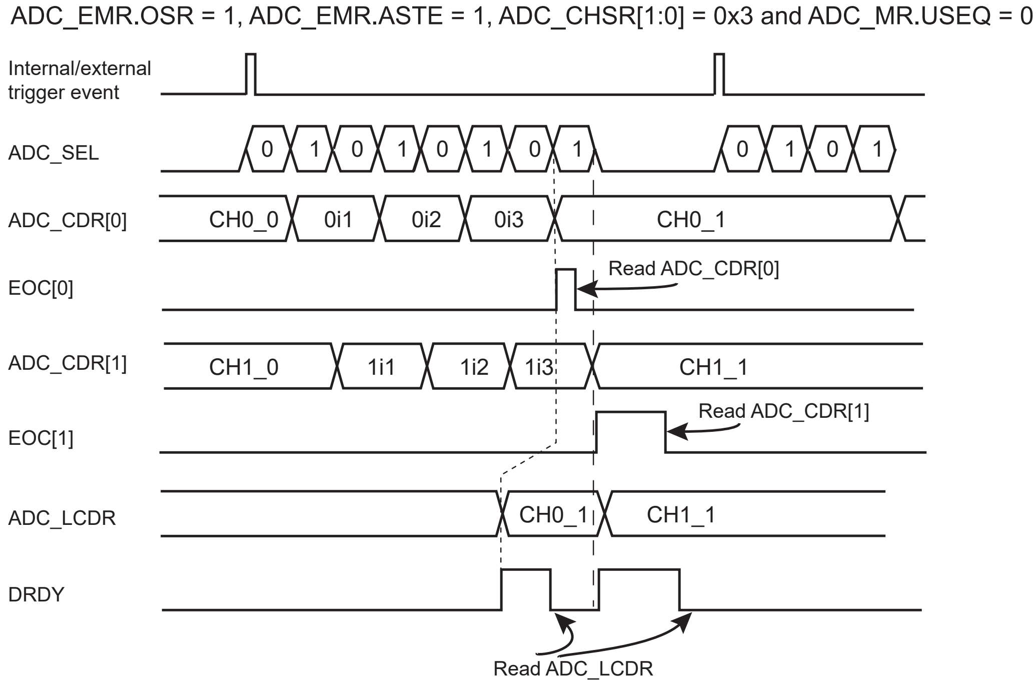
Figure 38-11. Digital Averaging Function Waveforms Over Multiple Trigger Events



Note: ADC_SEL: Command to the ADC analog cell
0i1, 0i2, 0i3, 1i1, 1i2, 1i3 are intermediate results and CH0_0, CH0_1, CH1_0 and CH1_1 are final results of average function.

If ADC_EMR.ASTE = 1 and ADC_MR.USEQ = 0, the sequence to be converted, defined in ADC_CHSR, is automatically repeated n times (where n corresponds to the oversampling ratio defined in ADC_EMR.OSR). As a result, only one trigger is required to obtain the result of the averaging function, as described in the following figure.

Figure 38-12. Digital Averaging Function Waveforms on a Single Trigger Event



Note: ADC_SEL: Command to the ADC analog cell
0i1, 0i2, 0i3, 1i1, 1i2, 1i3 are intermediate results and CH0_0, CH0_1, CH1_0 and CH1_1 are final results of average function.

When USEQ = 1, the user can define the channel sequence to be converted by configuring ADC_SEQRx and ADC_CHER so that channels are not interleaved during the averaging period. Under these conditions, a sample is defined for each end of conversion, as described in the following figure.

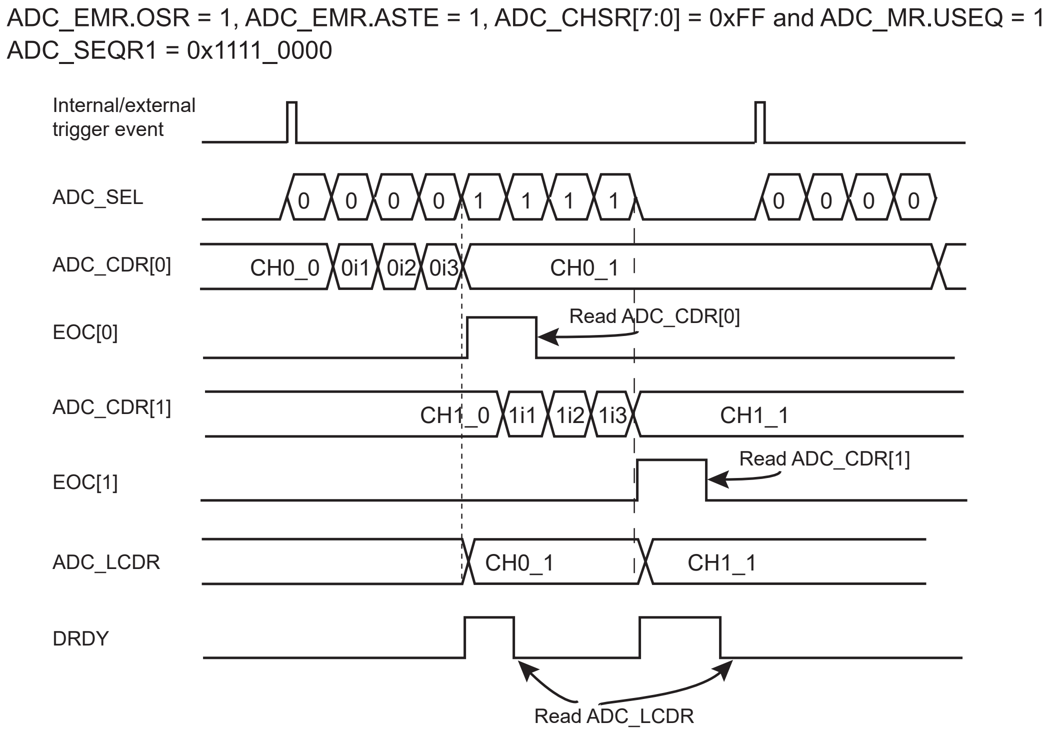
When USEQ = 1 and ASTE = 1, OSR can be only configured to 1. Up to three channels can be converted in this mode. The averaging result will be placed in the corresponding ADC_CDRx and in ADC_LCDR for each trigger event. The ADC real sample rate remains the maximum ADC sample rate divided by 4.

It is important that the user sequence follows a specific pattern. The user sequence must be programmed in such a way that it generates a stream of conversion, where a same channel is successively converted.

Table 38-3. Example Sequence Configurations (USEQ = 1, ASTE = 1, OSR = 1)

Register	Number of Channels Non-interleaved Averaging - Register Value		
	1 (e.g., CH0)	2 (e.g., CH0, CH1)	3 (e.g., CH0, CH1, CH2)
ADC_CHSR	0x0000000F	0x000000FF	0x00000FFF
ADC_SEQR1	0x00000000	0x11110000	0x11110000
ADC_SEQR2	0x00000000	0x00000000	0x00002222

Figure 38-13. Digital Averaging Function Waveforms on a Single Trigger Event, Non-interleaved



Note: ADC_SEL: Command to the ADC analog cell
0i1, 0i2, 0i3, 1i1, 1i2, 1i3 are intermediate results and CH0_0, CH0_1, CH1_0 and CH1_1 are final results of average function.

38.5.14 Automatic Error Correction

The ADC features automatic error correction of conversion results. Offset and gain error corrections are available. The correction can be enabled for each channel and correction values (offset and gain) are the same for all channelsprogrammable per channel.

To enable error correction, the corresponding ECORRx bit must be set in the Channel Error Correction register (ADC_CECR). The offset and gain values used to compensate the results are the same for all correction-enabled channels and programmed in the Correction Values register (ADC_CVR) set on a ‘per channel’ basis using the Correction Select register (ADC_COSR) and the Correction Values register (ADC_CVR). ADC_COSR is used to select the channel to be displayed in ADC_CVR. This selection applies to both the read and the write operations in ADC_CVR.

ADC_EMR.ADCMODE is used to configure a running mode of the ADC Normal mode, Offset Error mode, or Gain Error mode (see ADC_EMR). ADCMODE uses two internal references (ADVREFP, GNDIN33) to be measured and to extract the offset and gain error from 3 point-measurement codes. If some references already exist on the final application connected to some input channel ADx, they can be used as a replacement of the ADCMODE to generate the 2 or 3 points of calibration and used to extract the GAINCORR and OFFSETCORR.

After a reset, the ADC running mode is Normal mode. Offset Error mode and Gain Error mode are used to determine values of offset compensation and gain compensation, respectively, to apply to conversion results. The following table provides formulas to obtain the compensation values, with:

- OFFSETCORR—the Offset Correction value. OFFSETCORR is a signed value.
- GAINCORR—the Gain Correction value
- GCi—the intermediate Gain Compensation value
- Gs—the value 13
- ConvValue—the value converted by the ADC (as returned in ADC_LCDR or ADC_CDR)
- Resolution—the resolution used to process the conversion (either RESOLUTION, RESOLUTION+1 or RESOLUTION+2).

Table 38-4. ADC Running Modes

ADC_EMR.ADCMODE	Mode	Description
0	Normal	Normal mode of operation to perform conversions
1	Offset Error	For unsigned conversions: OFFSETCORR = ConvValue − $2^{(\text{Resolution} - 1)}$
		For signed conversions: OFFSETCORR = ConvValue
2	Gain Error	GCi = ConvValue
3		$\text{GAINCORR} = \frac{3584}{\text{GCi} - \text{ConvValue}} \times 2^{(\text{Gs})}$

The final conversion result after error correction is obtained using the following formula:

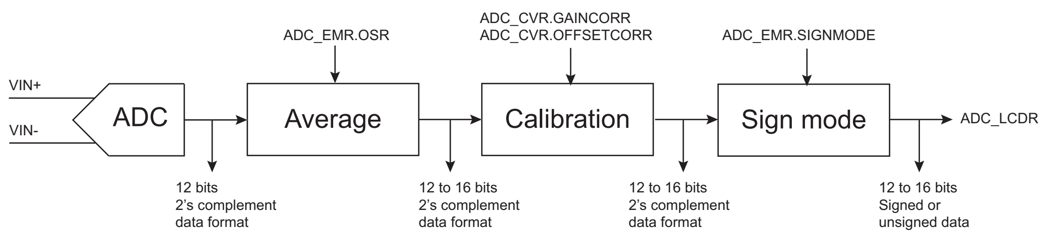
$$\text{Corrected Data} = (\text{Converted Data} + \text{OFFSETCORR}) \times \frac{\text{GAINCORR}}{2^{(\text{Gs})}}$$

38.5.14.1 Calibration Mode of Operation

The ADC is built to convert positive and negative voltages around a common mode voltage (ADVREFP-GNDIN33)/2. This is why the ADC output, averaging and calibration are performed as 2's complements. An ADC positive integer output is generated only in the last stage to generate unsigned data.

The ADC code is first averaged when requested; calibration is applied afterward. See the following figure.

Figure 38-14. ADC Signal Processing



Three internal reference voltages, VM, VL and VH, are generated from ADVREFP, with:

- VL = (ADVREFP-GNDIN33)x(1/16)
- VH = (ADVREFP-GNDIN33) x(15/16)
- VM = (ADVREFP-GNDIN33)/2

In Single mode non-signed outputs, the references are ideally converted as:

- VL_code = 256
- VH_code = 3840
- VM_code = 2048

In Differential mode signed outputs, the references are ideally converted as:

- (VL-VH)_code = -1792
- (VH-VL)_code = +1792
- VM_code = 0

The difference between the two voltage reference codes is the value 3584.

For calibration, three values are measured using ADCMODE 1,2,3.

In the table ADC Running Modes, ConvValue is the current converted value.

38.5.14.1.1 First Conversion in ADCMODE=1

The ADC converted value is placed in the OFFSETCORR field (even after averaging) in a Sign mode signed output. If the output is unsigned, subtract half the code dynamic, which depends on the resolution (averaging).

OFFSETCORR is the offset at mid-range in an unsigned configuration.

38.5.14.1.2 Second Conversion in ADCMODE=2

This gives an upper code for gain calculation:

ADC output VH_Code = GCi = ConvValue

38.5.14.1.3 Third Conversion in ADCMODE=3

This gives the lowest code for the gain calculation:

ADC output VL_code = new ConvValue

Finally, VH_Code-VL_Code = GCI-ConvValue is the spread between the two codes, ideally at 3584 when there is no gain error.

38.5.14.1.4 Final GAINCORR Computation

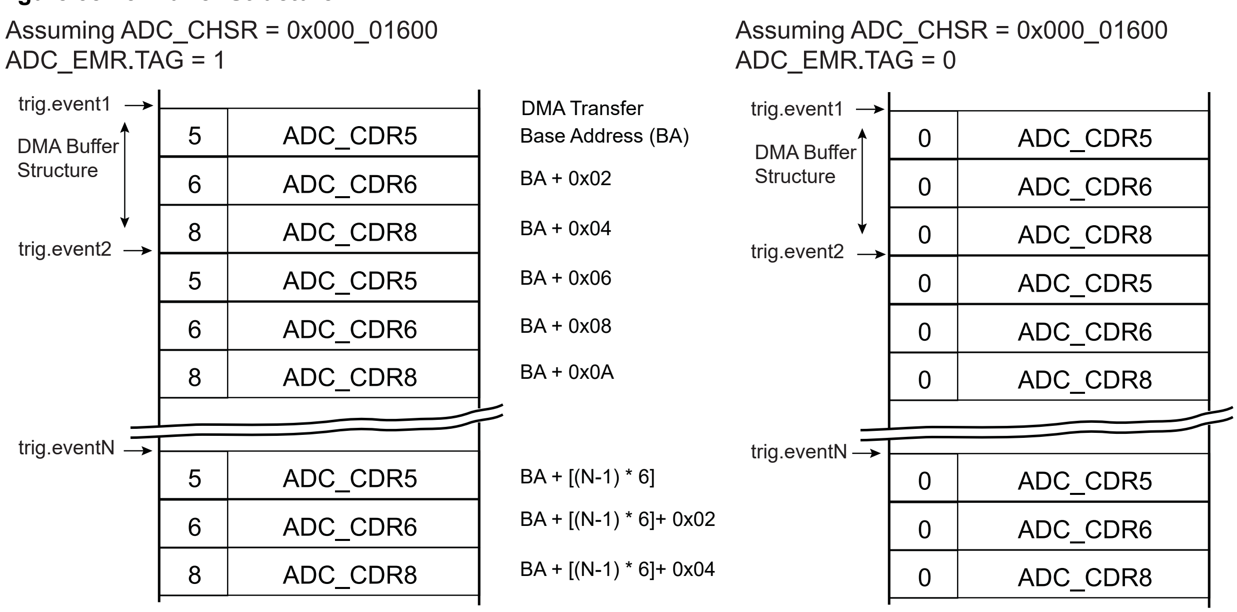
The final formula to compute GAINCORR can be applied. This formula is given without averaging (ADC resolution at 12 bits).

If an averaging is applied to get the ADC code in ADCMODE 2 and 3, then it is needed to scale down the output code to fit a 12-bit resolution.

38.5.15 Buffer Structure without FIFO

The DMA read channel is triggered when ADC_FMR.ENFIFO is set to 0 (see ENFIFO: Enable FIFO) and each time a new data is stored in ADC_LCDR. The same structure of data is repeatedly stored in ADC_LCDR each time a trigger event occurs. Depending on the user mode of operation (ADC_MR, ADC_CHSR, ADC_SEQR1, ADC_SEQR2, ADC_TSMR), the structure differs. Each data read to DMA buffer, carried on a half-word (16 bits), consists of last converted data right-aligned and when TAG is set in ADC_EMR, the four most significant bits carry the channel number, thus allowing an easier post-processing in the DMA buffer or a better checking of the DMA buffer integrity.

Figure 38-15. Buffer Structure



.

38.5.15.1 Classic ADC Channels Only

The structure of data within the buffer is defined by ADC_MR, ADC_CHSR, ADC_SEQRx. See the figure Buffer Structure.

If the user sequence is not used (i.e., ADC_MR.USEQ is cleared), then only the value of ADC_CHSR defines the data structure. For each trigger event, enabled channels are consecutively stored in ADC_LCDR and automatically read to the buffer.

When the user sequence is configured (i.e., ADC_MR.USEQ is set), not only does ADC_CHSR modify the data structure of the buffer, but ADC_SEQRx registers may modify the data structure of the buffer as well.

38.5.16 Buffer Structure with FIFO

The DMA read channel is triggered when the fields ENFIFO, ENLEVEL and CHUNK are used (see ADC_FMR).

If the configuration ENFIFO is high and ENLEVEL is low, the DMA read channel is triggered as soon as one data is written.

When at least one data is ready in the FIFO, the RXRDY flag rises and remains high as long as there is at least one data to be read in the FIFO. When the entire FIFO has been filled with data, the RXFULL flag rises. If a new data is written into the RX FIFO while RXFULL is high, then the RXOVR flag rises. This flag remains high until ADC_ISR is read.

Once all data contained in the RX FIFO have been read, the RXEMPTY flag rises. If a data is read while the RX FIFO is empty, an underrun occurs and the RXUDR flag rises. This flag remains high until ADC_ISR is read.

Once a data is written in the RX FIFO, the RXRDY flag rises. If the corresponding interrupt has been enabled, an interrupt is generated and remains high as long as a data is available in the RX FIFO.

The FIFO features chunk management. When the number of filled spaces reaches the chunk size defined by ADC_FMR.CHUNK, the DMA read channel is triggered and the RXCHUNK flag is raised, ensuring that chunk size data can be read consecutively. This flag is reset once CHUNK data are read. This chunk definition can be used with the DMA to define how many accesses can be performed. In this case, the chosen chunk size must match the chunk value defined in the DMA.

The DMA read channel is triggered when a new data is stored in FIFO. The same structure of data is repeatedly stored in FIFO each time a trigger event occurs. Depending on the user mode of operation (ADC_MR, ADC_CHSR, ADC_SEQR1, ADC_SEQR2, ADC_TSMR), the structure differs. Each data read to DMA buffer, carried on a half-word (16 bits), consists of last converted data right-aligned, and when ADC_EMR.TAG is set, the four most significant bits carry the channel number, thus allowing an easier post-processing in the DMA buffer or a better checking of the DMA buffer integrity.

ADC_FMR.FIFOCNT gives the number of conversions available in the FIFO.

38.5.17 Fault Event

The ADC Controller internal fault output is directly connected to the PWM fault input. The fault event may be asserted depending on the configuration of comparison registers and converted values.

Two types of comparison trigger a fault event sent to the PWM:

- The first comparison type is based on ADC_CWR settings, i.e., on all converted channels except the last one;
- The second comparison type is linked to the last channel (ADC_TEMPCWR settings) where the temperature is measured.

As an example, overcurrent and temperature values exceeding user-defined limits trigger a fault to the PWM.

When the comparison event occurs, the ADC fault output generates a pulse of one peripheral clock cycle to the PWM fault input. This fault line can be enabled or disabled within PWM. Should it be activated and asserted by the ADC Controller, the PWM outputs are immediately placed in a safe state (pure combinational path). Note that the ADC fault output connected to the PWM is not the COMPE bit. Thus, the Fault mode (FMOD) within the PWM configuration must be FMOD = 1.

38.5.18 Register Write Protection

To prevent any single software error from corrupting ADC behavior, certain registers in the address space can be write-protected by setting the bits WPEN and WPITEN in the ADC Write Protection Mode Register (ADC_WPMR).

If a write access to the protected registers is detected, the WPVS flag in the ADC Write Protection Status Register (ADC_WPSR) is set and the field WPVSRC indicates the register in which the write access has been attempted.

The WPVS flag is automatically reset by reading ADC_WPSR.

The following registers are write-protected when ADC_WPMR.WPEN is set:

- ADC Mode Register
- ADC Channel Sequence Register 1
- ADC Channel Sequence Register 2

- ADC Channel Enable Register
- ADC Channel Disable Register
- ADC Temperature Sensor Mode Register
- ADC Temperature Compare Window Register
- ADC Extended Mode Register
- ADC FIFO Mode Register
- ADC Compare Window Register
- ADC Channel Configuration Register
- ADC Analog Control Register
- ADC Trigger Register
- ADC Correction Select Register
- ADC Correction Values Register
- ADC Channel Error Correction Register

The following registers are write-protected when ADC_WPMR.WPITEN is set:

- ADC Interrupt Enable Register
- ADC Interrupt Disable Register

The following register is write-protected when ADC_WPMR.WPCREN is set:

- ADC Control Register

38.6.1 ADC Control Register

Name: ADC_CR
Offset: 0x00
Reset: –
Property: Write-only

This register can only be written if the WPCREN bit is cleared in the ADC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
				CMPRST	SWFIFO		START	SWRST
Access				W	W		W	W
Reset				–	–		–	–

Bit 4 – CMPRST Comparison Restart

Value	Description
0	No effect.
1	Stops the conversion result storage until the next comparison match.

Bit 3 – SWFIFO Software FIFO Reset

Value	Description
0	No effect.
1	Resets the internal FIFO, simulating a hardware reset.

Bit 1 – START Start Conversion

Value	Description
0	No effect.
1	Begins analog-to-digital conversion.

Bit 0 – SWRST Software Reset

Value	Description
0	No effect.
1	Resets the ADC, simulating a hardware reset.

38.6.2 ADC Mode Register

Name: ADC_MR
Offset: 0x04
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the ADC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
	USEQ	ALWAYS1	TRANSFER[1:0]		TRACKTIM[3:0]			
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0
Bit	23	22	21	20	19	18	17	16
	ANACH				STARTUP[3:0]			
Access	R/W				R/W	R/W	R/W	R/W
Reset	0				0	0	0	0
Bit	15	14	13	12	11	10	9	8
	PRESCAL[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
		FWUP	SLEEP		TRGSEL[2:0]			
Access		R/W	R/W		R/W	R/W	R/W	
Reset		0	0		0	0	0	

Bit 31 – USEQ User Sequence Enable

Value	Name	Description
0	NUM_ORDER	Normal mode: The controller converts channels in a simple numeric order depending only on the channel index.
1	REG_ORDER	User Sequence mode: The sequence respects what is defined in ADC_SEQR1 and ADC_SEQR2 and can be used to convert the same channel several times.

Bit 30 – ALWAYS1 Must always be written to 1

Bits 29:28 – TRANSFER[1:0] Transfer Time
Must be set to 2 to ensure the optimal transfer time.

Bits 27:24 – TRACKTIM[3:0] Tracking Time

ADC_EMR.TRACKX	TRACKTIM		
	0 to 3	4 to 14	15
0	$6 \times t_{ADCCLK}$		$7 \times t_{ADCCLK}$
1	$6 \times t_{ADCCLK}$	$([4 \times (TRACKTIM + 1)] - 10) \times t_{ADCCLK}$	
2	Not Applicable	$([8 \times (TRACKTIM + 1)] - 10) \times t_{ADCCLK}$	
3	Not Applicable	$([16\times (TRACKTIM + 1)] - 10) \times t_{ADCCLK}$	

Bit 23 – ANACH Analog Change

Value	Name	Description
0	NONE	No analog change on channel switching: DIFF0 is used for all channels.
1	ALLOWED	Allows different analog settings for each channel. See ADC_CCR.

Bits 19:16 – STARTUP[3:0] Start-Up Time

Value	Name	Description
0	SUT0	0 period of ADCCLK
1	SUT8	8 periods of ADCCLK
2	SUT16	16 periods of ADCCLK
3	SUT24	24 periods of ADCCLK
4	SUT64	64 periods of ADCCLK
5	SUT80	80 periods of ADCCLK
6	SUT96	96 periods of ADCCLK
7	SUT112	112 periods of ADCCLK
8	SUT512	512 periods of ADCCLK
9	SUT576	576 periods of ADCCLK
10	SUT640	640 periods of ADCCLK
11	SUT704	704 periods of ADCCLK
12	SUT768	768 periods of ADCCLK
13	SUT832	832 periods of ADCCLK
14	SUT896	896 periods of ADCCLK
15	SUT960	960 periods of ADCCLK

Bits 15:8 – PRESCAL[7:0] Prescaler Rate Selection
PRESCAL = ($f_{peripheral\ clock}$ / (2 × f_{ADCCLK})) – 1.

Bit 6 – FWUP Fast Wakeup

Value	Name	Description
0	OFF	If SLEEP is 1, then both ADC core and reference voltage circuitry are OFF between conversions.
1	ON	If SLEEP is 1, then Fast Wake-up Sleep mode: The voltage reference is ON between conversions and ADC core is OFF.

Bit 5 – SLEEP Sleep Mode

Value	Name	Description
0	NORMAL	Normal mode: The ADC core and reference voltage circuitry are kept ON between conversions.
1	SLEEP	Sleep mode: The wake-up time can be modified by programming the FWUP bit.

Bits 3:1 – TRGSEL[2:0] Trigger Selection
The trigger selection can be performed only if ADC_TRGR.TRGMOD = 1, 2 or 3.

Value	Name	Description
0	ADC_TRIG0	ADTRG
1	ADC_TRIG1	TIOA0 TC0
2	ADC_TRIG2	TIOA1 TC0
3	ADC_TRIG3	TIOA2 TC0
4	ADC_TRIG4	TIOA0_TC1
5	ADC_TRIG5	ACC
6	ADC_TRIG6	PWM event line 0
7	ADC_TRIG7	RTCOUT0

38.6.3 ADC Channel Sequence Register 1

Name: ADC_SEQR1
Offset: 0x08
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the ADC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
	USCH8[3:0]				USCH7[3:0]			
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	USCH6[3:0]				USCH5[3:0]			
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	USCH4[3:0]				USCH3[3:0]			
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	USCH2[3:0]				USCH1[3:0]			
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 0:3, 4:7, 8:11, 12:15, 16:19, 20:23, 24:27, 28:31, 32:35 – USCHx User Sequence Number x
The allowed range is 0 to 15, thus only a CH0 to CH15 sequence can be used.
This register can be used only if ADC_MR.USEQ is set to ‘1’.
Any USCHx field is processed only if the bit CHx-1 in ADC_CHSR reads logical ‘1’, else any value written in USCHx does not add the corresponding channel in the conversion sequence.
Configuring the same value in different fields leads to multiple samples of the same channel during the conversion sequence. This can be done consecutively, or not, according to user needs.
Example: For each trigger event, to obtain the “CH3 CH1 CH0 CH4 CH4” conversion sequence, use the following settings:
ADC_SEQR1.USCH1=3, ADC_CHSR.CH0=1
ADC_SEQR1.USCH2=1, ADC_CHSR.CH1=1
ADC_SEQR1.USCH3=0, ADC_CHSR.CH2=1
ADC_SEQR1.USCH4=4, ADC_CHSR.CH3=1
ADC_SEQR1.USCH5=4, ADC_CHSR.CH4=1

38.6.4 ADC Channel Sequence Register 2

Name: ADC_SEQR2
Offset: 0x0C
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the ADC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
	USCH16[3:0]				USCH15[3:0]			
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	USCH14[3:0]				USCH13[3:0]			
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	USCH12[3:0]				USCH11[3:0]			
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	USCH10[3:0]				USCH9[3:0]			
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 0:3, 4:7, 8:11, 12:15, 16:19, 20:23, 24:27, 28:31 – USCHx User Sequence Number x
The allowed range is 0 to 15, thus only a CH0 to CH15 sequence can be used.
This register can be used only if ADC_MR.USEQ is set to ‘1’.
Any USCHx field is processed only if the CHx-1 bit in ADC_CHSR reads logical ‘1’, else any value written in USCHx does not add the corresponding channel in the conversion sequence.
Configuring the same value in different fields leads to multiple samples of the same channel during the conversion sequence. This can be done consecutively, or not, according to user needs.

38.6.5 ADC Channel Enable Register

Name: ADC_CHER
Offset: 0x10
Reset: –
Property: Write-only

If ADC_MR.USEQ = 1, CHx corresponds to the enable of sequence number x+1 described in ADC_SEQR1 and ADC_SEQR2 (e.g. CH0 enables sequence number USCH1). For example, if Differential mode is required on channel 0, input pins AD0 and AD1 are used. In this case, only channel 0 must be enabled by writing a 1 to ADC_CHER.CH0.

This register can only be written if the WPEN bit is cleared in the ADC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
	CH31	CH30						
Access	W	W						
Reset	–	–						

Bit	23	22	21	20	19	18	17	16

Reset								

Bit	15	14	13	12	11	10	9	8
	CH15	CH14	CH13	CH12	CH11	CH10	CH9	CH8
Access	W	W	W	W	W	W	W	W
Reset	–	–	–	–	–	–	–	–

Bit	7	6	5	4	3	2	1	0
	CH7	CH6	CH5	CH4	CH3	CH2	CH1	CH0
Access	W	W	W	W	W	W	W	W
Reset	–	–	–	–	–	–	–	–

Bits 30, 31 – CH30, CH31 Channel x Enable

Value	Description
0	No effect.
1	Enables the corresponding channel.

Bits 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15 – CHx Channel x Enable

Value	Description
0	No effect.
1	Enables the corresponding channel.

38.6.6 ADC Channel Disable Register

Name: ADC_CHDR
Offset: 0x14
Reset: –
Property: Write-only

This register can only be written if the WPEN bit is cleared in the ADC Write Protection Mode Register.

⚠WARNING If the corresponding channel is disabled during a conversion, or if it is disabled and then reenabled during a conversion, its associated data and corresponding ADC_EOC_ISR.EOCx, ADC_ISR.GOVRE and ADC_OVER.OVREx flags are unpredictable.

Bit	31	30	29	28	27	26	25	24
	CH31	CH30						
Access	W	W						
Reset	–	–						

Bit	23	22	21	20	19	18	17	16
Access

Access	W	W	W	W	W	W	W	W
Reset	–	–	–	–	–	–	–	–

Bit	7	6	5	4	3	2	1	0
	CH7	CH6	CH5	CH4	CH3	CH2	CH1	CH0
Access	W	W	W	W	W	W	W	W
Reset	–	–	–	–	–	–	–	–

Bits 30, 31 – CH30, CH31 Channel x Disable

Value	Description
0	No effect.
1	Disables the corresponding channel.

Bits 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15 – CHx Channel x Disable

Value	Description
0	No effect.
1	Disables the corresponding channel.

38.6.7 ADC Channel Status Register

Name: ADC_CHSR
Offset: 0x18
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
	CH31	CH30						
Access	R	R						
Reset	0	0						

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
	CH15	CH14	CH13	CH12	CH11	CH10	CH9	CH8
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	CH7	CH6	CH5	CH4	CH3	CH2	CH1	CH0
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bits 30, 31 – CH30, CH31 Channel x Status

Value	Description
0	The corresponding channel (or part of sequence, see ADC_SEQyR.USCHx) is disabled..
1	The corresponding channel (or part of sequence, see ADC_SEQyR.USCHx) is enabled.

Bits 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15 – CHx Channel x Status
As an example, when ADC_MR.USEQ=1 and ADC_CHSR.CH2=1, the channel configured in ADC_SEQ1R.USCH3 is part of the sequence of conversions.

Value	Description
0	The corresponding channel (or part of sequence, see ADC_SEQyR.USCHx) is disabled..
1	The corresponding channel (or part of sequence, see ADC_SEQyR.USCHx) is enabled.

38.6.8 ADC Last Converted Data Register

Name: ADC_LCDR
Offset: 0x20
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
				CHNBOSR[4:0]				
Access				R	R	R	R	R
Reset				0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
	LDATA[15:8]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	LDATA[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bits 28:24 – CHNBOSR[4:0] Channel Number in Oversampling Mode
Indicates the last converted channel when ADC_EMR.TAG is set and ADC_EMR.OSR is not equal to 0. If ADC_EMR.TAG is not set, CHNBOSR = 0.

Bits 15:0 – LDATA[15:0] Last Data Converted
The analog-to-digital conversion data is placed into this register at the end of a conversion and remains until a new conversion is completed.
If OSR = 0 and TAG = 1 in ADC_EMR, the 4 MSBs of LDATA carry the channel number to obtain a packed system memory buffer made of 1 converted data stored in a half-word (16 bits) instead of 1 converted data in a 32-bit word, thus dividing by 2 the size of the memory buffer. See ADC_LCDR (NO_OSR).

38.6.9 ADC Last Converted Data Register (NO_OSR)

Name: ADC_LCDR (NO_OSR)
Offset: 0x20
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
	NO_OSR_CHNBOSR[3:0]				NO_OSR_LDATA[11:8]			
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	NO_OSR_LDATA[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bits 15:12 – NO_OSR_CHNBOSR[3:0] Channel Number when No Oversampling
Indicates the last converted channel when ADC_EMR.TAG is set and the ADC_EMR.OSR = 0. If ADC_EMR.TAG is not set, NO_OSR_CHNB = 0.

Bits 11:0 – NO_OSR_LDATA[11:0] Last Data Converted when No Oversampling
The analog-to-digital conversion data is placed into this register at the end of a conversion and remains until a new conversion is completed.

38.6.10 ADC Interrupt Enable Register

Name: ADC_IER
Offset: 0x24
Reset: –
Property: Write-only

This register can only be written if the WPITEN bit is cleared in the ADC Write Protection Mode Register.

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Enables the corresponding interrupt.

Bit	31	30	29	28	27	26	25	24
						COMPE	GOVRE	DRDY
Access						W	W	W
Reset						–	–	–

Bit	23	22	21	20	19	18	17	16
					TEMPCHG	EOS		
Access					W	W

Bit	7	6	5	4	3	2	1	0
			RXOVR	RXUDR	RXCHUNK	RXFULL	RXEMPTY	RXRDY
Access			W	W	W	W	W	W
Reset			–	–	–	–	–	–

Bit 26 – COMPE Comparison Event Interrupt Enable

Bit 25 – GOVRE General Overrun Error Interrupt Enable

Bit 24 – DRDY Data Ready Interrupt Enable

Bit 19 – TEMPCHG Temperature Change Interrupt Enable

Bit 18 – EOS End Of Sequence Interrupt Enable

Bit 5 – RXOVR Receive Over Flow Interrupt Enable

Bit 4 – RXUDR Receive Under Flow Interrupt Enable

Bit 3 – RXCHUNK Receive FIFO Chunk Interrupt Enable

Bit 2 – RXFULL Receive FIFO Full Interrupt Enable

Bit 1 – RXEMPTY Receive FIFO Empty Interrupt Enable

Bit 0 – RXRDY Receive Ready Interrupt Enable

38.6.11 ADC Interrupt Disable Register

Name: ADC_IDR
Offset: 0x28
Reset: –
Property: Write-only

This register can only be written if the WPITEN bit is cleared in the ADC Write Protection Mode Register.

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Disables the corresponding interrupt.

Bit	31	30	29	28	27	26	25	24
						COMPE	GOVRE	DRDY
Access						W	W	W
Reset						–	–	–
Bit	23	22	21	20	19	18	17	16

Reset			0	0	0	0	0	0

Bit 26 – COMPE Comparison Event Interrupt Mask

Bit 25 – GOVRE General Overrun Error Interrupt Mask

Bit 24 – DRDY Data Ready Interrupt Mask

Bit 19 – TEMPCHG Temperature Change Interrupt Disable

Bit 18 – EOS End Of Sequence Interrupt Mask

Bit 5 – RXOVR Receive Over Flow Interrupt Mask

Bit 4 – RXUDR Receive Under Flow Interrupt Mask

Bit 3 – RXCHUNK Receive FIFO Chunk Interrupt Mask

Bit 2 – RXFULL Receive FIFO Full Interrupt Mask

Bit 1 – RXEMPTY Receive FIFO Empty Interrupt Mask

Bit 0 – RXRDY Receive Ready Interrupt Mask

38.6.13 ADC Interrupt Status Register

Name: ADC_ISR
Offset: 0x30
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
						COMPE	GOVRE	DRDY
Access						R	R	R
Reset						0	0	0
Bit	**23**	**22**	**21**	**20**	**19**	**18**	**17**	**16**
					TEMPCHG	EOS		
Access					R	R		
Reset					0	0

			RXOVR	RXUDR	RXCHUNK	RXFULL	RXEMPTY	RXRDY
Access			R	R	R	R	R	R
Reset			0	0	0	0	0	0

Bit 26 – COMPE Comparison Event (cleared on read)

Value	Description
0	No comparison event occurred since the last read of ADC_ISR.
1	At least one comparison event (defined in ADC_EMR and ADC_CWR) has occurred since the last read of ADC_ISR.

Bit 25 – GOVRE General Overrun Error (cleared on read)

Value	Description
0	No general overrun error occurred since the last read of ADC_ISR.
1	At least one general overrun error has occurred since the last read of ADC_ISR.

Bit 24 – DRDY Data Ready (automatically set / cleared)

Value	Description
0	No data has been converted since the last read of ADC_LCDR.
1	At least one data has been converted and is available in ADC_LCDR.

Bit 19 – TEMPCHG Temperature Change (cleared on read)

Value	Description
0	There is no comparison match (defined in the Temperature Compare Window register (ADC_TEMPCWR) since the last read of ADC_ISR.
1	The temperature value reported on ADC_CDRmax (max=highest index) has changed since the last read of ADC_ISR, according to what is defined in ADC_TEMPTMR and ADC_TEMPCWR.

Bit 18 – EOS End Of Sequence (cleared on read)

Value	Description
0	No sequence is in progress or the sequence is not finished. This flag is cleared when reading ADC_ISR.
1	The sequence is complete.

Bit 5 – RXOVR Receive Over Flow (cleared on read)

Value	Description
0	No general overrun error occurred since the last read of ADC_ISR.
1	At least one general overrun error has occurred since the last read of ADC_ISR.

Bit 4 – RXUDR Receive Under Flow (cleared on read)

Value	Description
0	No general underrun error occurred since the last read of ADC_ISR.
1	At least one general underrun error has occurred since the last read of ADC_ISR.

Bit 3 – RXCHUNK Receive FIFO Chunk (cleared on read)

Value	Description
0	The number of written elements in the FIFO has been lower than or not equal to chunk_size since the last read of ADC_ISR.
1	The number of written elements in the FIFO has been greater than or equal to chunk_size since the last read of ADC_ISR.

Bit 2 – RXFULL Receive FIFO Full (cleared on read)

Value	Description
0	FIFO has not been full since the last read of ADC_ISR.
1	FIFO has been full since the last read of ADC_ISR.

Bit 1 – RXEMPTY Receive FIFO Empty (cleared on read)

Value	Description
0	FIFO has not been empty since the last read of ADC_ISR.
1	FIFO has been empty since the last read of ADC_ISR.

Bit 0 – RXRDY Receive Ready (cleared on read)

Value	Description
0	FIFO has been empty since the last read of ADC_ISR.
1	One element has been written since the last read of ADC_ISR.

38.6.14 ADC End Of Conversion Interrupt Enable Register

Name: ADC_EOC_IER
Offset: 0x34
Reset: –
Property: Write-only

This register can only be written if the WPITEN bit is cleared in the ADC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
	EOC31	EOC30						
Access	W	W

Reset	–	–	–	–	–	–	–	–

Bits 30, 31 – EOC30, EOC31 End of Conversion Interrupt Enable x

Value	Description
0	No effect.
1	Enables the corresponding interrupt.

Bits 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15 – EOCx End of Conversion Interrupt Enable x

Value	Description
0	No effect.
1	Enables the corresponding interrupt.

38.6.15 ADC End Of Conversion Interrupt Disable Register

Name: ADC_EOC_IDR
Offset: 0x38
Reset: –
Property: Write-only

This register can only be written if the WPITEN bit is cleared in the ADC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
	EOC31	EOC30						
Access	W	W						
Reset	–	–

Access	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0

Bits 30, 31 – EOC30, EOC31 End of Conversion Interrupt Enable x

Value	Description
0	The corresponding analog channel is disabled, or the conversion is not finished. This flag is cleared when reading the corresponding ADC_CDRx registers.
1	The corresponding analog channel is enabled and conversion is complete.

Bits 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15 – EOCx End of Conversion x (automatically set / cleared)

Value	Description
0	The corresponding analog channel is disabled, or the conversion is not finished. This flag is cleared when reading the corresponding ADC_CDRx registers.
1	The corresponding analog channel is enabled and conversion is complete.

38.6.18 ADC Temperature Sensor Mode Register

Name: ADC_TEMPMR
Offset: 0x44
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the ADC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
			TEMPCMPMOD[1:0]					TEMPON
Access			R/W	R/W				R/W
Reset			0	0				0

Bits 5:4 – TEMPCMPMOD[1:0] Temperature Comparison Mode

Value	Name	Description
0	LOW	Generates the TEMPCHG flag in ADC_ISR when the converted data is lower than the low threshold of the window.
1	HIGH	Generates the TEMPCHG flag in ADC_ISR when the converted data is higher than the high threshold of the window.
2	IN	Generates the TEMPCHG flag in ADC_ISR when the converted data is in the comparison window.
3	OUT	Generates the TEMPCHG flag in ADC_ISR when the converted data is out of the comparison window.

Bit 0 – TEMPON Temperature Sensor On

Value	Description
0	The temperature sensor is not enabled.
1	The temperature sensor is enabled and the measurements are triggered.

38.6.19 ADC Temperature Compare Window Register

Name: ADC_TEMPCWR
Offset: 0x48
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the ADC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
					THIGHTHRES[11:8]			
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 27:16 – THIGHTHRES[11:0] Temperature High Threshold
High threshold associated to ADC_TEMPMR compare settings.

Bits 11:0 – TLOWTHRES[11:0] Temperature Low Threshold
Low threshold associated to ADC_TEMPMR compare settings.

38.6.20 ADC Overrun Status Register

Name: ADC_OVER
Offset: 0x4C
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
	OVRE31	OVRE30						
Access	W	W						
Reset	0	0						

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8

	OVRE7	OVRE6	OVRE5	OVRE4	OVRE3	OVRE2	OVRE1	OVRE0
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bits 30, 31 – OVRE30, OVRE31 Overrun Error x

Value	Description
0	No overrun error has occurred on the corresponding channel since the last read of ADC_OVER.
1	An overrun error has occurred on the corresponding channel since the last read of ADC_OVER.

Bits 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15 – OVREx Overrun Error x
An overrun error does not always mean that the unread data has been replaced by new valid data. See Enhanced Resolution Mode and Digital Averaging Function for details.

Value	Description
0	No overrun error has occurred on the corresponding channel since the last read of ADC_OVER.
1	An overrun error has occurred on the corresponding channel since the last read of ADC_OVER.

38.6.21 ADC Extended Mode Register

Name: ADC_EMR
Offset: 0x50
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the ADC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
		ALTCH	ADCMODE[1:0]			SIGNMODE[1:0]		TAG
Access		R/W	R/W	R/W		R/W	R/W	R/W
Reset		0	0	0		0	0	0

Bit	23	22	21	20	19	18	17	16
	TRACKX[1:0]		ALWAYS0	ASTE		OSR[2:0]		
Access	R/W	R/W	R/W	R/W		R/W	R/W	R/W
Reset	0	0	0	0		0	0	0

Bit	15	14	13	12	11	10	9	8
			CMPFILTER[1:0]				CMPALL	CMPSEL[4]
Access			R/W	R/W			R/W	R/W
Reset			0	0			0	0

Bit	7	6	5	4	3	2	1	0
	CMPSEL[3:0]					CMPTYPE	CMPMODE[1:0]	
Access	R/W	R/W	R/W	R/W		R/W	R/W	R/W
Reset	0	0	0	0		0	0	0

Bit 30 – ALTCH Alternate Channel Selection (Safety)

Value	Description
0	The regular channels are selected.
1	The alternate channels are selected.

Bits 29:28 – ADCMODE[1:0] ADC Running Mode

See Automatic Error Correction for details on ADC Running mode.

Value	Name	Description
0	NORMAL	Normal mode of operation.
1	OFFSET_ERROR	Offset Error mode to measure the offset error. See the table ADC Running Modes.
2	GAIN_ERROR_HIGH	Gain Error mode to measure the gain error. See the table ADC Running Modes.
3	GAIN_ERROR_LOW	Gain Error mode to measure the gain error. See the table ADC Running Modes.

Bits 26:25 – SIGNMODE[1:0] Sign Mode

If conversion results are signed and resolution is below 16 bits, the sign is extended up to bit 15 (for example, 0xF43 for 12-bit resolution is read as 0xFF43 and 0x467 is read as 0x0467). See Conversion Results Format.

Value	Name	Description
0	SE_UNSG_DF_SIGN	Single-ended channels: unsigned conversions Differential channels: signed conversions
1	SE_SIGN_DF_UNSG	Single-ended channels: signed conversions Differential channels: unsigned conversions
2	ALL_UNSIGNED	All channels: unsigned conversions
3	ALL_SIGNED	All channels: signed conversions

Bit 24 – TAG ADC_LCDR Tag

Value	Description
0	Sets ADC_LCDR.NO_OSR_CHNB/CHNBOSR to zero.
1	Appends the channel number to the conversion result in ADC_LCDR.

Bits 23:22 – TRACKX[1:0] Tracking Time x4, x8 or x16

Value	Name	Description
0	TRACKTIMx1	ADC_MR.TRACKTIM effect is multiplied by 1.
1	TRACKTIMx4	ADC_MR.TRACKTIM effect is multiplied by 4.
2	TRACKTIMx8	ADC_MR.TRACKTIM effect is multiplied by 8.
3	TRACKTIMx16	ADC_MR.TRACKTIM effect is multiplied by 16.

Bit 21 – ALWAYS0 Must always be written to 0

Bit 20 – ASTE Averaging on Single Trigger Event

Value	Name	Description
0	MULTI_TRIG_AVERAGE	The average requests several trigger events.
1	SINGLE_TRIG_AVERAGE	The average requests only one trigger event.

Bits 18:16 – OSR[2:0] Over Sampling Rate

Value	Name	Description
0	NO_AVERAGE	No averaging. ADC sample rate is maximum.
1	OSR4	1-bit enhanced resolution by averaging. ADC sample rate divided by 4.
2	OSR16	2-bit enhanced resolution by averaging. ADC sample rate divided by 16.
3	OSR64	1-bit enhanced resolution by averaging. ADC sample rate divided by 64.
4	OSR256	2-bit enhanced resolution by averaging. ADC sample rate divided by 256.

Bits 13:12 – CMPFILTER[1:0] Compare Event Filtering
Number of consecutive compare events necessary to raise the flag = CMPFILTER+1
When programmed to 0, the flag rises as soon as an event occurs.
See Comparison Window when using the filtering option (CMPFILTER > 0).

Bit 9 – CMPALL Compare All Channels

Value	Description
0	Only the channel indicated in CMPSEL is compared.
1	All channels are compared.

Bits 8:4 – CMPSEL[4:0] Comparison Selected Channel
If CMPALL = 0: CMPSEL indicates which channel has to be compared.
If CMPALL = 1: No effect.

Bit 2 – CMPTYPE Comparison Type

Value	Name	Description
0	FLAG_ONLY	Any conversion is performed and comparison function drives the COMPE flag.
1	START_CONDITION	Comparison conditions must be met to start the storage of all conversions until ADC_CR.CMPRST is set.

Bits 1:0 – CMPMODE[1:0] Comparison Mode

Value	Name	Description
0	LOW	When the converted data is lower than the low threshold of the window, generates the COMPE flag in ADC_ISR or, in Partial Wake-up mode, defines the conditions to exit the system from Wait mode.
1	HIGH	When the converted data is higher than the high threshold of the window, generates the COMPE flag in ADC_ISR or, in Partial Wake-up mode, defines the conditions to exit the system from Wait mode.
2	IN	When the converted data is in the comparison window, generates the COMPE flag in ADC_ISR or, in Partial Wake-up mode, defines the conditions to exit the system from Wait mode.

Value	Name	Description
3	OUT	When the converted data is out of the comparison window, generates the COMPE flag in ADC_ISR or, in Partial Wake-up mode, defines the conditions to exit the system from Wait mode.

38.6.22 ADC Compare Window Register

Name: ADC_CWR
Offset: 0x54
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the ADC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
	HIGHTHRES[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	HIGHTHRES[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	LOWTHRES[15:8]

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 31:16 – HIGHTHRES[15:0] High Threshold
High threshold associated to ADC_EMR compare settings.

Bits 15:0 – LOWTHRES[15:0] Low Threshold
Low threshold associated to ADC_EMR compare settings.

38.6.23 ADC Channel Configuration Register

Name: ADC_CCR
Offset: 0x5C
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the ADC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	DIFF7	DIFF6	DIFF5	DIFF4	DIFF3	DIFF2	DIFF1	DIFF0
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15 – DIFFx Differential Inputs for Channel x

Value	Description
0	Corresponding channel is set in Single-ended mode.
1	Corresponding channel is set in Differential mode.

38.6.24 ADC Channel Data Register

Name: ADC_CDRx
Offset: 0x60 + x*0x04 [x=0..31]
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
	DATA[15:8]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	DATA[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bits 15:0 – DATA[15:0] Converted Data
The analog-to-digital conversion data is placed into this register at the end of a conversion and remains until a new conversion is completed. ADC_CDRx is only loaded if the corresponding analog channel is enabled.

38.6.25 ADC Analog Control Register

Name: ADC_ACR
Offset: 0xE0
Reset: 0x00000100
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the ADC Write Protection Mode Register.

By default, bits 12 and 13 are set to 1 and 0, respectively, and must not be modified.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
								SRCLCH
Access								R/W
Reset								0

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
Access								
Reset								

Bit 16 – SRCLCH Source Last Channel

Value	Name	Description
0	VTEMP	The highest index channel is driven by the output of the temperature sensor.
1	VBG	The highest index channel is driven by the reference voltage of the temperature sensor.

38.6.26 ADC FIFO Mode Register

Name: ADC_FMR
Offset: 0xE4
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the ADC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
	FIFOCNT[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
	CHUNK[3:0]						ENLEVEL	ENFIFO
Access	R/W	R/W	R/W	R/W			R/W	R/W
Reset	0	0	0	0			0	0

Bits 23:16 – FIFOCNT[7:0] FIFO Count
Number of conversions available in the FIFO (not a source of interrupt).

Bits 7:4 – CHUNK[3:0] Chunk Size
Number of elements in FIFO required to generate a DMA request. Minimum value is 1. Maximum value is 15.

Bit 1 – ENLEVEL Enable Level

Value	Description
0	Request to DMA is generated as soon as one data is written in FIFO when FIFO is enabled. CHUNK is not used.
1	Request to DMA is generated as soon as the number of written elements in the FIFO is greater than or equal to CHUNK.

Bit 0 – ENFIFO Enable FIFO

Value	Description
0	FIFO is disabled.
1	FIFO is enabled.

38.6.27 ADC Trigger Register

Name: ADC_TRGR
Offset: 0x100
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the ADC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
	TRGPER[23:16]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	TRGPER[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	TRGPER[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
						TRGMOD[2:0]		
Access						R/W	R/W	R/W
Reset						0	0	0

Bits 31:8 – TRGPER[23:0] Trigger Period
Effective only if TRGMOD defines a periodic trigger.
Defines the periodic trigger period, with the following equation:
Trigger Period = (TRGPER + 1) / ADCCLK
The minimum time between two consecutive trigger events must be strictly greater than the duration time of the longest conversion sequence depending on the configuration of registers ADC_MR, ADC_CHSR, ADC_SEQRx and ADC_TSMR.

Bits 2:0 – TRGMOD[2:0] Trigger Mode

Value	Name	Description
0	NO_TRIGGER	No trigger, only software trigger can start conversions
1	EXT_TRIG_RISE	Rising edge of the selected trigger event, defined in ADC_MR.TRGSEL
2	EXT_TRIG_FALL	Falling edge of the selected trigger event
3	EXT_TRIG_ANY	Any edge of the selected trigger event
4		–
5	PERIOD_TRIG	ADC internal periodic trigger (see TRGPER)
6	CONTINUOUS	Continuous mode, Free Run mode

38.6.28 ADC Correction Select Register

Name: ADC_COSR
Offset: 0x104
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the ADC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
				CSEL[4:0]				
Access				R/W	R/W	R/W	R/W	R/W
Reset				0	0	0	0	0

Bits 4:0 – CSEL[4:0] Channel Correction Select
Selects the channel to be displayed in ADC_CVR.

38.6.29 ADC Correction Values Register

Name: ADC_CVR
Offset: 0x108
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the ADC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
	GAINCORR[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	GAINCORR[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	OFFSETCORR[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	OFFSETCORR[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 31:16 – GAINCORR[15:0] Gain Correction
Gain correction to apply on converted data. Only bits 0 to 13 are relevant (other bits are ignored and read as 0).

Bits 15:0 – OFFSETCORR[15:0] Offset Correction
Offset correction to apply on converted data. The offset is signed (2's complement), only bits 0 to 11 are relevant (other bits are ignored and read as 0).

38.6.30 ADC Channel Error Correction Register

Name: ADC_CECR
Offset: 0x10C
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the ADC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
	ECORR31	ECORR30						
Access	R/W	R/W						
Reset	0	0						

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
	ECORR15	ECORR14	ECORR13	ECORR12	ECORR11	ECORR10	ECORR9	ECORR8
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	ECORR7	ECORR6	ECORR5	ECORR4	ECORR3	ECORR2	ECORR1	ECORR0
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 30, 31 – ECORR30, ECORR31 Error Correction Enable for Channel x

Value	Description
0	Automatic error correction is disabled for channel x.
1	Automatic error correction is enabled for channel x.

Bits 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15 – ECORRx Error Correction Enable for Channel x

Value	Description
0	Automatic error correction is disabled for channel x.
1	Automatic error correction is enabled for channel x.

38.6.31 ADC Write Protection Mode Register

Name: ADC_WPMR
Offset: 0x118
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
	WPKEY[23:16]							
Access	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0
Bit	23	22	21	20	19	18	17	16
	WPKEY[15:8]							
Access	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8
	WPKEY[7:0]							
Access	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
						WPCREN	WPITEN	WPEN
Access						R/W	R/W	R/W
Reset						0	0	0

Bits 31:8 – WPKEY[23:0] Write Protection Key

Value	Name	Description
0x414443	PASSWD	Writing any other value in this field aborts the write operation of the WPEN and WPITEN bits. Always reads as 0.

Bit 2 – WPCREN Write Protection Control Register Enable
See Register Write Protection for the list of write-protected registers.

Value	Description
0	Disables the write protection on control registers if WPKEY corresponds to 0x414443 (“ADC” in ASCII).
1	Enables the write protection on control registers if WPKEY corresponds to 0x414443 (“ADC” in ASCII).

Bit 1 – WPITEN Write Protection Interrupt Enable
See Register Write Protection for the list of write-protected registers.

Value	Description
0	Disables the write protection on interrupt registers if WPKEY corresponds to 0x414443 (“ADC” in ASCII).
1	Enables the write protection on interrupt registers if WPKEY corresponds to 0x414443 (“ADC” in ASCII).

Bit 0 – WPEN Write Protection Enable
See Register Write Protection for the list of write-protected registers.

Value	Description
0	Disables write protection if WPKEY corresponds to 0x414443 (“ADC” in ASCII).
1	Enables write protection if WPKEY corresponds to 0x414443 (“ADC” in ASCII).

38.6.32 ADC Write Protection Status Register

Name: ADC_WPSR
Offset: 0x11C
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
	WPVSRC[15:8]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	WPVSRC[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
								WPVS
Access								R
Reset								0

Bits 23:8 – WPVSRC[15:0] Write Protection Violation Source
When WPVS = 1, WPVSRC indicates the register address offset at which a write access has been attempted.

Bit 0 – WPVS Write Protection Violation Status

Value	Description
0	No write protection violation has occurred since the last read of ADC_WPSR.
1	A write protection violation has occurred since the last read of ADC_WPSR. If this violation is an unauthorized attempt to write a protected register, the associated violation is reported into field WPVSRC.

39. Analog Comparator Controller (ACC)

39.1 Description

The Analog Comparator Controller (ACC) configures the analog comparator and generates an interrupt depending on user settings. The analog comparator embeds two 8-to-1 multiplexers that generate two internal inputs. These inputs are compared, resulting in a compare output. The hysteresis level, edge detection and polarity are configurable.

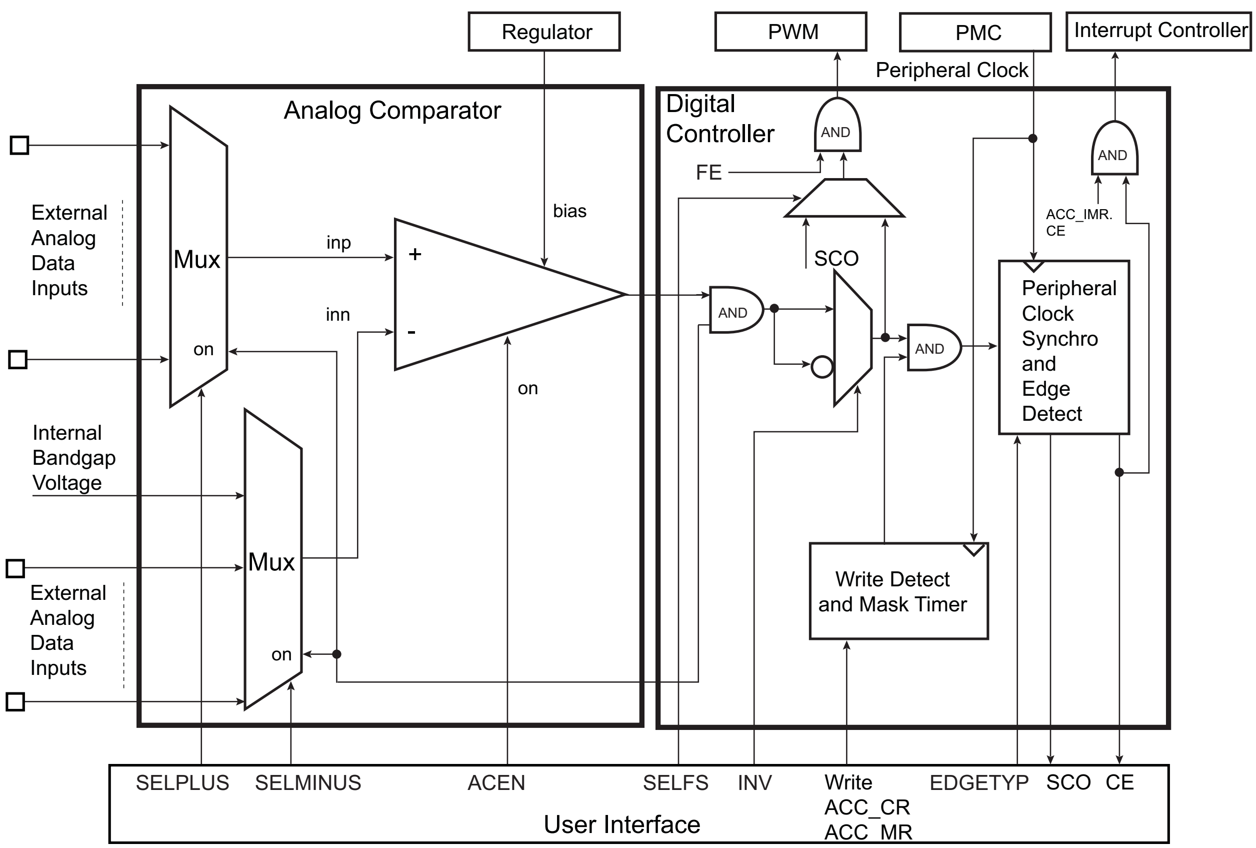
The ACC also generates a compare event which can be used by the Pulse Width Modulator (PWM).

39.2 Embedded Characteristics

- 7 User Analog Inputs Selectable for Comparison
- Bandgap Voltage Reference Selectable for Comparison
- Interrupt Generation
- Compare Event Fault Generation for PWM

39.3 Block Diagram

Figure 39-1. ACC Block Diagram



39.4 Signal Description

Table 39-1. ACC Signal Description

Pin Name	Description	Type
ACC_INP0..3, ACC_INN1..3	External analog data inputs	Input
VBG[(1)]	Internal bandgap voltage	Input

Note:
1. To enable the VBG band gap voltage (refer to the section Analog-to-Digital Converter (ADC) Controller) and enable the temperature sensor VTEMP. This also enables the VBG.

39.5 Product Dependencies

39.5.1 I/O Lines

The analog input pins (ACC_INP0..3 and ACC_INN1..3) are multiplexed with digital functions (PIO) on the IO line. By writing the SELMINUS and SELPLUS fields in the ACC Mode Register (ACC_MR), the associated IO lines are set to Analog mode.

39.5.2 Power Management

The ACC is clocked through the Power Management Controller (PMC), thus the programmer must first configure the PMC to enable the ACC clock.

Note that the voltage regulator must be activated to use the analog comparator.

39.5.3 Interrupt Sources

The ACC has an interrupt line connected to the Interrupt Controller (IC). In order to handle interrupts, the Interrupt Controller must be programmed before configuring the ACC.

39.5.4 Fault Output

The ACC has the FAULT output connected to the FAULT input of PWM. See Fault Mode and the implementation of the PWM in the product.

39.6 Functional Description

39.6.1 Description

The Analog Comparator Controller (ACC) controls the analog comparator settings and performs postprocessing of the analog comparator output.

When the analog comparator settings are modified, the output of the analog cell may be invalid. The ACC masks the output for the invalid period.

A comparison flag is triggered by an event on the output of the analog comparator and an interrupt is generated. The event on the analog comparator output can be selected among falling edge, rising edge or any edge.

The ACC registers are listed in the Register Summary.

39.6.2 Fault Mode

In Fault mode, a comparison match event is communicated by the ACC fault output which is directly and internally connected to a PWM fault input.

The source of the fault output can be configured as either a combinational value derived from the analog comparator output or as the peripheral clock resynchronized value. Refer to Block Diagram.

39.6.3 Output Masking Period

As soon as the analog comparator settings change, the output is invalid for a duration. A masking period is automatically triggered as soon as a write access is performed on the ACC_MR and ACC_CR regardless of the register data content.

The mask period is 8 × $t_{peripheral\ clock}$ if ACC_ACR.MSEL = 0.

The mask period is 128 × $t_{peripheral\ clock}$ if ACC_ACR.MSEL = 1.

The masking period is reported by reading a negative value (MASK='1') on the ACC Interrupt Status register (ACC_ISR).

39.6.4 Register Write Protection

To prevent any single software error from corrupting ACC behavior, certain registers in the address space can be write-protected by setting the WPEN bit in the ACC Write Protection Mode Register (ACC_WPMR).

If a write access to a write-protected register is detected, the WPVS flag in the ACC Write Protection Status Register is set and the field WPVSRC indicates the register in which the write access has been attempted.

The WPVS bit is automatically cleared after reading the ACC_WPSR register.

The following registers can be write-protected:

- ACC Mode Register
- ACC Analog Control Register

39.7 Register Summary

Offset	Name	Bit Pos.	7	6	5	4	3	2	1	0
0x00	ACC_CR	31:24

39.7.1 ACC Control Register

Name: ACC_CR
Offset: 0x00
Reset: –
Property: Write-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
								SWRST
Access								W
Reset								–

Bit 0 – SWRST Software Reset

Value	Description
0	No effect.
1	Resets the module.

39.7.2 ACC Mode Register

Name: ACC_MR
Offset: 0x04
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the ACC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
		FE	SELFS	INV		EDGETYP[1:0]		ACEN
Access		R/W	R/W	R/W		R/W	R/W	R/W
Reset		0	0	0		0	0	0

Bit	7	6	5	4	3	2	1	0
		SELPLUS[2:0]				SELMINUS[2:0]		
Access		R/W	R/W	R/W		R/W	R/W	R/W
Reset		0	0	0		0	0	0

Bit 14 – FE Fault Enable

Value	Name	Description
0	DIS	The FAULT output is tied to 0.
1	EN	The FAULT output is driven by the signal defined by SELFS.

Bit 13 – SELFS Selection Of Fault Source

Value	Name	Description
0	CE	The CE flag is used to drive the FAULT output.
1	OUTPUT	The output of the analog comparator flag is used to drive the FAULT output.

Bit 12 – INV Invert Comparator Output

Value	Name	Description
0	DIS	Analog comparator output is directly processed.
1	EN	Analog comparator output is inverted prior to being processed.

Bits 10:9 – EDGETYP[1:0] Edge Type

Value	Name	Description
0	RISING	Only rising edge of comparator output
1	FALLING	Falling edge of comparator output
2	ANY	Any edge of comparator output

Bit 8 – ACEN Analog Comparator Enable

Value	Name	Description
0	DIS	Analog comparator disabled.
1	EN	Analog comparator enabled.

Bits 6:4 – SELPLUS[2:0] Selection For Plus Comparator Input
0..3: Selects the input to apply on analog comparator SELPLUS comparison input.

Value	Name	Description
0	ACC_INP0	Selects ACC_INP0
1	ACC_INP1	Selects ACC_INP1
2	ACC_INP2	Selects ACC_INP2
3	ACC_INP3	Selects ACC_INP3

Bits 2:0 – SELMINUS[2:0] Selection for Minus Comparator Input
0..3: Selects the input to apply on analog comparator SELMINUS comparison input.

Value	Name	Description
0	VBG	Selects VBG
1	ACC_INN1	Selects ACC_INN1
2	ACC_INN2	Selects ACC_INN2
3	ACC_INN3	Selects ACC_INN3

39.7.3 ACC Interrupt Enable Register

Name: ACC_IER
Offset: 0x24
Reset: –
Property: Write-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access

Reset								

Bit	7	6	5	4	3	2	1	0
								CE
Access								W
Reset								–

Bit 0 – CE Comparison Edge

Value	Description
0	No effect.
1	Disables the interrupt when the selected edge (defined by EDGETYP) occurs.

39.7.5 ACC Interrupt Mask Register

Name: ACC_IMR
Offset: 0x2C
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access

Access								
Reset								

Bit	7	6	5	4	3	2	1	0
								CE
Access								R
Reset								0

Bit 0 – CE Comparison Edge

Value	Description
0	The interrupt is disabled.
1	The interrupt is enabled.

39.7.6 ACC Interrupt Status Register

Name: ACC_ISR
Offset: 0x30
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
	MASK							
Access	R							
Reset	0							

Bit	23	22	21	20	19	18	17	16
Access

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
							SCO	CE
Access							R	R
Reset							0	0

Bit 31 – MASK Flag Mask

Value	Description
0	The CE flag and SCO value are valid.
1	The CE flag and SCO value are invalid.

Bit 1 – SCO Synchronized Comparator Output
Returns an image of the analog comparator output after being preprocessed (refer to Block Diagram).
If INV = 0

- SCO = 0 if inn > inp
- SCO = 1 if inp > inn

If INV = 1

- SCO = 1 if inn > inp
- SCO = 0 if inp > inn

Bit 0 – CE Comparison Edge (cleared on read)

Value	Description
0	No edge occurred (defined by EDGETYP) on analog comparator output since the last read of ACC_ISR.
1	A selected edge (defined by EDGETYP) on analog comparator output occurred since the last read of ACC_ISR.

39.7.7 ACC Analog Control Register

Name: ACC_ACR
Offset: 0x94
Reset: 0
Property: Read/Write

This register can only be written if the WPEN bit is cleared in ACC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
								MSEL
Access								R/W
Reset								0

Bit 0 – MSEL Masking Period Selection

Value	Description
0	Masks AC output for 16 peripheral clock periods after any write access in ACC_MR or ACC_CR.
1	Masks AC output for 128 peripheral clock periods after any write access in ACC_MR or ACC_CR.

39.7.8 ACC Write Protection Mode Register

Name: ACC_WPMR
Offset: 0xE4
Reset: 0x00000000
Property: Read/Write

Refer to Register Write Protection for the list of registers that can be write-protected.

Bit	31	30	29	28	27	26	25	24
	WPKEY[23:16]							
Access	W	W	W	W	W	W	W	W

								WPEN
Access								R/W
Reset								0

Bits 31:8 – WPKEY[23:0] Write Protection Key

Value	Name	Description
0x414343	PASSWD	Writing any other value in this field aborts the write operation of the WPEN bit. Always reads as 0.

Bit 0 – WPEN Write Protection Enable

Value	Description
0	Disables the write protection if WPKEY corresponds to 0x414343 (“ACC” in ASCII).
1	Enables the write protection if WPKEY corresponds to 0x414343 (“ACC” in ASCII).

39.7.9 ACC Write Protection Status Register

Name: ACC_WPSR
Offset: 0xE8
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access

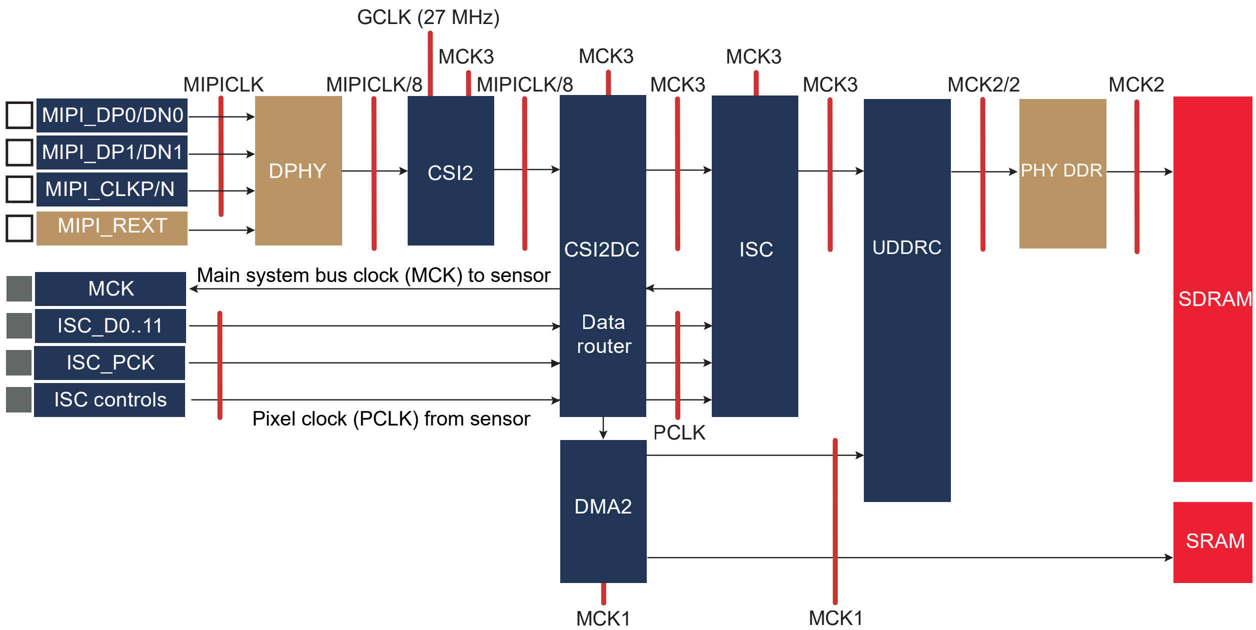
Bit 0 – WPVS Write Protection Violation Status

Value	Description
0	No write protection violation has occurred since the last command ACC_CR.SWRST=1.
1	A write protection violation (WPEN = 1) has occurred since the last command ACC_CR.SWRST=1.

40. IMAGE SUBSYSTEM

40.1 Block Diagram

Figure 40-1. Image Subsystem Block Diagram



This block diagram shows peripheral clocks used and clock frequencies on data paths.

40.2 Components

The image subsystem connects MIPI and RGB image sensors to the device and is built with:

- Image Sensor Controller (ISC)
- CSI-2 Demultiplexer Controller (CSI2DC)
- Camera Sensor Host Interface (CSI2)
- Physical interface to connect CSI-2 camera sensors (DPHY)
- Central DMA2, to store non-video metadata in memory

40.3 Product Dependencies

40.3.1 Clocks

In addition to MCK0, MCK1 and MCK2, the following clocks must be started to run the image subsystem:

- CSI2 GCLK input
- MCK3, that can be sourced from a dedicated IMGPLL

All clocks shown in the block diagram are subdivisions of these clocks.

40.3.2 Interrupts

Refer to the table Peripheral Identifiers.

40.3.3 Reset

Image peripherals are connected to the processor and peripherals reset line.

40.3.4 I/Os

MIPI I/Os are high-speed I/Os powered by VDDDPHY/GNDDPHY.

ISC I/Os are multiplexed with other peripherals and powered by VDDIOP0 or VDDIOP1.

40.3.5 Power Saving

To save power consumption, the sensor can stop the image stream. In this case, proceed as follows to enter the image subsystem in Low-power mode:

1. Disable capture in ISC:
   – ISC_CTRLDIS.DISABLE = 1 (to end capture at next vertical synchronization detection)
   – Check ISC_CTRLSR.CAPTURE = 0
2. Power down DPHY:
   – CSI –> CSI2_RESETN = 0
   – CSI –> CSI2_PHY_SHUTDOWNZ = 0
   – CSI –> CSI2_DPHY_RSTZ = 0
3. Reset CSI2DC software:
   – CSI2DC –> CSI2DC_GCTLR = 1

The image subsystem is now in Low-power mode. Proceed as follows to restart the capture:

1. Enable capture in ISC:
   – With color profile update:
     • Write all required configuration registers.
     • ISC_CTRLEN = 0x3 (CAPTURE =1 and UPPRO =1)
   – Without color profile update:
     • ISC_CTRLDIS.CAPTURE = 1
2. Release CSI2DC software reset:
   – CSI2DC –> CSI2DC_GCTLR = 0
3. Enable image pipe:
   – CSI2DC –> CSI2DC_VPER = 1
   – CSI2DC –> CSI2DC_DPER = 1
   – CSI2DC –> CSI2DC_PUR = 0x3
4. Bring DPHY out of power down:
   – CSI –> CSI2_PHY_SHUTDOWNZ = 1
   – CSI –> CSI2_DPHY_RSTZ = 1
   – CSI –> CSI2_RESETN = 1
   – Wait for LP-11 on the clock lane and activate data lanes by probing the CSI2_PHY_STOPSTATE register.

The image datapath can now start streaming frames.

40.4 Special Functions in SFR/SFRBU

None.

41. Camera Serial Interface (CSI)

41.1 Description

The Camera Serial Interface (CSI) receives data from a CSI-2-compliant camera sensor. A D-PHY configured as a client (RX) acts as the physical layer.

The CSI implements the MIPI CSI-2 protocol specification. The CSI-2 link protocol specification is a part of communication protocols defined by MIPI Alliance standards intended for mobile system chip-to-chip communications. The CSI-2 specification is for the image application processor communication in cameras.

41.2 Embedded Characteristics

The CSI is compliant with the following standards:

- MIPI Alliance Specification for Camera Serial Interface 2 (CSI-2), Version 1.2
- MIPI Alliance Specification for D-PHY, Version 1.2

D-PHY Characteristics:

- Two-lane Receive MIPI D-PHY Compliant with Revision 1.1 Specification
- Lane Operation Ranging from 80 Mbps to 1.5 Gbps in Forward Direction
- Aggregate Throughput up to 3 Gbps with Two Data Lanes
- Low-Power Escape Modes and Ultra-Low-Power State

CSI-2 Host Characteristics:

- Dynamically Configurable Multi-Lane Merging
- Long and Short Packet Decoding
- Timing Accurate Signaling of Frame and Line Synchronization Packets
- Frame Formats:
  - General frame or digital interlaced video with or without accurate sync timing
  - Data type (packet or frame level) and virtual channel interleaving
- All Primary and Secondary Data Formats.
  - YUV, RGB, RAW (for details, refer to the section Image Sensor Interface (ISC))
  - Generic 8-bit long packet data types
  - User-defined byte-based data
- Error Detection and Correction
  - PHY level
  - Packet level
  - Line level
  - Frame level
- EMI Mitigation

41.3 Signal Description

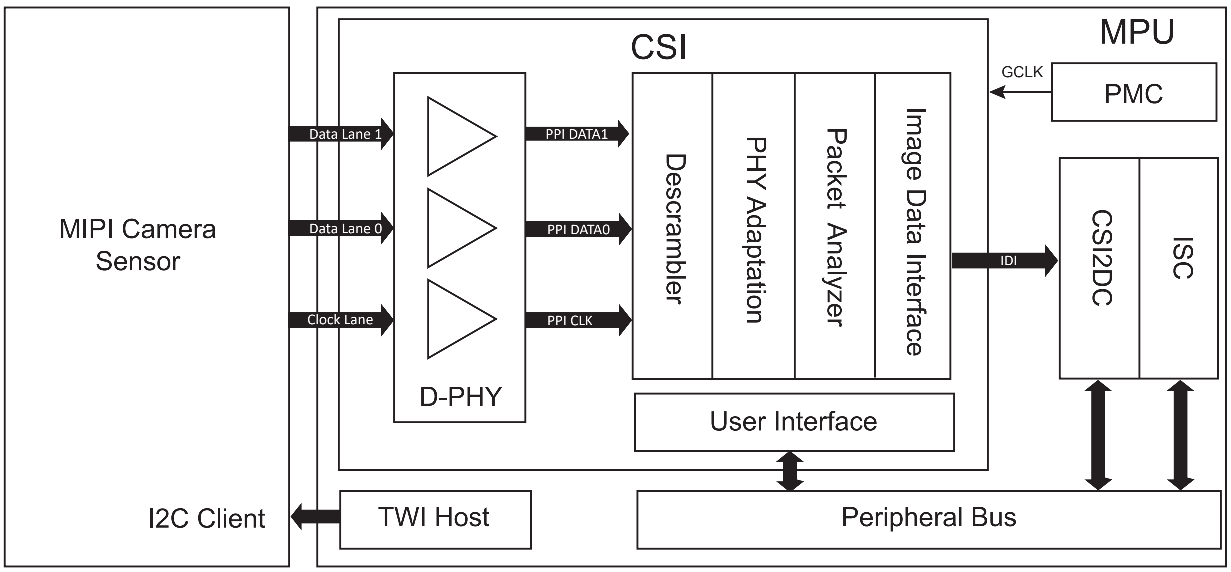
Signal Name	Type	Function
MIPI_DP0	Input	Positive D-PHY differential data line receiver, Lane 0
MIPI_DN0	Input	Negative D-PHY differential data line receiver, Lane 0
MIPI_DP1	Input	Positive D-PHY differential data line receiver, Lane 1

...........continued

Signal Name	Type	Function
MIPI_DN1	Input	Negative D-PHY differential data line receiver, Lane 1
MIPI_CLKP	Input	Positive D-PHY differential clock line receiver
MIPI_CLKN	Input	Negative D-PHY differential clock line receiver
MIPI_REXT	Input	D-PHY external resistor connection

41.4 Block Diagram

Figure 41-1. CSI Block Diagram



CSI main blocks:

- Descrambler: Converts the PHY-Protocol Interface (PPI) scrambled data to its original values.
- PHY Adaptation Layer: Manages the PHY interface, including PHY error handling.
- Packet Analyzer: Data lane merging, together with header decoding, error detection and correction, frame size error detection, and CRC error detection.
- Image Data Interface (IDI): Separates CSI-2 packet header information and reorders the data according to memory storage format. Also generates the timing accurate video synchronization signals. Several error detections are also performed at frame level and line level.
- User Interface: Registers for configuration and control, fully programmable interrupt generator, notifies and monitors the error conditions in the CSI.

Note: Refer to the sections “Image Sensor Controller (ISC)” and “CSI-2 Demultiplexer Controller (CSI2DC)” for details.

41.5 Product Dependencies

41.5.1 Power Management

The CSI is not continuously clocked. Before using it, the programmer must first enable the CSI peripheral and generic (GCLK) clocks in the Power Management Controller.

41.5.2 Interrupt Sources

The CSI interrupt line is connected to one of the internal sources of the interrupt controller. Using the CSI interrupt requires prior programming of the interrupt controller.

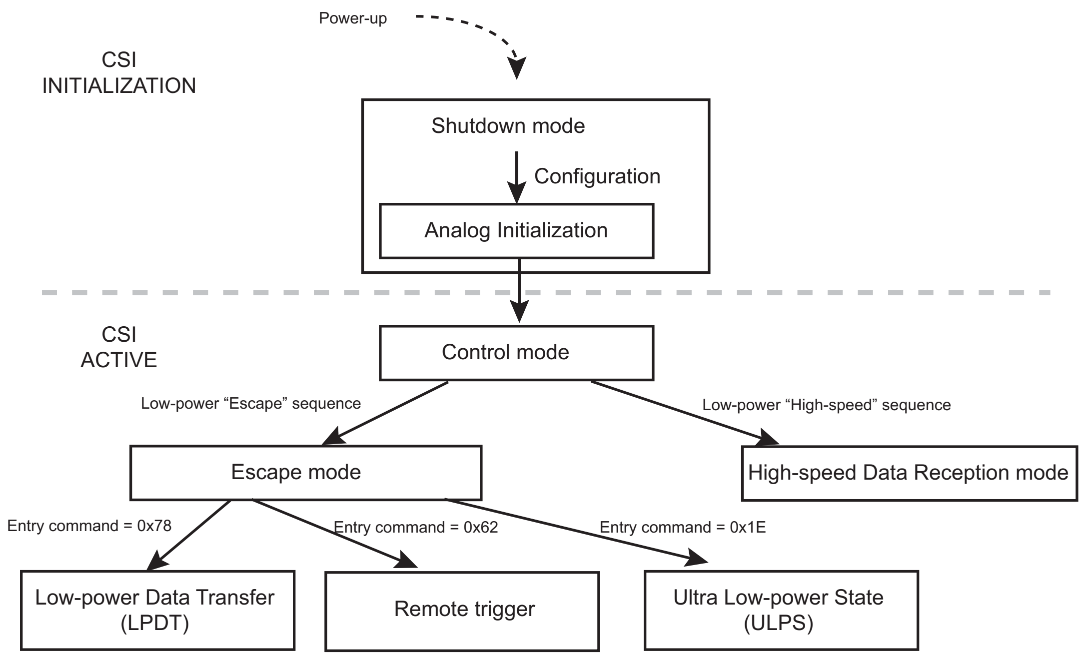
41.6 Functional Description

The CSI interfaces the Image Sensor Controller (ISC) and a MIPI CSI-2 compliant Camera Sensor.

41.6.1 D-PHY Operating Modes

The following figure illustrates the D-PHY initialization from Shutdown to Active modes.

Figure 41-2. D-PHY Initialization from Shutdown to Active Modes



41.6.1.1 Power-Up Mode

The power-up sequence is as follows:

1. Core voltage (VDDCORE) power-up
2. I/O voltage (VDDPHY) power-up

41.6.1.2 Shutdown Mode

Shutdown mode is the operating mode with the lowest power consumption. All analog blocks are disabled, and digital logic is reset. To enter this mode, write to ‘0’ the bits DPHY_RSTZ in the PHY Reset register (CSI_DPHY_RSTZ) and DPHY_SHUTDOWNZ in the PHY Shutdown register (CSI_DPHY_SHUTDOWNZ).

In Shutdown mode, the differential lines of MIPI_DNx/Px and MIPI_CLKN/P are high impedance (Hi-Z).

By default, the D-PHY is configured to work only on the lower operating range of 80-110 Mbps. If higher bit rate operation is required, the register hsfreqrange (HS RX Control of Lane 0) must be set with the proper code. If the D-PHY is expected to change the bit rate after initialization, hsfreqrange should be updated while in Control mode.

When CSI_DPHY_RSTZ.DPHY_RSTZ and CSI_DPHY_SHUTDOWNZ.DPHY_SHUTDOWNZ are set to ‘1’, the D-PHY exits Shutdown mode and starts an initialization procedure.

41.6.1.3 Analog Initialization

The D-PHY comprises 2 data lanes, but some applications may require only one. The number of lanes is configured in the Lane Configuration register (CSI_N_LANES) and must be done only when the D-PHY is in Shutdown mode.

Before starting normal operation, a D-PHY bit rate code must be configured as shown in the following table. Follow the steps listed below for configuration:

1. Ensure that the D-PHY is in Shutdown mode. See Shutdown Mode.
2. Reset the analog configuration by generating a high pulse on CSI_DPHY_TEST_CTRL0. DPHY_TESTCLR.
3. Write a ‘1’ to CSI_DPHY_TEST_CTRL0.DPHY_TESTCLK.
4. Write 0x44 to CSI_DPHY_TEST_CTRL1.DPHY_TESTDIN and write a ‘1’ to CSI_DPHY_TEST_CTRL1.DPHY_TESTEN.
5. Write a ‘0’ to CSI_DPHY_TEST_CTRL0.DPHY_TESTCLK to create a falling edge on DPHY_TESTCLK.
6. Write a ‘0’ to CSI_DPHY_TEST_CTRL1.DPHY_TESTEN and write the configuration value from the following table to CSI_DPHY_TEST_CTRL1.DPHY_TESTDIN.
7. Write a high pulse to CSI_DPHY_TEST_CTRL0.DPHY_TESTCLK by writing ‘1’ immediately followed by ‘0’.

Table 41-1. Bit Rate Ranges

Range (Mbps)	High-Speed Bit Rate Code
80-89	000000
90-99	010000
100-109	100000
110-129	000001
130-139	010001
140-149	100001
150-169	000010
170-179	010010
180-199	100010
200-219	000011
220-239	010011
240-249	100011
250-269	000100
270-299	010100
300-329	000101
330-359	010101
360-399	100101
400-449	000110
450-499	010110
500-549	000111
550-599	010111
600-649	001000
650-699	011000
700-749	001001
750-799	011001
800-849	101001
850-899	111001
900-949	001010

...........continued

Range (Mbps)	High-Speed Bit Rate Code
950-999	011010
1000-1049	101010
1050-1099	111010
1100-1149	001011
1150-1199	011011
1200-1249	101011
1250-1299	111011
1300-1349	001100
1350-1399	011100
1400-1449	101100
1450-1500	111100

The initialization period is a protocol-dependent parameter with a minimum of 100 µs defined by the specification. The D-PHY starts decoding the low-power commands after the analog initialization.

41.6.1.4 Active Modes

41.6.1.4.1 Control Mode

Control mode is the default operating mode. After initialization is completed (analog calibrations), the D-PHY remains in this default mode until a request is placed. The request is placed directly through the sequence of low-power signals in the lanes. The receiver remains in Control mode while receiving Low-power (LP) Stop state (LP-11) in the lines (see the following figure).

Following a request, a lane can exit Control mode for High-speed Data Transfer mode or Escape mode.

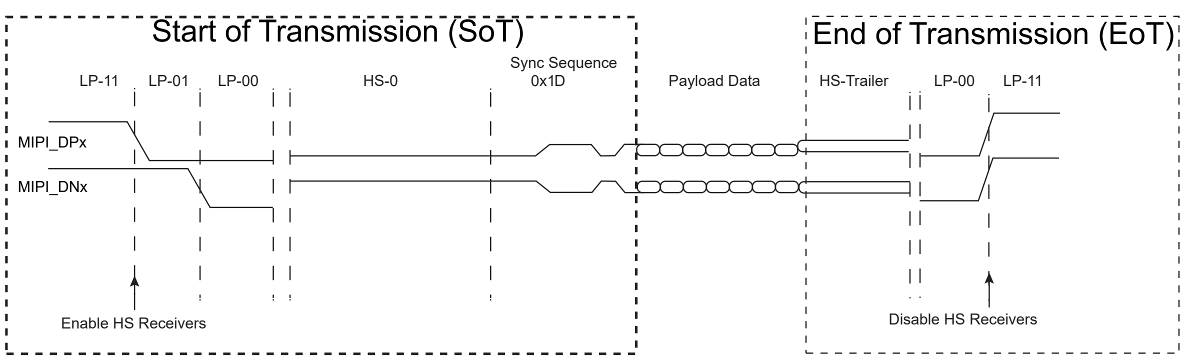
41.6.1.4.2 High-Speed Data Reception Mode

High-speed data reception occurs in bursts. Only during these bursts is the lane in High-Speed mode. A high-speed burst must start from and return to a Stop state (Control mode).

Each data lane can receive a high-speed transmission independently of the state of the remaining data lanes.

A burst contains the low-power initialization sequence, the high-speed data payload, and the end-of-transmission sequence.

Figure 41-3. HS Data Reception Sequence



The D-PHY receiver enters High-Speed mode following the sequence of low-power states in the lines LP-11, LP-01, and LP-00. This sequence is seen as a High-Speed mode request, and toggles the enabling of the high-speed receivers. Synchronization is then achieved through the identification of the leader sequence in the received differential high-speed data. Once the synchronization is achieved, the D-PHY outputs the received bytes through the protocol layer, until a Stop state (LP-11) is detected in the lane.

41.6.1.4.3 Escape Mode

Escape mode is a special mode of operation that uses the data lanes to communicate asynchronously using the low-power states at low speed. A data lane enters Escape mode through an Escape mode entry procedure (LP-11, LP-10, LP-00, LP-01, LP-00). If an LP-11 is detected before reaching LP-00 state, the entry is aborted and the receiver returns to the Stop state. Once the sequence is correctly completed, the transmitter sends an 8-bit command to indicate a requested action. The table below shows the actions supported by Escape mode. If the entry command is invalid, the MAIN_DPHY_ERRESC_x error flag goes high, and the receiver waits until the transmitter returns to the Stop state.

Table 41-2. Possible Escape Mode Sequences for Data Lanes

Escape Mode Action	Entry Command Pattern (First Bit to Last Bit to be Transmitted)	Command Type
Ultra-Low-Power State	0x1E	mode
Reset Trigger	0x62	trigger
Low-Power Data Transmission	0x87	mode

Low-Power Data Transmission (LPDT)

In LPDT mode, the data can be received on the lines at low speed in Low-Power mode. High-speed receivers are off and low-power receivers are on. During LPDT, the protocol can pause by maintaining a Space state on the lines.

Remote Trigger

Remote Trigger mode allows the protocol to send a flag to the receiving side at the request of the transmitting side.

In Escape mode, the RXCLKESC can stop at anytime in either Low or High state.

Ultra-Low-Power State (ULPS)

Ultra-Low-Power State (ULPS) mode has the lowest power consumption, excluding the Shutdown mode.

For data lanes, this mode is entered by sending an ULPS entry command, after the Escape mode entry command. During this mode, the lines are in the Space state (LP-00). Although the clock lane does not support regular Escape mode, the clock lane supports ULPS.

41.6.2 Supported Resolutions and Frame Rates

The table below presents some predefined and supported camera settings, assuming the following:

- D-PHY: clock lane frequency is in the range of 250 MHz to 750 MHz, which results in a bandwidth of 500 Mbps to 1.5 Gbps for each data lane.
- No significant control/reserved traffic is present on the link when pixel data is being transmitted.

Table 41-3. Examples of Supported Resolutions and Frame Rates

	Number of Pixels with Overhead	Refresh Rate (Hz)	Color Depth (bpp)	CSI-2 Bandwidth (Mbits)	D-PHY at 500 Mbps Number of Lanes	D-PHY at 1 Gbps Number of Lanes	D-PHY at 1.5 Gbps Number of Lanes
Camera Formats							
2 Mpixels	2560000	15	24	922	2	1	1
3 Mpixels	3840000	15	24	1382	–	2	1
5 Mpixels	6400000	15	24	2304	–	–	2
8 Mpixels	10240000	10	24	2458	–	–	2
Video Formats							

...........continued

	Number of Pixels with Overhead	Refresh Rate (Hz)	Color Depth (bpp)	CSI-2 Bandwidth (Mbits)	D-PHY at 500 Mbps Number of Lanes	D-PHY at 1 Gbps Number of Lanes	D-PHY at 1.5 Gbps Number of Lanes
1280x720 pixels (720p)	921600	30	24	664	2	1	1
1280x720 pixels (720p)	921600	60	24	1327	3	2	1

Note: The CSI does not perform data decompression. For example, if a camera transmits the compressed data according to the Annex E of the CSI-2 Specification (data compression for raw data types), the CSI decodes the data as normal non-compressed raw data. The decompression is performed by the CSI2DC block.

41.6.3 Descrambler

Data scrambling is used to mitigate the effects of EMI and RF self-interference. The data that is being transmitted is scrambled with a Pseudo-Random Binary Sequence.

The pseudo-random binary sequence can be different on each lane by configuring the Lane 0/1 Scrambling Seed registers (CSI_SCRAMBLING_SEED1/2). The default seed values after reset of the controller are given in the table below.

Lane	Initial Seed Value
0	0x1008
1	0x1188

The descrambler is enabled using the bit SCRAMBLE_ENABLE in the Descrambler Configuration register (CSI_SCRAMBLING).

Selecting the seed used by the descrambler block is done in the registers CSI_SCRAMBLING_SEED1 and CSI_SCRAMBLING_SEED2.

41.6.4 Interrupts

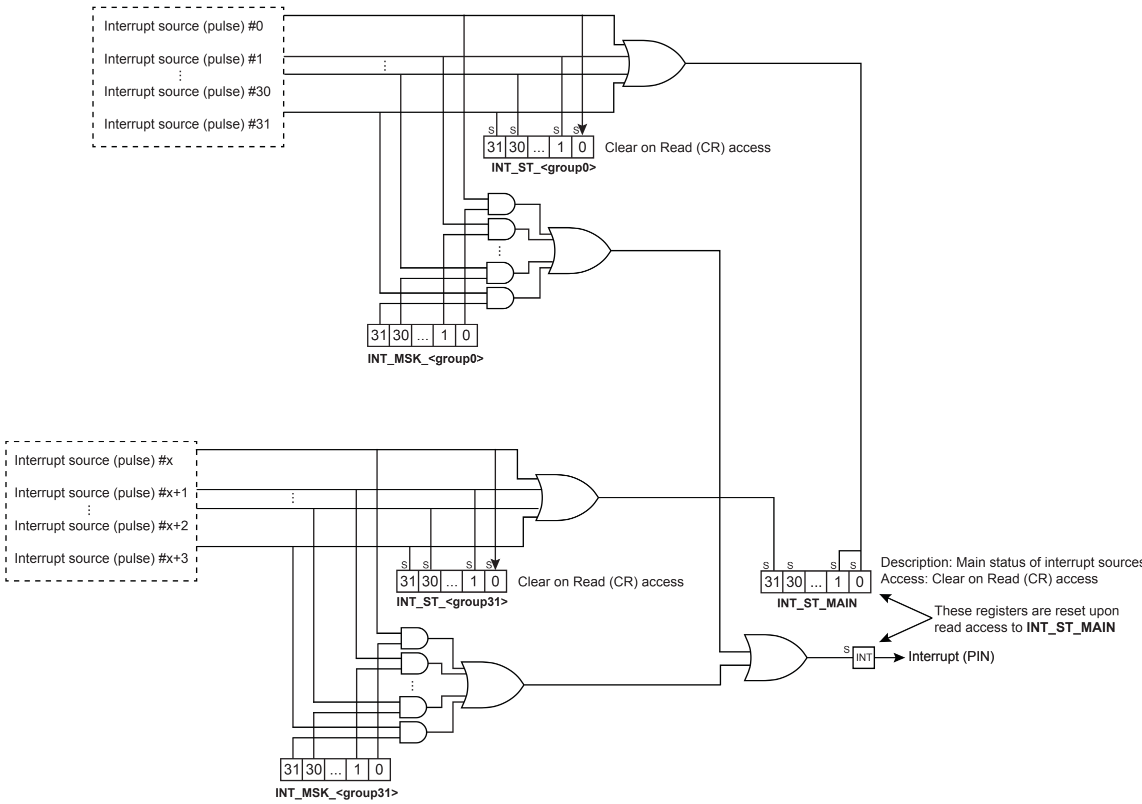
The Interrupt Status registers report error conditions.

The triggering of the CSI interrupt line can be masked by programming the Interrupt Mask registers. By default, all errors are masked. When any bit of these registers is set to 1, it enables the interrupt for a specific error.

The Interrupt Status registers are cleared on read.

The figure below shows the main parts of the interrupt mechanism.

Figure 41-4. Interrupt Mechanism



41.6.5 Error Detection

The CSI analyzes the received packets and determines if there are protocol errors. The following errors are monitored:

- Frame errors, such as incorrect frame sequence, reception of a CRC error in the most recent frame, and the mismatch between Frame Start and Frame End
- Line errors, such as incorrect line sequence and mismatch between Line Start and Line End
- Packet errors, such as payload CRC and ECC (D-PHY)
- D-PHY errors, such as synchronization pattern mismatch

41.7.1 CSI Lane Configuration Register

Name: CSI_N_LANES
Offset: 0x4
Reset: 0x00000001
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
						N_LANES[2:0]		
Access						R/W	R/W	R/W
Reset						0	0	1

Bits 2:0 – N_LANES[2:0] Number of active data lanes
The update can be performed only when the D-PHY is in Stop state.

Value	Description
000	One data lane
001	Two data lanes
010	Reserved
011	Reserved
100	Reserved
101	Reserved
110	Reserved
111	Reserved

41.7.2 CSI Reset Control Register

Name: CSI_CSI2_RESETN
Offset: 0x8
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
								CSI2_RESETN
Access								R/W
Reset								0

Bit 0 – CSI2_RESETN Internal controller logic reset

Value	Description
0	Resets the internal controller logic.
1	CSI exits Reset state.

41.7.3 CSI Main Interrupt Status Register

Name: CSI_INT_ST_MAIN
Offset: 0xC
Reset: 0x00000000
Property: Read-only

The following configuration values are valid for all listed bit names of this register:

0: No event occurred since the last read of the register.

1: An event occurred since the last read of the register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
						STATUS_INT_LINE	STATUS_INT_PKT	STATUS_INT_DPHY
Access						R	R	R
Reset						0	0	0

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
						STATUS_INT_FRAME_FATAL	STATUS_INT_PKT_FATAL	STATUS_INT_DPHY_FATAL
Access						R	R	R
Reset						0	0	0

Bit 18 – STATUS_INT_LINE
Indicates if an event occurred in the CSI_INT_ST_LINE register (cleared on read)

Bit 17 – STATUS_INT_PKT
Indicates if an event occurred in the CSI_INT_ST_PKT register (cleared on read)

Bit 16 – STATUS_INT_DPHY
Indicates if an event occurred in the CSI_INT_ST_DPHY register (cleared on read)

Bit 2 – STATUS_INT_FRAME_FATAL
Indicates if an event occurred in the CSI_INT_ST_FRAME_FATAL register (cleared on read)

Bit 1 – STATUS_INT_PKT_FATAL
Indicates if an event occurred in the CSI_INT_ST_PKT_FATAL register (cleared on read)

Bit 0 – STATUS_INT_DPHY_FATAL
Indicates if an event occurred in the CSI_INT_ST_DPHY_FATAL register (cleared on read)

41.7.4 CSI Data Identifier Register 1

Name: CSI_DATA_IDS_1
Offset: 0x10
Reset: 0x00000000
Property: Read/Write

Programs the data IDs for matching line error reporting.

Configures Data ID definition for four data types and virtual channel identifiers.

Bit	31	30	29	28	27	26	25	24
	DI3_VC[1:0]		DI3_DT[5:0]					
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	DI2_VC[1:0]		DI2_DT[5:0]					
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	DI1_VC[1:0]		DI1_DT[5:0]					
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	DI0_VC[1:0]		DI0_DT[5:0]					
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 31:30 – DI3_VC[1:0] Virtual channel for programmed data ID 3.

Bits 29:24 – DI3_DT[5:0] Data type for programmed data ID 3.

Bits 23:22 – DI2_VC[1:0] Virtual channel for programmed data ID 2.

Bits 21:16 – DI2_DT[5:0] Data type for programmed Data ID 2.

Bits 15:14 – DI1_VC[1:0] Virtual channel for programmed data ID 1.

Bits 13:8 – DI1_DT[5:0] Data type for programmed data ID 1.

Bits 7:6 – DI0_VC[1:0] Virtual channel for programmed data ID 0.

Bits 5:0 – DI0_DT[5:0] Data type for programmed data ID 0.

41.7.5 CSI Data Identifier Register 2

Name: CSI_DATA_IDS_2
Offset: 0x14
Reset: 0x00000000
Property: Read/Write

Programs the data IDs for matching line error reporting.

Configures Data ID definition for four data types and virtual channel identifiers.

Bit	31	30	29	28	27	26	25	24
	DI7_VC[1:0]		DI7_DT[5:0]					
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	DI6_VC[1:0]		DI6_DT[5:0]					
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	DI5_VC[1:0]		DI5_DT[5:0]					
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	DI4_VC[1:0]		DI4_DT[5:0]					
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 31:30 – DI7_VC[1:0] Virtual channel for programmed data ID 7

Bits 29:24 – DI7_DT[5:0] Data type for programmed data ID 7

Bits 23:22 – DI6_VC[1:0] Virtual channel for programmed data ID 6

Bits 21:16 – DI6_DT[5:0] Data type for programmed data ID 6

Bits 15:14 – DI5_VC[1:0] Virtual channel for programmed data ID 5

Bits 13:8 – DI5_DT[5:0] Data type for programmed data ID 5

Bits 7:6 – DI4_VC[1:0] Virtual channel for programmed data ID 4

Bits 5:0 – DI4_DT[5:0] Data type for programmed data ID 4

41.7.6 CSI D-PHY Shutdown Register

Name: CSI_DPHY_SHUTDOWNZ
Offset: 0x40
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
								DPHY_SHUTDOWNZ
Access								R/W
Reset								0

Bit 0 – DPHY_SHUTDOWNZ Shutdown input

Value	Description
0	Puts the D-PHY in Shutdown mode. All analog blocks are in Power-down mode and digital logic is cleared.
1	Exits from Shutdown mode.

41.7.7 CSI D-PHY Reset Register

Name: CSI_DPHY_RSTZ
Offset: 0x44
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
								DPHY_RSTZ
Access								R/W
Reset								0

Bit 0 – DPHY_RSTZ D-PHY reset control

Value	Description
0	Resets the D-PHY.
1	D-PHY exits Reset state.

41.7.8 CSI D-PHY Receive Status Register

Name: CSI_DPHY_RX
Offset: 0x48
Reset: 0x00010000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
							DPHY_RXCLK ACTIVEHS	DPHY_RXULP SCLKNOT
Access							R	R
Reset							0	1

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
							DPHY_RXULP SESC_1	DPHY_RXULP SESC_0
Access							R	R
Reset							0	0

Bit 17 – DPHY_RXCLKACTIVEHS Active high. Indicates that D-PHY clock lane is actively receiving a DDR clock.

Bit 16 – DPHY_RXULPSCLKNOT Active low. Indicates that D-PHY Clock Lane module has entered the Ultra-Low-Power state.

Bit 1 – DPHY_RXULPSESC_1 Active high. Lane module 1 has entered Ultra-Low-Power mode

Bit 0 – DPHY_RXULPSESC_0 Active high. Lane module 0 has entered Ultra-Low-Power mode

41.7.9 CSI D-PHY Stop State Register

Name: CSI_DPHY_STOPSTATE
Offset: 0x4C
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								
Bit	**23**	**22**	**21**	**20**	**19**	**18**	**17**	**16**
								DPHY_STOPSTATECLK
Access								R
Reset								0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**
Access								
Reset								
Bit	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
							DPHY_STOPSTATEDATA_1	DPHY_STOPSTATEDATA_0
Access							R	R
Reset							0	0

Bit 16 – DPHY_STOPSTATECLK Active high. D-PHY Clock lane in Stop state

Bit 1 – DPHY_STOPSTATEDATA_1 Active high. Data lane 1 in Stop state

Bit 0 – DPHY_STOPSTATEDATA_0 Active high. Data lane 0 in Stop state

41.7.10 CSI D-PHY Analog Configuration Control Register

Name: CSI_DPHY_TEST_CTRL0
Offset: 0x50
Reset: 0x00000001
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
							DPHY_TESTCLK	DPHY_TESTCLR
Access							R/W	R/W
Reset							0	1

Bit 1 – DPHY_TESTCLK Analog configuration control clock

Value	Description
0	No effect.
1	Captures the DPHY_TEST_CTRL1.DPHY_TESTDIN value. **Note:** The data is loaded on one edge of DPHY_TESTCLK, thus it is mandatory to write a '0' immediately after writing a '1'. Refer to DPHY_TEST_CTRL1.DPHY_TESTDEN.

Bit 0 – DPHY_TESTCLR Analog configuration clear

Value	Description
0	No effect.
1	Resets the analog configuration. **Note:** The reset is performed on the rising edge of DPHY_TESTCLR, thus it is mandatory to write a '0' immediately after writing a '1'.

41.7.11 CSI D-PHY Analog Configuration Data Register

Name: CSI_DPHY_TEST_CTRL1
Offset: 0x54
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
								DPHY_TESTEN
Access								R/W
Reset								0

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
	DPHY_TESTDIN[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit 16 – DPHY_TESTEN Analog configuration code selection

Value	Description
0	Transmits the high-speed bit rate code on the rising edge of CSI_DPHY_TEST_CTRL0.DPHY_TESTCLK.
1	Transmits the address (0x44) of the high-speed bit rate code on the falling edge of CSI_DPHY_TEST_CTRL0.DPHY_TESTCLK.

Bits 7:0 – DPHY_TESTDIN[7:0] Data bus carrying the value selected by DPHY_TESTEN.

41.7.12 CSI D-PHY Calibration Status Register

Name: CSI_DPHY_CAL
Offset: 0xCC
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
								RXSKEWCALHS
Access								R
Reset								0

Bit 0 – RXSKEWCALHS A low-to-high transition on this bit means that the D-PHY has initiated the calibration. (cleared on read)

41.7.13 CSI D-PHY Fatal Error Interrupt Status Register

Name: CSI_INT_ST_DPHY_FATAL
Offset: 0xE0
Reset: 0x00000000
Property: Read-only

Interrupt sources related to loss of synchronization in the D-PHY. Packet discarded.

Reading CSI_INT_ST_DPHY_FATAL register does not clear the interrupt pin.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
							DPHY_ERRSOTSYNCHS_1	DPHY_ERRSOTSYNCHS_0
Access							R	R
Reset							0	0

Bit 1 – DPHY_ERRSOTSYNCHS_1 Start of transmission error on data lane 1 (no synchronization achieved) (cleared on read)

Value	Description
0	No transmission error has occurred on data lane 1 since the last read of CSI_INT_ST_DPHY_FATAL.
1	Transmission error has occurred on data lane 1 since the last read of CSI_INT_ST_DPHY_FATAL.

Bit 0 – DPHY_ERRSOTSYNCHS_0 Start of transmission error on data lane 0 (no synchronization achieved) (cleared on read)

Value	Description
0	No transmission error has occurred on data lane 0 since the last read of CSI_INT_ST_DPHY_FATAL.
1	Transmission error has occurred on data lane 0 since the last read of CSI_INT_ST_DPHY_FATAL.

41.7.14 CSI D-PHY Fatal Error Interrupt Mask Register

Name: CSI_INT_MSK_DPHY_FATAL
Offset: 0xE4
Reset: 0x00000000
Property: Read/Write

The following configuration values are valid for all listed bit names of this register:

0: The corresponding interrupt is not enabled.

1: The corresponding interrupt is enabled.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
							MASK_DPHY_ERRSOTSYNCHS_1	MASK_DPHY_ERRSOTSYNCHS_0
Access							R/W	R/W
Reset							0	0

Bit 1 – MASK_DPHY_ERRSOTSYNCHS_1 Mask for DPHY_ERRSOTSYNCHS_1

Bit 0 – MASK_DPHY_ERRSOTSYNCHS_0 Mask for DPHY_ERRSOTSYNCHS_0

41.7.15 CSI Packet Fatal Error Interrupt Status Register

Name: CSI_INT_ST_PKT_FATAL
Offset: 0xF0
Reset: 0x00000000
Property: Read-only

Notifies which interrupt bit has caused the interruption.

Reading CSI_INT_ST_PKT_FATAL does not clear the interrupt pin.

The following configuration values are valid for all listed bit names of this register:

0: No event occurred since the last read of the register.

1: An event occurred since the last read of the register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
								ERR_ECC_DOUBLE
Access								R
Reset								0

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
					VC3_ERR_CRC	VC2_ERR_CRC	VC1_ERR_CRC	VC0_ERR_CRC
Access					R	R	R	R
Reset					0	0	0	0

Bit 16 – ERR_ECC_DOUBLE D-PHY mode: Header ECC contains at least 2 errors, unrecoverable. (cleared on read)
C-PHY mode: Header CRC unrecoverable.

Bit 3 – VC3_ERR_CRC Payload Checksum error detected on virtual channel 3 (cleared on read)

Bit 2 – VC2_ERR_CRC Payload Checksum error detected on virtual channel 2 (cleared on read)

Bit 1 – VC1_ERR_CRC Payload Checksum error detected on virtual channel 1 (cleared on read)

Bit 0 – VC0_ERR_CRC Payload Checksum error detected on virtual channel 0 (cleared on read)

41.7.16 CSI Packet Fatal Error Interrupt Mask Register

Name: CSI_INT_MSK_PKT_FATAL
Offset: 0xF4
Reset: 0x00000000
Property: Read/Write

Interrupt mask for CSI_INT_ST_PKT_FATAL controls which interrupt status bits trigger the interrupt pin.

The following configuration values are valid for all listed bit names of this register:

0: The corresponding interrupt is not enabled.

1: The corresponding interrupt is enabled.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
								MASK_ERR_ECC_DOUBLE
Access								R/W
Reset								0

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
					MASK_VC3_ERR_CRC	MASK_VC2_ERR_CRC	MASK_VC1_ERR_CRC	MASK_VC0_ERR_CRC
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bit 16 – MASK_ERR_ECC_DOUBLE Mask for ERR_ECC_DOUBLE

Bit 3 – MASK_VC3_ERR_CRC Mask for VC3_ERR_CRC

Bit 2 – MASK_VC2_ERR_CRC Mask for VC2_ERR_CRC

Bit 1 – MASK_VC1_ERR_CRC Mask for VC1_ERR_CRC

Bit 0 – MASK_VC0_ERR_CRC Mask for VC0_ERR_CRC

41.7.17 CSI Frame Error Interrupt Status Register

Name: CSI_INT_ST_FRAME_FATAL
Offset: 0x100
Reset: 0x00000000
Property: Read-only

Interrupt sources related to Frame construction. Packet discarded.

Reading CSI_INT_ST_FRAME_FATAL does not clear the interrupt pin.

The following configuration values are valid for all listed bit names of this register:

0: No event occurred since the last read of the register.

1: An event occurred since the last read of the register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
					ERR_FRAME_DATA_VC3	ERR_FRAME_DATA_VC2	ERR_FRAME_DATA_VC1	ERR_FRAME_DATA_VC0
Access					R	R	R	R
Reset					0	0	0	0

Bit	15	14	13	12	11	10	9	8
					ERR_F_SEQ_VC3	ERR_F_SEQ_VC2	ERR_F_SEQ_VC1	ERR_F_SEQ_VC0
Access					R	R	R	R
Reset					0	0	0	0

Bit	7	6	5	4	3	2	1	0
					ERR_F_BNDRY_MATCH_VC3	ERR_F_BNDRY_MATCH_VC2	ERR_F_BNDRY_MATCH_VC1	ERR_F_BNDRY_MATCH_VC0
Access					R	R	R	R
Reset					0	0	0	0

Bit 19 – ERR_FRAME_DATA_VC3 Last received Frame in virtual channel 3, had at least one CRC error (cleared on read)

Bit 18 – ERR_FRAME_DATA_VC2 Last received Frame in virtual channel 2, had at least one CRC error (cleared on read)

Bit 17 – ERR_FRAME_DATA_VC1 Last received Frame in virtual channel 1, had at least one CRC error (cleared on read)

Bit 16 – ERR_FRAME_DATA_VC0 Last received Frame in virtual channel 0, had at least one CRC error (cleared on read)

Bit 11 – ERR_F_SEQ_VC3 Incorrect Frame sequence detected in virtual channel 3 (cleared on read)

Bit 10 – ERR_F_SEQ_VC2 Incorrect Frame sequence detected in virtual channel 2 (cleared on read)

Bit 9 – ERR_F_SEQ_VC1 Incorrect Frame sequence detected in virtual channel 1 (cleared on read)

Bit 8 – ERR_F_SEQ_VC0 Incorrect Frame sequence detected in virtual channel 0 (cleared on read)

Bit 3 – ERR_F_BNDRY_MATCH_VC3 Error matching Frame Start with Frame End for virtual channel 3 (cleared on read)

Bit 2 – ERR_F_BNDRY_MATCH_VC2 Error matching Frame Start with Frame End for virtual channel 2 (cleared on read)

Bit 1 – ERR_F_BNDRY_MATCH_VC1 Error matching Frame Start with Frame End for virtual channel 1 (cleared on read)

Bit 0 – ERR_F_BNDRY_MATCH_VC0 Error matching Frame Start with Frame End for virtual channel 0 (cleared on read)

41.7.18 CSI Frame Error Interrupt Mask Register

Name: CSI_INT_MSK_FRAME_FATAL
Offset: 0x104
Reset: 0x00000000
Property: Read/Write

The following configuration values are valid for all listed bit names of this register:

0: The corresponding interrupt is not enabled.

1: The corresponding interrupt is enabled.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
					MASK_ERR_FRAME_DATA_VC3	MASK_ERR_FRAME_DATA_VC2	MASK_ERR_FRAME_DATA_VC1	MASK_ERR_FRAME_DATA_VC0
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bit 19 – MASK_ERR_FRAME_DATA_VC3 Mask for ERR_FRAME_DATA_VC3

Bit 18 – MASK_ERR_FRAME_DATA_VC2 Mask for ERR_FRAME_DATA_VC2

Bit 17 – MASK_ERR_FRAME_DATA_VC1 Mask for ERR_FRAME_DATA_VC1

Bit 16 – MASK_ERR_FRAME_DATA_VC0 Mask for ERR_FRAME_DATA_VC0

Bit 11 – MASK_ERR_F_SEQ_VC3 Mask for ERR_F_SEQ_VC3

Bit 10 – MASK_ERR_F_SEQ_VC2 Mask for ERR_F_SEQ_VC2

Bit 9 – MASK_ERR_F_SEQ_VC1 Mask for ERR_F_SEQ_VC1

Bit 8 – MASK_ERR_F_SEQ_VC0 Mask for ERR_F_SEQ_VC0

Bit 3 – MASK_ERR_F_BNDRY_MATCH_VC3 Mask for ERR_F_BNDRY_MATCH_VC3

Bit 2 – MASK_ERR_F_BNDRY_MATCH_VC2 Mask for ERR_F_BNDRY_MATCH_VC2

Bit 1 – MASK_ERR_F_BNDRY_MATCH_VC1 Mask for ERR_F_BNDRY_MATCH_VC1

Bit 0 – MASK_ERR_F_BNDRY_MATCH_VC0 Mask for ERR_F_BNDRY_MATCH_VC0

41.7.19 CSI D-PHY Interrupt Status Register

Name: CSI_INT_ST_DPHY
Offset: 0x110
Reset: 0x00000000
Property: Read-only

Interrupt caused by the D-PHY.

Reading CSI_INT_ST_DPHY does not clear the interrupt pin.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
							DPHY_ERRESC_1	DPHY_ERRESC_0
Access							R	R
Reset							0	0

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
							DPHY_ERRSOTHS_1	DPHY_ERRSOTHS_0
Access							R	R
Reset							0	0

Bit 17 – DPHY_ERRESC_1 Start of transmission error on data lane 1 (no synchronization achieved) (cleared on read)

Value	Description
0	No transmission error has occurred on data lane 1 since the last read of CSI_INT_ST_DPHY.
1	Transmission error has occurred on data lane 1 since the last read of CSI_INT_ST_DPHY.

Bit 16 – DPHY_ERRESC_0 Start of transmission error on data lane 0 (no synchronization achieved) (cleared on read)

Value	Description
0	No transmission error has occurred on data lane 0 since the last read of CSI_INT_ST_DPHY.
1	Transmission error has occurred on data lane 0 since the last read of CSI_INT_ST_DPHY.

Bit 1 – DPHY_ERRSOTHS_1 Start of transmission error on data lane 1 (synchronization can still be achieved) (cleared on read)

Value	Description
0	No transmission error has occurred on data lane 1 since the last read of CSI_INT_ST_DPHY.
1	Transmission error has occurred on data lane 1 since the last read of CSI_INT_ST_DPHY.

Bit 0 – DPHY_ERRSOTHS_0 Start of transmission error on data lane 0 (synchronization can still be achieved) (cleared on read)

Value	Description
0	No transmission error has occurred on data lane 0 since the last read of CSI_INT_ST_DPHY.
1	Transmission error has occurred on data lane 0 since the last read of CSI_INT_ST_DPHY.

41.7.20 CSI D-PHY Interrupt Mask Register

Name: CSI_INT_MSK_DPHY
Offset: 0x114
Reset: 0x00000000
Property: Read/Write

The following configuration values are valid for all listed bit names of this register:

0: The corresponding interrupt is not enabled.

1: The corresponding interrupt is enabled.

Bit	31	30	29	28	27	26	25	24
Access

42. CSI-2 Demultiplexer Controller (CSI2DC)

42.1 Description

The CSI-2 Demultiplexer Controller (CSI2DC) receives incoming data from a CSI-2 physical interface and filters packets based on their data type and virtual channel identifier.

The CSI2DC is fed with four clock domains — the CSI-2 data clock domain, the ISC clock domain, the configuration clock domain and the system bus clock domain. The CSI2DC performs clock domain crossing of incoming packets.

The CSI2DC integrates one video pipeline and one data pipeline. The video pipeline converts the byte stream to a pixel stream with an optional RAW decompression algorithm. This pipeline is connected to the Image Sensor Controller (ISC). The data pipeline propagates the data packets to a system bus client interface. The data buffers are then processed by the processor or by the centralized Direct Memory Access (DMA) controller using DMA requests.

The CSI2DC also includes a snoop controller that captures image data and packet attributes helping system bring up and debug.

The table below summarizes acronyms used in the following sections.

Table 42-1. Acronyms Used

CDC	Clock Domain Crossing
CSI	Camera Serial Interface
D-PHY	D Physical Layer
DMA	Direct Memory Access
DT	Data Type
FE	Frame End
FIFO	First In First Out
FS	Frame Start
GS	Generic Short
HS	High Speed; identifier for operation mode
ISC	Image Sensor Controller
ISP	Image Signal Processor
LE	Line End
LP	Low Power; identifier for operation mode
LS	Line Start
PFE	Parallel Front End
PHY	Physical Layer
RC	Row Count
RGB	Color representation (Red, Green, Blue)
SSP	Synchronization Short Packet
SW	Software
VC	Virtual Channel
WC	Word Count

YUV	Color representation (Y for luminance, U & V for chrominance)

42.2 Embedded Characteristics

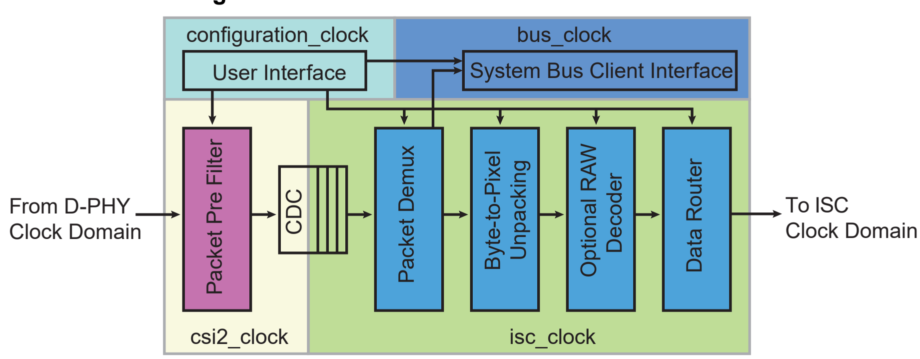
- CSI-2 Version 1.3 Specification-compliant Demultiplexer
- Four Virtual Channels
- Primary and Secondary Image Format
- RGB, YUV, RAW, Compressed RAW, User-defined Byte-based Packets
- Recommended Memory Storage Format or Single Pixel Per Clock Cycle
- Non-Image Data Packet and Generic Short Packet Support
- Image Data Snoop Controller (four entries)
- Programmable Video Pipeline Filter
- Programmable Data Pipeline Filter
- Progressive and Interlaced Content
- Programmable DMA Client Interface

42.3 Block Diagram

The CSI2DC includes four clocks:

- CSI-2 clock domain (CSI output): to sample the incoming byte stream along with protocol signals; up to 4 bytes per cycle are sampled.
- ISC clock domain (ISC MCLK output): to extract pixels from the data packet; one pixel per clock cycle is retrieved in RGB or RAW mode.
- Configuration clock domain: for configuration and status
- System bus clock domain: to read data from the RAM

Figure 42-1. CSI2DC Block Diagram



42.4 I/O Lines Description

Table 42-2. I/O Lines Description

Signal Name	Description	Type
ISC_PCK	Image Sensor Pixel clock	Input
ISC_D[11:0]	Image Sensor Data	Input
ISC_VSYNC	Image Sensor Vertical Synchro	Input
ISC_HSYNC	Image Sensor Horizontal Synchro	Input
ISC_FIELD	Field Identification Signal	Input

...........continued

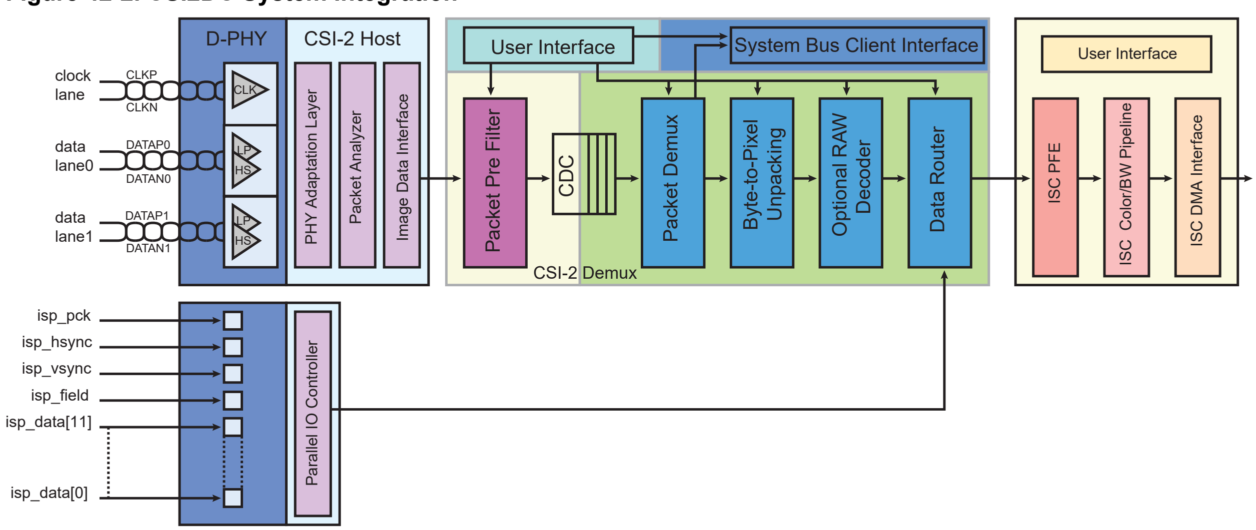
Signal Name	Description	Type
ISC_MCK	Image Sensor Main clock	Output
MIPI_CLKP	MIPI DPHY differential output clock lane	Input/Output
MIPI_CLKN		
MIPI_DP0	MIPI DPHY differential output data lane 0	Input/Output
MIPI_DN0		
MIPI_DP1	MIPI DPHY differential output data lane 1	Input/Output
MIPI_DN1		
MIPI_DP2	MIPI DPHY differential output data lane 2	Input/Output
MIPI_DN2		
MIPI_DP3	MIPI DPHY differential output data lane 3	Input/Output
MIPI_DN3		
MIPI_REXT	Calibration reference resistor	Input/Output

42.5 Functional Description

As shown in the following figure, the CSI2DC is connected to a CSI-2 protocol host side. The host side receives data from a CSI-2-compliant camera. The supported host protocol, Image Data Interface (IDI), uses a 32-bit data bus, vertical and horizontal timing accurate video synchronization signals, data type and virtual channel.

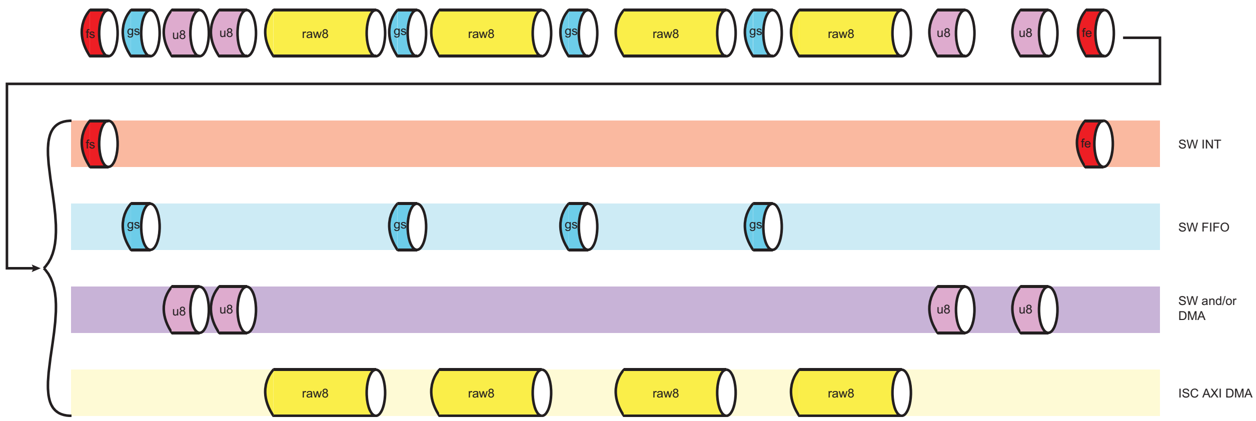
The CSI2DC receives a packet-based data stream, and outputs a pixel stream through its video pipeline connected to the Image Sensor Controller.

Figure 42-2. CSI2DC System Integration



A system bus client port is also available to retrieve non-image data that are locally saved into buffers. The dual buffer operation can be used with centralized DMA assistance or by using CPU accesses. When a packet is received, a snoop controller can be used to monitor CSI-2 traffic and identify that the desired information is successfully transmitted and received in the CSI2DC. Once configured, the video pipe filters packets and transmits a predefined image data type. Only relevant packets are forwarded to the ISC clock domain. A buffer is used to adjust clock domain crossing between the CSI-2 host domain and the ISC clock domain. A simple queue is used to pass data packets from the CSI-2 host clock domain to the system bus clock domain. The packet is routed based on its data type. The video pipe must be enabled to route data from the camera to the ISC. The data pipe must be enabled to route data from the camera to the system bus client interface.

Figure 42-3. Packet Demultiplexing Example



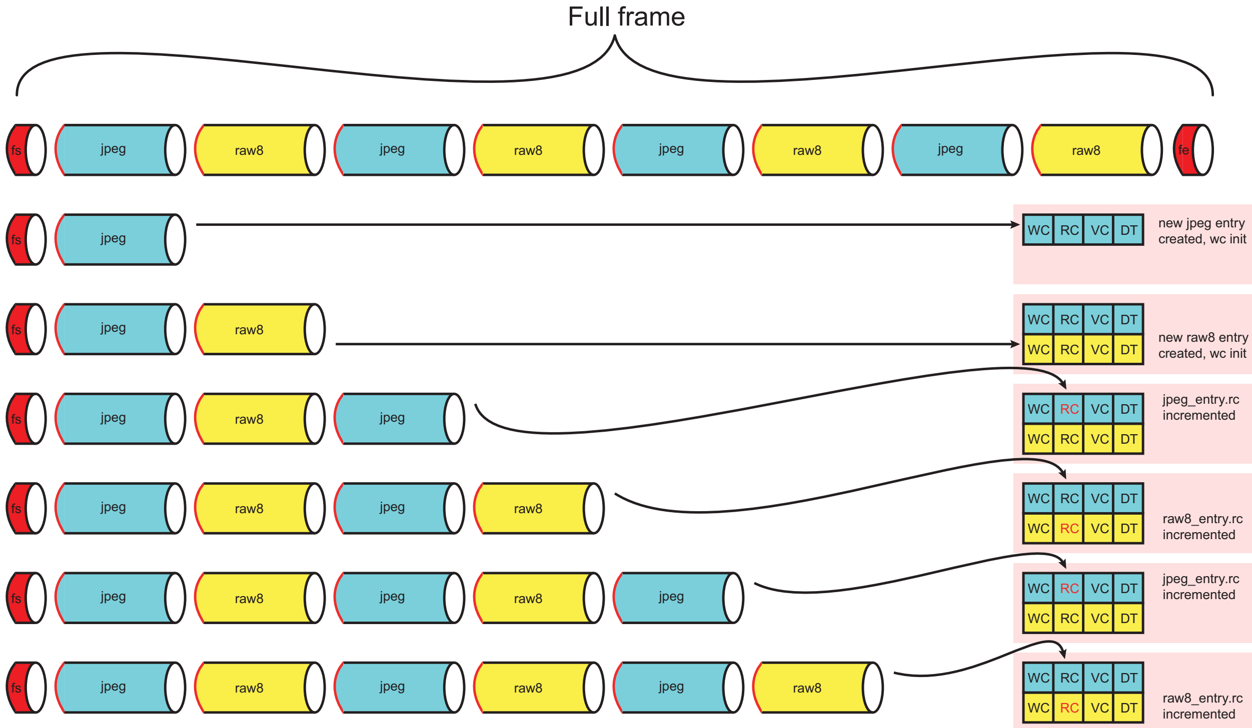
42.5.1 Image Data Snoop (IDS) Controller

The Image Data Snoop Controller allows packet monitoring for system-level bring up and debug. When a new image data packet is received, a new entry is created. An entry is composed of the data type, the virtual channel identifier, the word count and the row count. When a new packet with the same virtual channel identifier and data type is received, the row count field is incremented. The table of entry is transferred at the end to the user interface for processor analysis.

Table 42-3. CSI2DC Image Data Snoop Controller

Packet	Data Type	Image Data Snoop Support
Generic Short Packet (GSP)	GSP code 1 to 8	No
Generic Long Packet (GLP)	Null or blanking data	Interrupt
	Embedded 8-bit non-image data	Yes
	Reserved	GLP error interrupt reserved
YUV Image Data	YUV	Yes
	Reserved	YUV error interrupt
RGB Image Data	RGB	Yes
	Reserved	RGB error interrupt
RAW Image Data	RAW 6 to 14	Yes
	Reserved	RAW error interrupt
User-defined 8-bit Data	User-defined 8-bit data types 1 to 8	Yes

Figure 42-4. Image Data Snoop Controller



42.5.2 Synchronization Short Packet Demux

Short packets include Frame Synchronization packets and Line Synchronization packets. Each image must begin with a Frame Start (FS) Packet containing the Frame Start Code, and must end with a Frame End (FE) packet containing the Frame End code.

Table 42-4. Synchronization Short Packet Demultiplexing

Packet	Data Type	Handler
Synchronization Short Packet (SSP)	Frame Start Code	Per Virtual Channel Interrupt
	Frame End Code	Per Virtual Channel Interrupt
	Line Start Code (optional)	Per Virtual Channel Interrupt
	Line End Code (optional)	Per Virtual Channel Interrupt
	Reserved	SSP Error Interrupt reserved

The 16-bit frame number can be retrieved in the CSI2DC user interface. The Short Packet Data field indicates the frame number or the line number depending on the configuration. The behavior of the 16-bit frame number must be one of the following:

- Frame number is always 0, meaning that the frame number is inoperative.
- Frame number increments by 1 for every FS packet received with the same virtual channel identifier and is periodically reset to one, e.g. 1, 2, 1, 2, 1, 2 or 1, 2, 3, 4, 1, 2, 3, 4.
- The Frame number must be a non-value.

The behavior of the 16-bit line number must be one of the following:

- Line number is always zero — line number is inoperative.
- Line number increments by one for every Line Start (LS) packet received within the same virtual channel and the same data type. The line number is periodically reset to one for the first LS packet after a FS packet. The intended usage is for progressive scan.

- Line number increments by same arbitrary step value greater than one for every LS packet with the same virtual channel and the same data type. The line number is periodically reset to a non-zero arbitrary start value for the first LS after an FS packet. The arbitrary start value may be different between successive frames. The intended usage is for interlaced video data.

42.5.3 Generic Short Packet Demux

Generic Short Packets use the data type range [0x08, 0x0F]. These packets are retrieved through the CSI2DC user interface queue. An interrupt is raised as soon as the packet is received. The queue depth is set to 4 words. The data field retrieved is 22 bits wide and contains the 6-bit data type and a 16-bit data field. These values are passed to the application layer.

Table 42-5. Generic Short Packet Demultiplexing

Packet	Data Type	Handler
Generic Short Packet (GSP)	Code 1	Per Virtual Channel GSP queue
	Code 2	Per Virtual Channel GSP queue
	Code 3	Per Virtual Channel GSP queue
	Code 4	Per Virtual Channel GSP queue
	Code 5	Per Virtual Channel GSP queue
	Code 6	Per Virtual Channel GSP queue
	Code 7	Per Virtual Channel GSP queue
	Code 8	Per Virtual Channel GSP queue

42.5.4 Generic Long Packet Demux

The generic long packet contains three packet subclasses:

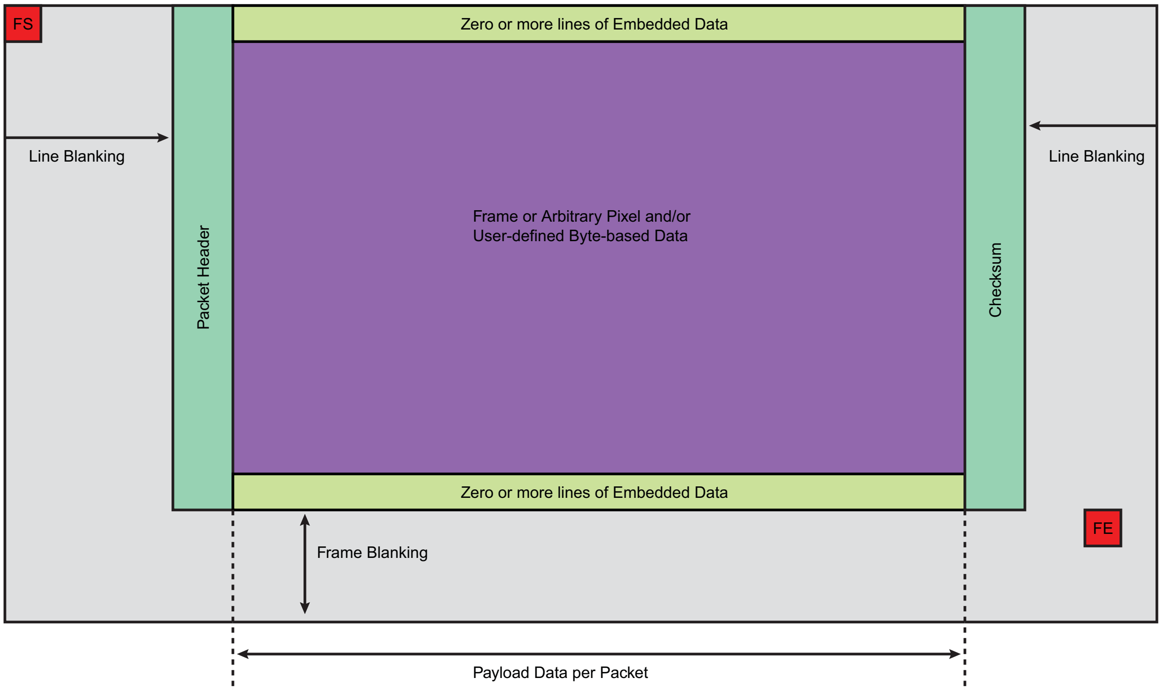
- NULL packet, data type set to 0x10
- Blanking data, data type set to 0x11
- Embedded 8-bit non-image data, data type set to 0x12

Null and blanking data packet content must be ignored by the application layer. Embedded 8-bit non-image data packets can be used to forward additional information from the camera to the host processor. These packets can be routed to the data pipe interface and read by the DMA interface or processor. The data payload must be a multiple of 8 bits.

Table 42-6. Generic Long Packet Demultiplexing

Packet	Data Type	Handler
Generic Long Packet (GLP)	Null	Null interrupt
	Blanking data	Data pipe
	Embedded 8-bit non-image data	Data pipe
	Reserved	GLP Error interrupt reserved

Figure 42-5. Generic Long Packet Embedded Information Packet



42.5.5 YUV Packet Demux

YUV data packets are always retrieved using the video pipe. CSI2DC reformats the stream to be compliant with the ISC video pipeline.

Table 42-7. YUV Image Data Demultiplexing

Packet	Data Type	Handler
YUV Image Data	YUV420 8-bit	Video pipe
	YUV420 10-bit	Video pipe
	Legacy YUV420 8-bit	Video pipe
	Reserved	YUV error interrupt
	YUV420 8-bit Chroma Shifted	Video pipe
	YUV420 10-bit Chroma Shifted	Video pipe
	YUV422 8-bit	Video pipe
	YUV422 10-bit	Video pipe

42.5.5.1 YUV 420 8-bit Legacy Mode

YUV 420 legacy data type is set to 0x1A.

42.5.8 User-Defined 8-bit Data

The User-Defined Data Type can be used to identify compressed data packets. CSI-2 specification indicates that a 12-7-12 compressed packet uses RAW7 data packing rule but the packet is tagged with User-Defined data type. The user-defined data type can be used to transmit arbitrary data such as JPEG or MPEG4.

Table 42-50. User-Defined 8-bit Data Demultiplexing

Packet	Data Type	Handler
User-defined 8-bit Data	User-defined 8-bit data type 1	Video pipe
	User-defined 8-bit data type 2	Video pipe
	User-defined 8-bit data type 3	Video pipe
	User-defined 8-bit data type 4	Video pipe
	User-defined 8-bit data type 5	Video pipe
	User-defined 8-bit data type 6	Video pipe
	User-defined 8-bit data type 7	Video pipe
	User-defined 8-bit data type 8	Video pipe

For user-defined data:

- The frame is transmitted as a sequence of arbitrarily-sized packets.
- The packet size may vary from packet to packet.
- Spacing between packets may vary.

42.5.9 CSI-2 Demux RAW Data Decompression Support

The CSI-2 implementation allows RAW data compression on the interface between the host processor and the camera module. Data compression schemes use an X-Y-Z naming convention where X is the number of bits per pixel in the original image, Y is the number of encoded (compressed) bits per pixel in the transmitted bit stream, and Z the number of decoded (uncompressed) bits per pixels.

Table 42-51. Decompression Mode Field Mapping to X-Y-Z Naming Convention

CSI2DC_VPCFG.DM	X-Y-Z CSI-2 Naming Rule
DECODER8TO12	12-8-12
DECODER7TO12	12-7-12
DECODER6TO12	12-6-12
DECODER8TO10	10-8-10
DECODER7TO10	10-7-10

...........continued	
CSI2DC_VPCFG.DM	**X-Y-Z CSI-2 Naming Rule**
DECODER6TO10	10-6-10

The data compression schemes specified in CSI-2 Annex E are lossy and are designed to encode each line independently.

Table 42-52. Decoder Output Formatting

CSI2DC_VPCFG.DM	RAW_DECODER[11:0]
DECODER8TO12	XDECO[11:0]
DECODER7TO12	XDECO[11:0]
DECODER6TO12	XDECO[11:0]
DECODER8TO10	XDECO[9:0]
DECODER7TO10	XDECO[9:0]
DECODER6TO10	XDECO[9:0]

Bit	7	6	5	4	3	2	1	0
	HLC[3:0]				SECDEDN	ULC	GPIOSEL	MIPIFRN
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 7:4 – HLC[3:0] CSI2DC Output Waveform Inter-line Minimum Delay
Inserts a minimal delay of (HLC+1) clock cycles between each line.

Bit 3 – SECDEDN Single Error Correction Double Error Detection Enable

Value	Description
0	Packet header error correction is activated.
1	Packet header error correction is disabled.

Bit 2 – ULC Use Optional Line Packet Delimiter

Value	Description
0	Line packets are not used to define the line boundary.
1	Line Start and Line End optional packets are used to activate and deactivate the line.

Bit 1 – GPIOSEL GPIO Parallel Interface Selection

Value	Description
0	The MIPI CSI-2 serial interface is activated.
1	The GPIO parallel interface is selected and internally routed to the Image Signal Processor.

Bit 0 – MIPIFRN MIPI Interface Free Running Clock

Value	Description
0	The sensor MIPI clock is free-running.
1	The sensor MIPI clock is gated.

42.6.2 CSI2DC Global Control Register

Name: CSI2DC_GCTLR
Offset: 0x04
Reset: –
Property: Write-only

Bit	31	30	29	28	27	26	25	24
Access

Access								
Reset								

Bit	7	6	5	4	3	2	1	0
							ARSTIP	RSTIP
Access							R	R
Reset							0	0

Bit 1 – ARSTIP Asynchronous Reset in Progress
This bit can be cleared only if the D-PHY clock is running.

Value	Description
0	No reset in progress for the asynchronous domain.
1	Asynchronous domain is being reset.

Bit 0 – RSTIP Reset in Progress

Value	Description
0	No reset in progress for the synchronous domain.
1	Synchronous domain is being reset.

42.6.4 CSI2DC Global Interrupt Enable Register

Name: CSI2DC_GIER
Offset: 0x0C
Reset: –
Property: Write-only

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Enables the corresponding interrupt.

Bit	31	30	29	28	27	26	25	24
Access

Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit 7 – DED Double Bit Error Detected Interrupt Status

Value	Description
0	No double bit error detected is pending.
1	A double bit error has been detected in the packet header. This bit is reset after the register read operation.

Bit 6 – SEC Single Bit Error Corrected Interrupt Status

Value	Description
0	No Single Bit Error Corrected interrupt is pending.
1	A single bit error has been detected and corrected in the packet header. This bit is reset after the register read operation.

Bit 5 – DP Data Pipe Interrupt Status

Value	Description
0	Either the interrupt source is masked at the DP level or no interrupt is pending for DP.
1	A Data Pipe interrupt is pending.

Bit 4 – VP Video Pipe Interrupt Status

Value	Description
0	Either the interrupt source is masked at the VP level or no interrupt is pending for VP.
1	A Video Pipe interrupt is pending.

Bit 3 – IDS Image Data Packet Snoop Controller Interrupt Status

Value	Description
0	Either the interrupt source is masked at the IDS level or no interrupt is pending for IDS.
1	A new Image Data Packet interrupt is pending.

Bit 2 – GLP Generic Long Packet Interrupt Status

Value	Description
0	Either the interrupt source is masked at the GLP level or no interrupt is pending for GLP.
1	A Generic Long Packet interrupt is pending.

Bit 1 – GSP Generic Short Packet Interrupt Status

Value	Description
0	Either the interrupt source is masked at the GSP level or no interrupt is pending for GSP.
1	A Generic Short Packet interrupt is pending.

Bit 0 – SSP Synchronization Short Packet Interrupt Status

Value	Description
0	Either the interrupt source is masked at the SSP level or no interrupt is pending for SSP.
1	A Synchronization Short Packet interrupt is pending.

42.6.8 CSI2DC SSP Interrupt Enable Register

Name: CSI2DC_SSPIER
Offset: 0x1C
Reset: –
Property: Write-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
					RE[3:0]			
Access					W	W	W	W

	FE[3:0]				FS[3:0]			
Access	W	W	W	W	W	W	W	W
Reset	–	–	–	–	–	–	–	–

Bits 19:16 – RE[3:0] Reserved Short Packet Interrupt Enable

Value	Description
0	No effect.
1	Setting a bit at position i in the RE field will set the interrupt mask bit for virtual channel i, and this virtual channel can generate an interrupt when a Reserved Short Packet is detected.

Bits 15:12 – LE[3:0] Line End Interrupt Enable

Value	Description
0	No effect.
1	Setting a bit at position i in the LE field will set the interrupt mask bit for virtual channel i, and this virtual channel can generate an interrupt when a Line End is detected. Line Synchronization packets are optional.

Bits 11:8 – LS[3:0] Line Start Interrupt Enable

Value	Description
0	No effect.
1	Setting a bit at position i in the LS field will set the interrupt mask bit for virtual channel i, and this virtual channel can generate an interrupt when a Line Start is detected. Line Synchronization packets are optional.

Bits 7:4 – FE[3:0] Frame End Interrupt Enable

Value	Description
0	No effect.
1	Setting a bit at position i in the FE field will set the interrupt mask bit for virtual channel i, and this virtual channel can generate an interrupt when a Frame End is detected.

Bits 3:0 – FS[3:0] Frame Start Interrupt Enable

Value	Description
0	No effect.

Value	Description
1	Setting a bit at position i in the FS field will set the interrupt mask bit for virtual channel i, and this virtual channel can generate an interrupt when a Frame Start is detected.

42.6.9 CSI2DC SSP Interrupt Disable Register

Name: CSI2DC_SSPIDR
Offset: 0x20
Reset: –
Property: Write-only

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Setting a bit at position i in this field clears the interrupt mask bit for virtual channel i.

Bit	31	30	29	28	27	26	25	24

Bits 19:16 – RE[3:0] Reserved Short Packet Interrupt Mask

Value	Description
0	A bit cleared at position i in the field RE indicates that the Reserved Packet interrupt is masked for virtual channel i.
1	A bit set at position i in field RE indicates that Reserved Packet interrupt is activated for virtual channel i.

Bits 15:12 – LE[3:0] Line End Interrupt Mask

Value	Description
0	A bit cleared at position i in the field LE indicates that the Line End interrupt is masked for virtual channel i.
1	A bit set at position i in field LE indicates that Line End interrupt is activated for virtual channel i.

Bits 11:8 – LS[3:0] Line Start Interrupt Mask

Value	Description
0	A bit cleared at position i in the field LS indicates that the Line Start interrupt is masked for virtual channel i.
1	A bit set at position i in field LS indicates that Line Start interrupt is activated for virtual channel i.

Bits 7:4 – FE[3:0] Frame End Interrupt Mask

Value	Description
0	A bit cleared at position i in the field FE indicates that the Frame End interrupt is masked for virtual channel i.
1	A bit set at position i in field FE indicates that Frame End interrupt is activated for virtual channel i.

Bits 3:0 – FS[3:0] Frame Start Interrupt Mask

Value	Description
0	A bit cleared at position i in the field FS indicates that the Frame Start interrupt is masked for virtual channel i.

Value	Description
1	A bit set at position i in field FS indicates that Frame Start interrupt is activated for virtual channel i.

Access	W	W	W	W	W	W	W	W
Reset	–	–	–	–	–	–	–	–

Bit	7	6	5	4	3	2	1	0
	BL[3:0]				NU[3:0]			
Access	W	W	W	W	W	W	W	W
Reset	–	–	–	–	–	–	–	–

Bits 15:12 – RE[3:0] Reserved Packet Interrupt Enable Bit

Value	Description
0	No effect.
1	Setting a bit at position i in the RE field sets the interrupt mask bit for virtual channel i, and this virtual channel can generate an interrupt when a reserved long packet is detected. A reserved long packet includes data types from 0x13 to 0x17.

Bits 11:8 – EB[3:0] Embedded 8-bit Non-Image Data Interrupt Enable Bit

Value	Description
0	No effect.
1	Setting a bit at position i in the EB field sets the interrupt mask bit for virtual channel i, and this virtual channel can generate an interrupt when a non-image data packet is detected.

Bits 7:4 – BL[3:0] Blanking Data Interrupt Enable Bit

Value	Description
0	No effect.
1	Setting a bit at position i in the BL field sets the interrupt mask bit for virtual channel i, and this virtual channel can generate an interrupt when a Blank packet is detected.

Bits 3:0 – NU[3:0] Null Interrupt Enable Bit

Value	Description
0	No effect.
1	Setting a bit at position i in the NU field sets the interrupt mask bit for virtual channel i, and this virtual channel can generate an interrupt when a null long packet is detected.

42.6.29 CSI2DC GLP Interrupt Disable Register

Name: CSI2DC_GLPIDR
Offset: 0x80
Reset: –
Property: Write-only

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Setting a bit at position i in this field clears the interrupt mask bit for Virtual Channel i.

Bit	31	30	29	28	27	26	25	24

Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bits 15:12 – RE[3:0] Reserved Packet Interrupt Mask Bit

Value	Description
0	A bit cleared at position i in the field RE indicates that the Reserved Packet interrupt is masked for virtual channel i.
1	A bit set at position i in field NU indicates that the Reserved Packet interrupt is activated for virtual channel i.

Bits 11:8 – EB[3:0] Embedded 8-bit Non-Image Data Packet Interrupt Mask Bit

Value	Description
0	A bit cleared at position i in the field EB indicates that the embedded data packet interrupt is masked for virtual channel i.
1	A bit set at position i in field EB indicates that the embedded data packet interrupt is activated for virtual channel i.

Bits 7:4 – BL[3:0] Blanking Data Packet Interrupt Mask Bit

Value	Description
0	A bit cleared at position i in the field BL indicates that the Blanking Data Packet interrupt is masked for virtual channel i.
1	A bit set at position i in field BL indicates that the Blanking Data Packet interrupt is activated for virtual channel i.

Bits 3:0 – NU[3:0] Null Packet Interrupt Mask Bit

Value	Description
0	A bit cleared at position i in the field NU indicates that the Null Packet interrupt is masked for virtual channel i.
1	A bit set at position i in field NU indicates that the Null Packet interrupt is activated for virtual channel i.

Bits 15:12 – RE[3:0] Reserved Generic Long Packet Ready Interrupt Status Bit

Value	Description
0	A bit cleared at position i in the field BL indicates that no reserved packet interrupt is pending for virtual channel i.
1	A bit set at position i in the field BL indicates that a reserved packet interrupt is pending for virtual channel i.

Bits 11:8 – EB[3:0] Embedded 8-bit data Generic Long Packet Ready Interrupt Status Bit

Value	Description
0	A bit cleared at position i in the field EB indicates that no embedded data packet interrupt is pending for virtual channel i.
1	A bit set at position i in the field EB indicates that an embedded data packet interrupt is pending for virtual channel i.

Bits 7:4 – BL[3:0] Blanking Data Generic Long Packet Ready Interrupt Status Bit

Value	Description
0	A bit cleared at position i in the field BL indicates that no blanking data packet interrupt is pending for virtual channel i.
1	A bit set at position i in the field BL indicates that a blanking packet interrupt is pending for virtual channel i.

Bits 3:0 – NU[3:0] Null Generic Long Packet Ready Interrupt Status Bit

Value	Description
0	A bit cleared at position i in the field NU indicates that no null packet interrupt is pending for virtual channel i.
1	A bit set at position i in the field NU indicates that a null packet interrupt is pending for virtual channel i.

42.6.32 CSI2DC IDS Control Register

Access				W	W	W	W	W
Reset				–	–	–	–	–

Bit 4 – OVF Image Data Snoop Overflow Interrupt Enable

Value	Description
0	No effect.
1	Enables the Image Data Snoop Overflow interrupt.

Bits 3:0 – IDS[3:0] Image Data Snoop Interrupt Enable

Value	Description
0	No effect.
1	Setting a bit at position i in the IDS field will set the interrupt mask bit for table entry i, and this entry can generate an interrupt when an image data packet is captured by the snoop controller.

42.6.34 CSI2DC IDS Interrupt Disable Register

Name: CSI2DC_IDSIDR
Offset: 0x94
Reset: –
Property: Write-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16

Access				W	W	W	W	W
Reset				–	–	–	–	–

Bit 4 – OVF Image Data Snoop Overflow Interrupt Disable

Value	Description
0	No effect.
1	Disables the Image Data Snoop Overflow interrupt.

Bits 3:0 – IDS[3:0] Image Data Snoop Interrupt Disable

Value	Description
0	No effect.
1	Setting a bit at position i in the IDS field will clear the interrupt mask bit for table entry i.

42.6.35 CSI2DC IDS Interrupt Mask Register

Name: CSI2DC_IDSIMR
Offset: 0x98
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16

				OVF	IDS[3:0]			
Access				R	R	R	R	R
Reset				0	0	0	0	0

Bit 4 – OVF Image Data Snoop Overflow Interrupt Mask

Value	Description
0	No effect.
1	Indicates that the Image Data Snoop Overflow interrupt is activated.

Bits 3:0 – IDS[3:0] Image Data Snoop Interrupt Mask Bit

Value	Description
0	A bit cleared at position i in the field IDS indicates that the Image Data Snoop interrupt is masked for table entry i.
1	A bit set at position i in field IDS indicates that Image Data Snoop interrupt is activated for table entry i.

42.6.36 CSI2DC IDS Interrupt Status Register

Name: CSI2DC_IDSISR
Offset: 0x9C
Reset: 0x00000000
Property: Read-only

Access				R	R	R	R	R
Reset				0	0	0	0	0

Bit 4 – OVF Image Data Snoop Overflow Interrupt Status

Value	Description
0	No effect.
1	Indicates that the IDS controller captured more than 4 entries.

Bits 3:0 – IDS[3:0] Image Data Snoop Interrupt Status Bit

Value	Description
0	A bit cleared at position i in the field IDS indicates that no Image Data Snoop interrupt is pending for virtual channel i.
1	A bit set at position i in the field IDS indicates that a new Image Data Snoop entry interrupt is pending for table entry i.

42.6.37 CSI2DC IDS Entry Word 0 Register

Name: CSI2DC_IDSEW0Rx
Offset: 0xA0 + x*0x08 [x=0..3]

Bits 31:16 – RC[15:0] Row Count for Image Data Packet Captured
Row count for the current packet. The number of rows in the image is RC+1.

Bits 15:0 – WC[15:0] Word Count for Image Data Packet Captured
Packet word count.

42.6.39 CSI2DC Pipe Update Register

Name: CSI2DC_PUR
Offset: 0xC0
Reset: –
Property: Write-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
							DP	VP
Access							W	W
Reset							–	–

Bit 1 – DP Data Pipe Attributes Update

Value	Description
0	No effect.
1	Transfers current configuration to Data Pipe Configuration registers on the next Frame Start Packet detection if the FS packet virtual channel ID matches the CSI2DC_DPCFG.VC field. This field must be set after data pipe configuration, otherwise the settings will not be updated.

Bit 0 – VP Video Pipe Attributes Update

Value	Description
0	No effect.
1	Transfers current configuration to Video Pipe Configuration registers on the next Frame Start Packet detection if the FS packet virtual channel ID matches the CSI2DC_VPCFG.VC field. This field must be set after video pipe configuration, otherwise the settings will not be updated.

42.6.40 CSI2DC Pipe Update Status Register

Name: CSI2DC_PUSR
Offset: 0xC4
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
	SIP							
Access	R							
Reset	0							

Bit	23	22	21	20	19	18	17	16

Bit	7	6	5	4	3	2	1	0
							DP	VP
Access							R	R
Reset							0	0

Bit 31 – SIP Synchronization In Progress

Value	Description
0	No synchronization pending.
1	Synchronization across clock domain boundary is in progress. If the MIPI interface clock is gated, the synchronization procedure will wait for the first valid MIPI packet to activate the receiver clock.

Bit 1 – DP Data Pipe Update

Value	Description
0	No data pipe in progress.
1	Data pipe configuration is in progress. This bit is cleared at the next frame start packet if the virtual channel identifier matches the CSI2DC_DPCFG.VC field.

Bit 0 – VP Video Pipe Update

Value	Description
0	No video pipe in progress.
1	Video pipe configuration is in progress. This bit is cleared at the next frame start packet if the virtual channel identifier matches the CSI2DC_VPCFG.VC field.

42.6.41 CSI2DC Data Pipe Interrupt Enable Register

Name: CSI2DC_DPIER
Offset: 0xC8
Reset: –
Property: Write-only

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Enables the corresponding interrupt.

Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit 7 – LTE Packet Longer Than Expected

Value	Description
0	No LTE packet detected.
1	A packet has been received but the actual length is longer that the packet word count value.

Bit 6 – STE Packet Shorter Than Expected

Value	Description
0	No STE packet detected.
1	A packet has been received but the actual length is shorter that the packet word count value.

Bit 5 – DATOVF Data Overflow

Value	Description
0	No overflow detected.
1	Data overflow in the clock domain crossing FIFO.

Bit 4 – RXOVF1 Bank 1 Overflow

Value	Description
0	No overflow detected.
1	An overflow occurred in bank 1.

Bit 3 – RXOVF0 Bank 0 Overflow

Value	Description
0	No overflow detected.
1	An overflow occurred in bank 0.

Bit 2 – RXRDY1 Bank 1 Packet Received

Value	Description
0	No packet received in bank 1 since the last clear operation of the register.
1	A new packet has been captured in the data pipe.

Bit 1 – RXRDY0 Bank 0 Packet Received

Value	Description
0	No packet received in bank 0 since the last clear operation of the register.
1	A new packet has been captured in the data pipe.

Bit 0 – CAPTURE Captured Frame

Value	Description
0	No frame captured on the data pipe interface since the last clear operation of the register.
1	A new frame has been captured in the data pipe.

42.6.45 CSI2DC Data Pipe Interrupt Clear Register

Reset	–	–	–	–	–	–	–	–

Bit 7 – LTE Packet Longer Than Expected Interrupt Clear Register

Value	Description
0	No effect.
1	Clears the LTE interrupt.

Bit 6 – STE Packet Shorter Than Expected Interrupt Clear Register

Value	Description
0	No effect.
1	Clears the STE interrupt.

Bit 5 – DATOVF Data Overflow Interrupt Clear Register

Value	Description
0	No effect.
1	Clears the Data Overflow interrupt.

Bit 4 – RXOVF1 Bank 1 Packet Overflow Interrupt Clear Register

Value	Description
0	No effect.
1	Clears the Bank 1 Packet Overflow interrupt.

Bit 3 – RXOVF0 Bank 0 Packet Overflow Interrupt Clear Register

Value	Description
0	No effect.
1	Clears the Bank 0 Packet Overflow interrupt.

Bit 2 – RXRDY1 Bank 1 Packet Received Interrupt Clear Register

Value	Description
0	No effect.
1	Clears the Bank 1 Packet Received interrupt.

Bit 1 – RXRDY0 Bank 0 Packet Received Interrupt Clear Register

Value	Description
0	No effect.
1	Clears the Bank 0 Packet Received interrupt.

Bit 0 – CAPTURE Captured Frame Interrupt Clear Register

Value	Description
0	No effect.
1	Clears the Captured Frame interrupt.

42.6.46 CSI2DC Data Pipe Enable Register

Name: CSI2DC_DPER
Offset: 0xDC

Bit 5 – PKTOVF Packet Overflow For Video Pipe Interrupt Mask

Value	Description
0	Packet Overflow For Video Pipe interrupt is masked.
1	Packet Overflow For Video Pipe interrupt is activated.

Bit 4 – LTE Packet Longer Than Expected Interrupt Mask

Value	Description
0	Packet Longer Than Expected interrupt is masked.
1	Packet Longer Than Expected interrupt is activated.

Bit 3 – STE Packet Shorter Than Expected Interrupt Mask

Value	Description
0	No packet shorter than expected since the last read of the register.
1	The Packet Shorter Than Expected interrupt is activated.

Bit 2 – CTLOVF Control Buffer Overflow Interrupt Mask

Value	Description
0	No Control Buffer Overflow since the last read of the register.
1	A Control Buffer Overflow has been detected.

Bit 1 – RATEOVF Rate Buffer Overflow Interrupt Mask

Value	Description
0	No Rate Buffer Overflow since the last read of the register
1	A Rate Buffer Overflow has been detected.

Bit 0 – CAPTURE Video Pipeline Capture Status

Value	Description
0	No frame capture since the last read of the register.
1	A frame has been captured in the video pipeline.

42.6.53 CSI2DC Video Pipe Enable Register

Reset	0	0	0	0	0	0	0	0

Bit 15 – RGB36MAP RGB Mapping

Value	Description
0	RGB data is packed and written to the output bus.
1	The RGB pixel is mapped onto the 36-bit bus, using pixel expansion and replication.

Bit 14 – PA ISC Post Adjustment

Value	Description
0	Post adjustment is disabled. Video pipe output data are LSB aligned (left untouched).
1	Post adjustment is enabled. Video pipe output data are MSB aligned according to 12-bit ISC data bus.

Bit 13 – RMS Recommended Memory Storage

Value	Description
0	CSI2DC outputs 1 pixel per component per clock cycle, compliant with the ISC processing engine.
1	CSI2DC generates a byte stream compliant with the CSI-2 specification memory format.

Bit 12 – DP2 Decoder Predictor 2 Selection

Value	Description
0	Predictor 1 is selected.
1	Predictor 2 is selected.

Bits 11:9 – DM[2:0] Decoder Mode
See CSI-2 Demux RAW Data Decompression Support.

Value	Name	Description
0	DECODER8TO12	Use the 8-bit to 12-bit decoding operation
1	DECODER7TO12	Use the 7-bit to 12-bit decoding operation
2	DECODER6TO12	Use the 6-bit to 12-bit decoding operation
3	DECODER8TO10	Use the 8-bit to 10-bit decoding operation
4	DECODER7TO10	Use the 7-bit to 10-bit decoding operation

Value	Name	Description
5	DECODER6TO10	Use the 6-bit to 10-bit decoding operation

Bit 8 – DE Decompression Enable

Value	Description
0	Decompression disabled.
1	Decompression enabled.

Bits 7:6 – VC[1:0] Virtual Channel Identifier
Must be configured with the camera virtual channel identifier.

Bits 5:0 – DT[5:0] Data Type
Must be configured with the desired image data type.

42.6.55 CSI2DC Video Pipe Column Register

Reset		0	0	0	0	0	0	0

Bit 6 – DTRE Data Type Remap Enable

Value	Description
0	Data type remap is disabled.
1	Data type remap is enabled.

Bits 5:0 – ADT[5:0] Alternate Data Type
When the remap is activated, the incoming data type is replaced with ADT.

43. Image Sensor Controller (ISC)

43.1 Description

The Image Sensor Controller (ISC) system manages incoming data from a parallel or MIPI sensor. It supports a single active interface. The parallel interface protocol can use a free-running clock or a gated clock strategy. It supports the ITU-R BT 656/1120 422 protocol with a data width of 8 bits or 10 bits and raw Bayer format. The internal image processor includes adjustable white balance, color filter array interpolation, color correction, gamma correction, defective pixel correction, green disparity correction, black level correction, edge adaptive level, horizontal and vertical downscaler, 12 bits to 10 bits compression, programmable color space conversion, horizontal and vertical chrominance subsampling module. The module also integrates a triple channel direct memory access controller host interface.

43.2 Embedded Characteristics

- MIPI CSI2 Interface Supported, Single Component per Clock Cycle or Recommended Memory Storage (RMS) Mode
- Parallel 14-bit Interface for Raw Bayer, YCbCr, Monochrome and JPEG Compressed Sensor Interface
- BT.601/656/1120 Video Interface Supported
- Progressive Systems and Segmented Frame Systems
- Raw Bayer, YCbCr, Luminance (Black and White) Pixel Format Supported
- Resolution up to 3264 x 2464
- Input Pixel Clock up to 266 MHz
- Camera Sensor Clock Generation for Parallel Interface
- Cropping
- Adjustable White Balance
- Raw Bayer Color Filter Array Interpolation
- Color Correction
- Gamma Correction
- Defective Pixel Correction
- Green Disparity Correction
- Black Level Correction
- Edge Adaptive Level
- Vertical And Horizontal Polyphase Downscaler, with 16 Phases and 4 Taps
- Color Space Conversion
- Contrast, Brightness, Hue and Saturation Control
- 4:4:4 to 4:2:2 Subsampler
- 4:2:2 to 4:2:0 Subsampler
- Rounding, Limiting and Packing unit
- Histogram Generation
- System Interface: Direct Memory Access Interface with Packed, Semi Planar and Planar output format
- Output Memory Format: 16 bpp RGB, 32 bpp RGB, 16 bpp, YCbCr 444, YCbCr 422, YCbCr 420, up to 14 bit raw Bayer

43.3 Block Diagram and Use Cases

43.3.1 Functional Diagrams

Figure 43-1. ISC Block Diagram with Active MIPI Interface

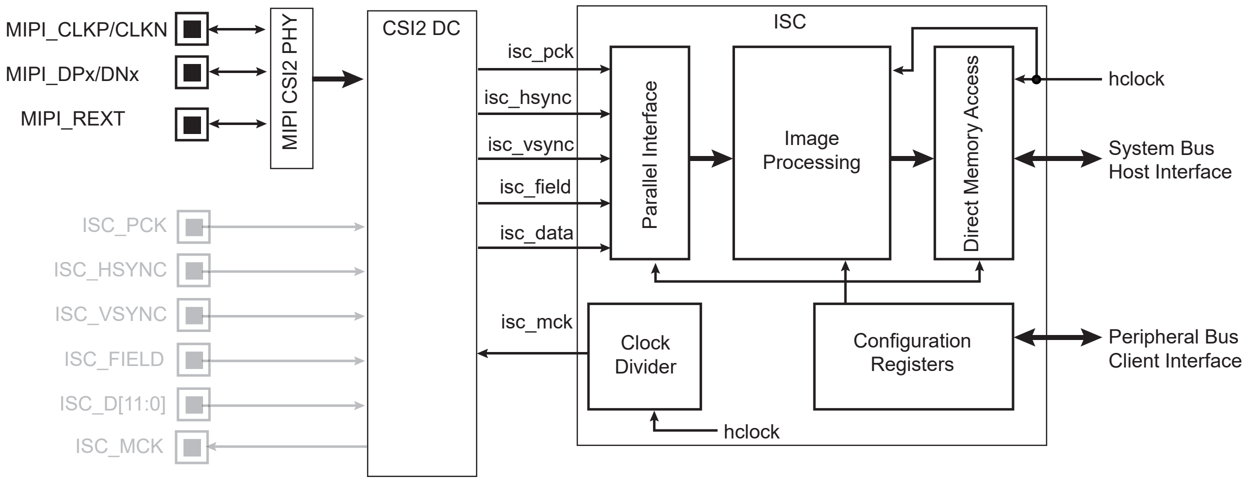

Figure 43-2. ISC Block Diagram with Active Parallel Interface

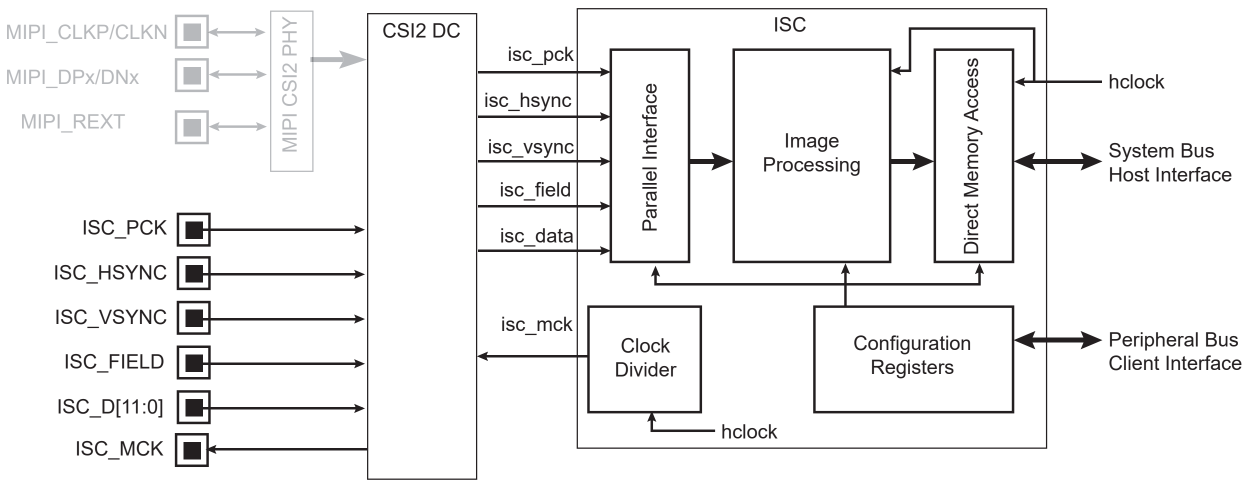

Figure 43-3. ISC Raw Bayer Signal Processor

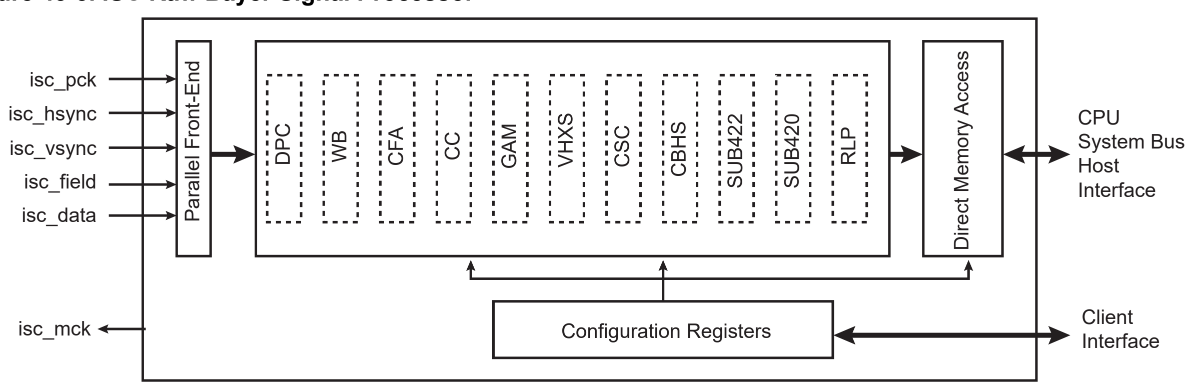

The ISC video pipeline integrates the following submodules:

- DPC: Defective pixel correction, also including a Green Disparity Correction (GDC), Black Level Correction (BLC), Edge Adaptive Level (EAL)

- PFE: Parallel Front End to sample the camera sensor input stream
- WB: Programmable white balance in the Bayer domain
- CFA: Color filter array interpolation module
- CC: Programmable color correction
- GAM: Gamma correction
- VHXS: Vertical and horizontal scaling engine
- CSC: Programmable color space conversion
- CBHS: Performs contrast, brightness, hue and saturation control
- SUB422: Performs YCbCr444 to YCbCr422 chrominance horizontal subsampling
- SUB420: Performs YCbCr422 to YCbCr420 chrominance vertical subsampling
- RLP: Performs rounding, range limiting and packing of the incoming data.

43.4 I/O Lines Description

Table 43-1. I/O Lines Description

Signal Name	Description	Type
ISC_PCK	Image Sensor Pixel clock	Input
ISC_D[11:0]	Image Sensor Data	Input
ISC_VSYNC	Image Sensor Vertical Synchro	Input
ISC_HSYNC	Image Sensor Horizontal Synchro	Input
ISC_FIELD	Field Identification Signal	Input
ISC_MCK	Image Sensor Main clock	Output
MIPI_CLKP	MIPI DPHY differential output clock lane	Input/Output
MIPI_CLKN		
MIPI_DP0	MIPI DPHY differential output data lane 0	Input/Output
MIPI_DN0		
MIPI_DP1	MIPI DPHY differential output data lane 1	Input/Output
MIPI_DN1		
MIPI_REXT	Calibration reference resistor	Input/Output

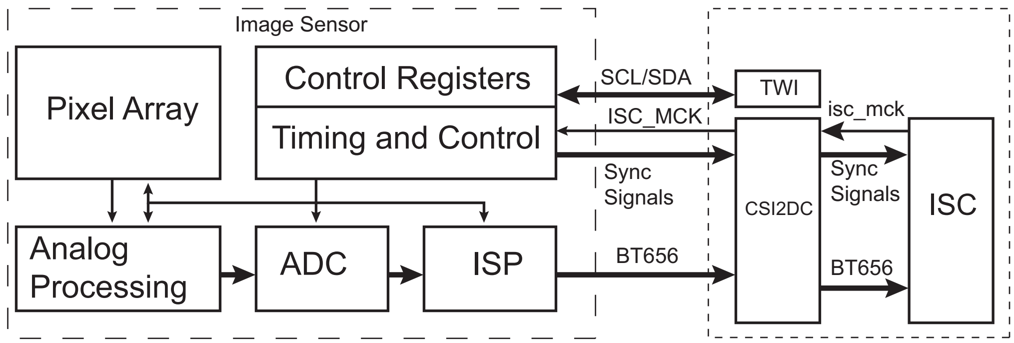

Figure 43-9. Sensor with JPEG Output

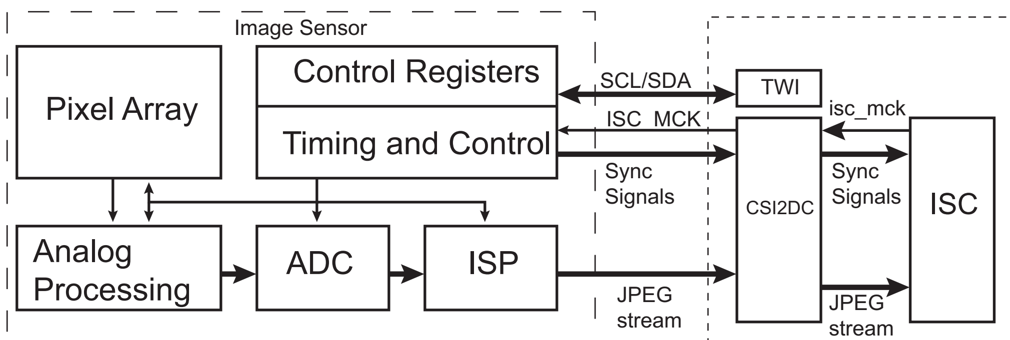

Figure 43-10. Serial CMOS Sensor with External Parallel Bridge

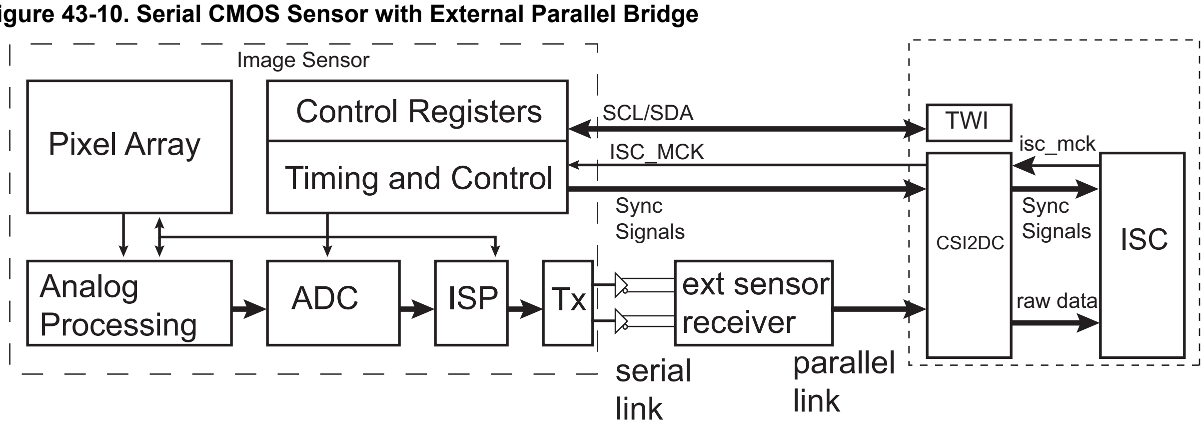


43.5 Product Dependencies

43.5.1 I/O Lines

The parallel interface pins used for interfacing the ISC are multiplexed with the PIO lines. The programmer must first program the PIO controller to assign the ISC pins to their peripheral function. If I/O lines of the ISC are not used by the application, they can be used for other purposes by the PIO controller.

When the MIPI link is used to interface the ISC, refer to the section "Camera Serial Interface (CSI)" to enable the MIPI inputs (not multiplexed with PIO lines).

43.5.2 Power Management

The ISC peripheral clock (hclock) is not continuously provided to the ISC. The programmer must first enable the ISC clock in the Power Management Controller (PMC) before using the ISC.

When the MIPI link is used to interface the ISC, refer to the sections "Camera Serial Interface (CSI)" to enable the MIPI PHY and "CSI-2 Demultiplexer Controller (CSI2DC)".

43.5.3 Interrupt Sources

The ISC interrupt line is connected on one of the internal sources of the Interrupt Controller. Using the ISC interrupt requires the Interrupt Controller to be programmed first.

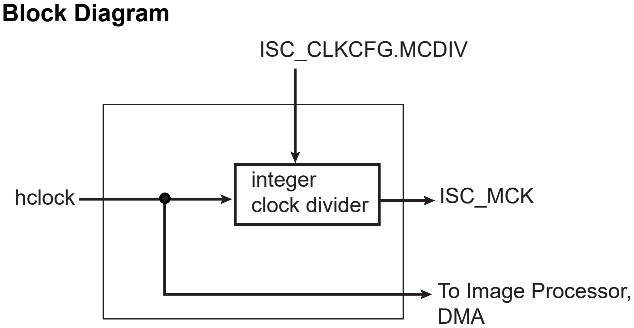
43.6 Functional Description

43.6.1 ISC Clock Management

The ISC module provides the ISC_MCK output clock to the CSI2 Demultiplexer Controller (CSI2DC), which transfers video stream from the MIPI CSI2 clock domain to the ISC_MCK clock domain. See Figure 43-1 and Figure 43-2.

The ISC_MCK clock has one programmable clock divider (ISC_CLKCFG.MCDIV). The clock is enabled using ISC_CLKEN.MCEN.

Figure 43-11. Clock Divider Block Diagram



The ISC is designed to accept input signals that are asynchronous to the hclock.

Synchronization is done internally as long as the following relationship holds:

- isc_pck frequency is lower than or equal to hclock frequency,

43.6.1.1 Software Requirement

A software write operation to the ISC_CLKEN or ISC_CLKDIS register requires double clock domain synchronization and is not permitted when the ISC_CLKSR.SIP is asserted.

43.6.2 Parallel Interface Timing Description

The parallel interface protocol supports two operating modes.

Figure 43-12. Free-Running Pixel Clock

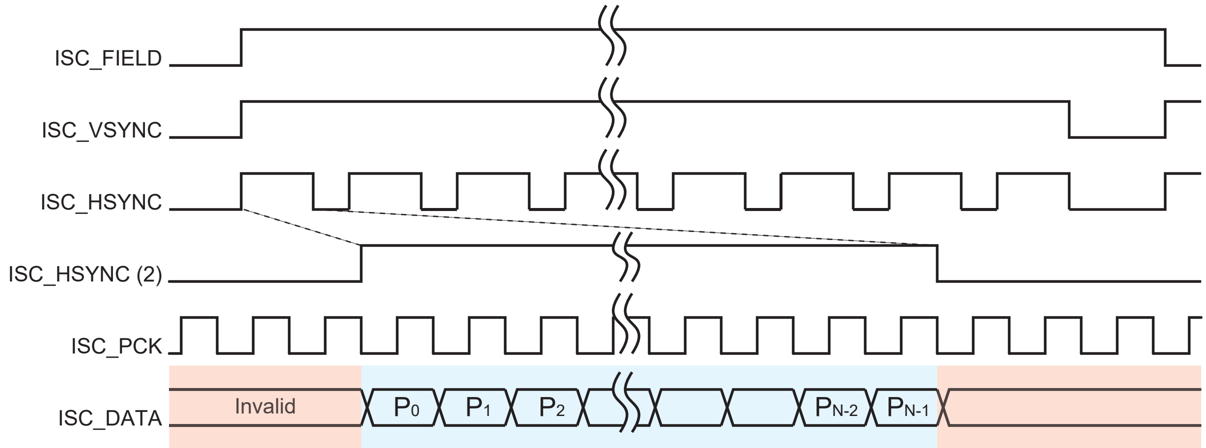


Figure 43-13. Gated Pixel Clock

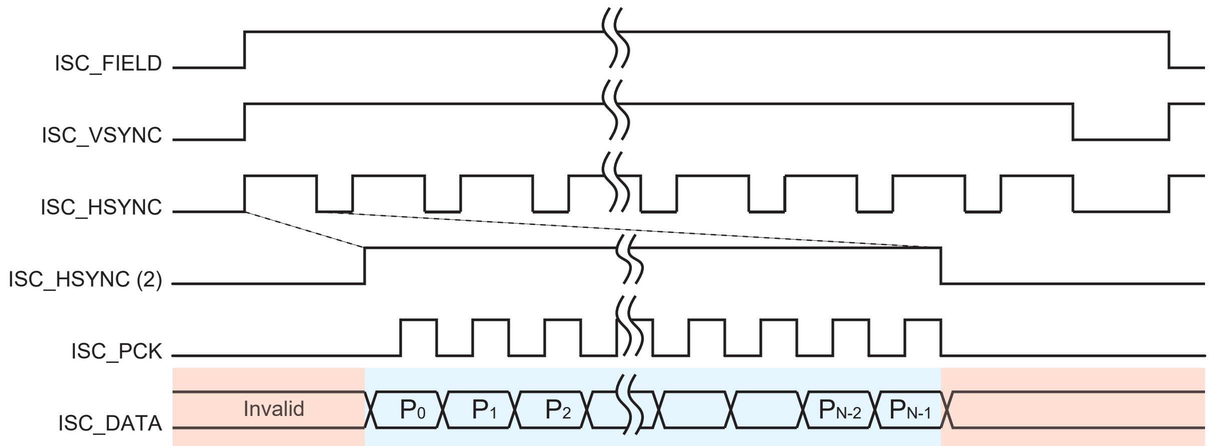

43.6.3 BT.601/656/1120 Embedded Timing Synchronization Operation

The ISC module supports embedded synchronization decoding. When the ISC_PFE_CFG0.CCIR656 is set, the decoder is activated and signals isc_vsync and isc_hsync are not used to decode the valid pixels. If the CCIR10_8N is set, the bitstream is 10 bits wide, otherwise it is only 8 bits wide. When the ISC_PFE_CFG0.CCIR_CRC is set, the decoder automatically corrects the error.

Figure 43-14. Field/Segment Timing Relationship for Interlaced and Segmented Frame Systems

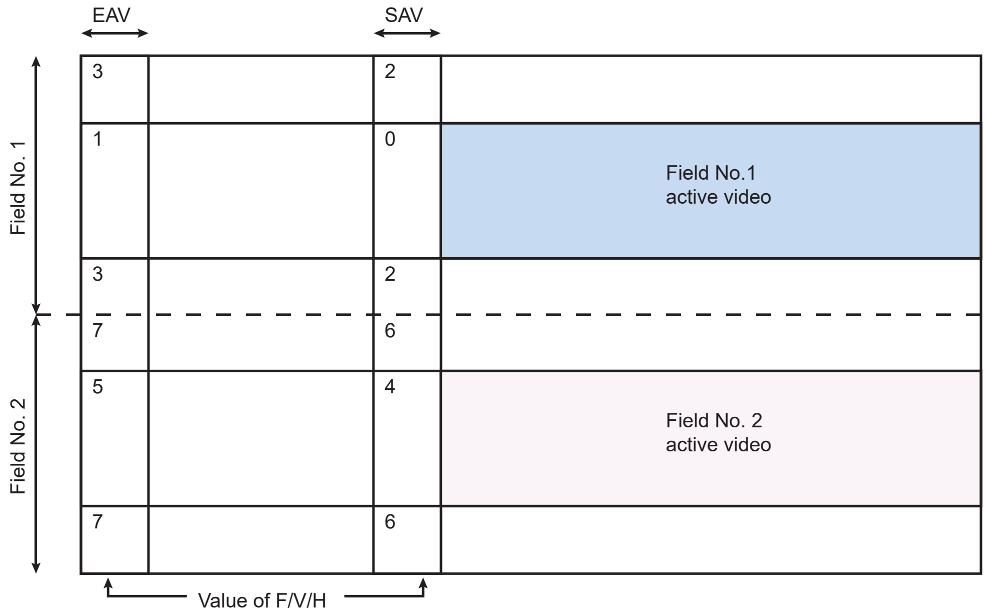

Figure 43-15. Frame Timing Relationship for Progressive Systems

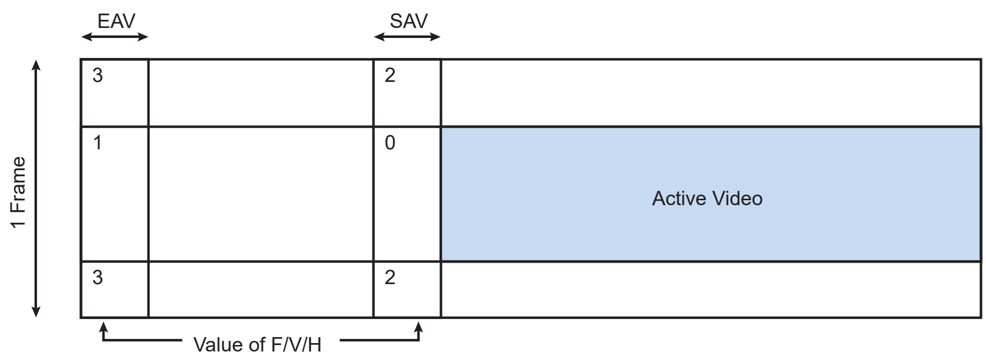

43.6.4 Parallel Interface External Sensor Connections

43.6.4.1 YCbCr, 10-bit CCIR656 with Embedded Synchronization

This mode is activated when ISC_PFE_CFG0.CCIR656 and ISC_PFE_CFG0.CCIR10_8N are both set.

Interface Bit	First Word	Second Word	Third Word	Fourth Word
ISC_DATA[11](MSB)	1	0	0	1
ISC_DATA[10]	1	0	0	F
ISC_DATA[9]	1	0	0	V

43.6.4.3 Raw Bayer Parallel Interface

The table below shows how to connect the data bus of a raw Bayer sensor.

Interface	Bayer 12-bit	Bayer 11-bit	Bayer 10-bit	Bayer 9-bit	Bayer 8-bit
ISC_DATA[11](MSB)	DOUT[11]	DOUT[10]	DOUT[9]	DOUT[8]	DOUT[7]
ISC_DATA[10]	DOUT[10]	DOUT[9]	DOUT[8]	DOUT[7]	DOUT[6]
ISC_DATA[9]	DOUT[9]	DOUT[8]	DOUT[7]	DOUT[6]	DOUT[5]
ISC_DATA[8]	DOUT[8]	DOUT[7]	DOUT[6]	DOUT[5]	DOUT[4]
ISC_DATA[7]	DOUT[7]	DOUT[6]	DOUT[5]	DOUT[4]	DOUT[3]
ISC_DATA[6]	DOUT[6]	DOUT[5]	DOUT[4]	DOUT[3]	DOUT[2]
ISC_DATA[5]	DOUT[5]	DOUT[4]	DOUT[3]	DOUT[2]	DOUT[1]
ISC_DATA[4]	DOUT[4]	DOUT[3]	DOUT[2]	DOUT[1]	DOUT[0]
ISC_DATA[3]	DOUT[3]	DOUT[2]	DOUT[1]	DOUT[0]	Not Used
ISC_DATA[2]	DOUT[2]	DOUT[1]	DOUT[0]	Not Used	Not Used
ISC_DATA[1]	DOUT[1]	DOUT[0]	Not Used	Not Used	Not Used
ISC_DATA[0]	DOUT[0]	Not Used	Not Used	Not Used	Not Used

43.6.4.4 Monochrome Parallel Interface

The table below shows how to connect the data bus of a Monochrome sensor.

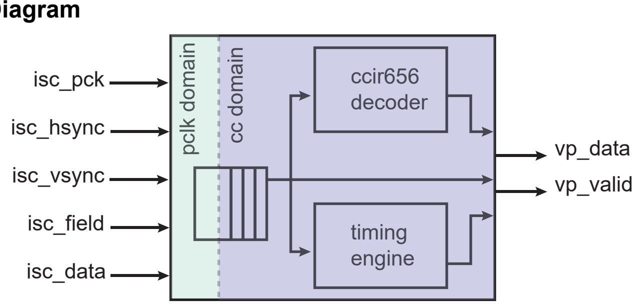
Interface	Mono 12-bit	Mono 11-bit	Mono 10-bit	Mono 9-bit	Mono 8-bit
ISC_DATA[11](MSB)	DOUT[11]	DOUT[10]	DOUT[9]	DOUT[8]	DOUT[7]
ISC_DATA[10]	DOUT[10]	DOUT[9]	DOUT[8]	DOUT[7]	DOUT[6]
ISC_DATA[9]	DOUT[9]	DOUT[8]	DOUT[7]	DOUT[6]	DOUT[5]
ISC_DATA[8]	DOUT[8]	DOUT[7]	DOUT[6]	DOUT[5]	DOUT[4]
ISC_DATA[7]	DOUT[7]	DOUT[6]	DOUT[5]	DOUT[4]	DOUT[3]
ISC_DATA[6]	DOUT[6]	DOUT[5]	DOUT[4]	DOUT[3]	DOUT[2]
ISC_DATA[5]	DOUT[5]	DOUT[4]	DOUT[3]	DOUT[2]	DOUT[1]
ISC_DATA[4]	DOUT[4]	DOUT[3]	DOUT[2]	DOUT[1]	DOUT[0]
ISC_DATA[3]	DOUT[3]	DOUT[2]	DOUT[1]	DOUT[0]	Not Used
ISC_DATA[2]	DOUT[2]	DOUT[1]	DOUT[0]	Not Used	Not Used
ISC_DATA[1]	DOUT[1]	DOUT[0]	Not Used	Not Used	Not Used
ISC_DATA[0]	DOUT[0]	Not Used	Not Used	Not Used	Not Used

43.6.5 MIPI Interface Mapping

When operating with a MIPI interface, CSI2DC maps the pixel content on the input data bus according to the data format. Refer to Functional Description in the section “CSI-2 Demultiplexer Controller (CSI2DC)”.

43.6.6 Parallel Front End (PFE) Module

Figure 43-16. PFE Block Diagram



The Parallel Front End module performs data resampling across clock domain boundary. It includes a CCIR656 decoder used to convert a standard ITU-R BT.656 stream to 24-bit digital video. It also generates pixels, syncs flags and valid signals to the main video pipeline. It ouputs field, video and synchronization signals. The PFE can optionally crop and limit the incoming pixel stream to a predefined horizontal and vertical value. By default, the PFE only relies on the input horizontal and vertical references to sample the incoming pixel stream. A pixel is sampled if, and only if, the vertical and horizontal synchronizations are valid and a pixel clock edge is detected. ISC_PFE_CFG0.BPS shows the number of bits per sample.

When operating with a parallel interface, the PFE module outputs a 12-bit data on the vp_data[11:0] bus, and asserts the vp_valid signal when the data can be sampled

PFE vp_data Mapping	Raw Bayer 12-bit	Raw Bayer 10-bit	YUV422 8-bit	YUV422 10-bit	Mono 12-bit
vp_data[39:12]	–	–	–	–	–
vp_data[11]	RGGB[11]	RGGB[9]	YC422[7]	YC422[9]	Y[11]

...........continued					
PFE vp_data Mapping	**Raw Bayer** 12-bit	**Raw Bayer** 10-bit	**YUV422** 8-bit	**YUV422** 10-bit	**Mono** 12-bit
vp_data[10]	RGGB[10]	RGGB[8]	YC422[6]	YC422[8]	Y[10]
vp_data[9]	RGGB[9]	RGGB[7]	YC422[5]	YC422[7]	Y[9]
vp_data[8]	RGGB[8]	RGGB[6]	YC422[4]	YC422[6]	Y[8]
vp_data[7]	RGGB[7]	RGGB[5]	YC422[3]	YC422[5]	Y[7]
vp_data[6]	RGGB[6]	RGGB[4]	YC422[2]	YC422[4]	Y[6]
vp_data[5]	RGGB[5]	RGGB[3]	YC422[1]	YC422[3]	Y[5]
vp_data[4]	RGGB[4]	RGGB[2]	YC422[0]	YC422[2]	Y[4]
vp_data[3]	RGGB[3]	RGGB[1]	YC422[7] or 0	YC422[1]	Y[3]
vp_data[2]	RGGB[2]	RGGB[0]	YC422[6] or 0	YC422[0]	Y[2]
vp_data[1]	RGGB[1]	RGGB[9] or 0	YC422[5] or 0	YC422[9] or 0	Y[1]
vp_data[0]	RGGB[0]	RGGB[8] or 0	YC422[4] or 0	YC422[8] or 0	Y[0]

Note: When ISC_PFE_CFG0.REP is set, missing vp_data LSBs are replaced with replicated LSBs of the incoming stream, otherwise they are forced to zero.

When operating with MIPI RGB or YUV formats, the PFE module copies up to 40-bit data from isc_data[39:0] bus on the vp_data[39:0] bus, and asserts the vp_valid signal when the data can be sampled.

The PFE module also includes logic to synchronize capture request with the incoming pixel stream. Two operating modes are available: Single Shot and Continuous Acquisition. When the ISC_PFE_CFG0.CONT is cleared, the ISC transfers a single image to memory,

Figure 43-17. Single Shot Mode

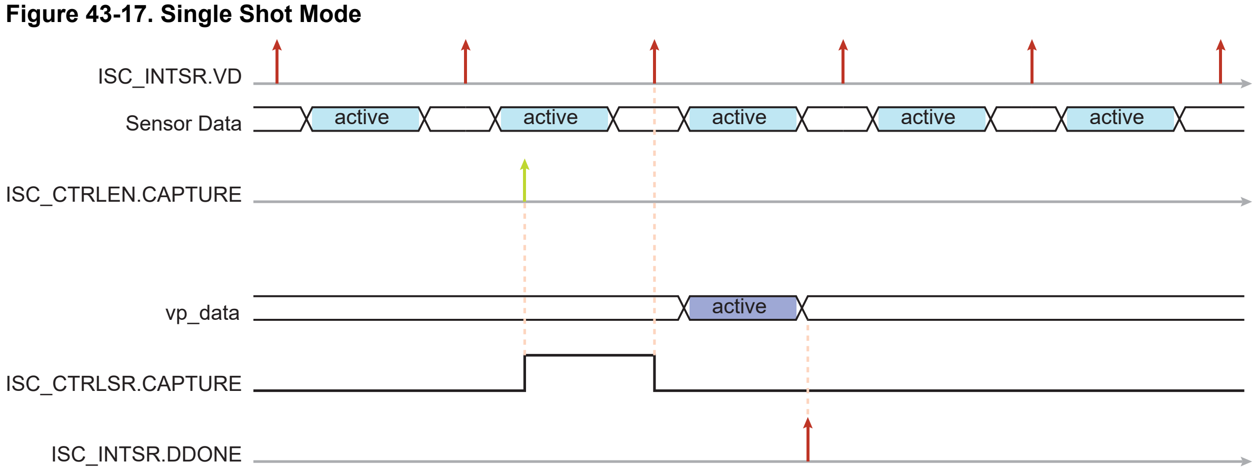


Figure 43-18. Continuous Acquisition Mode

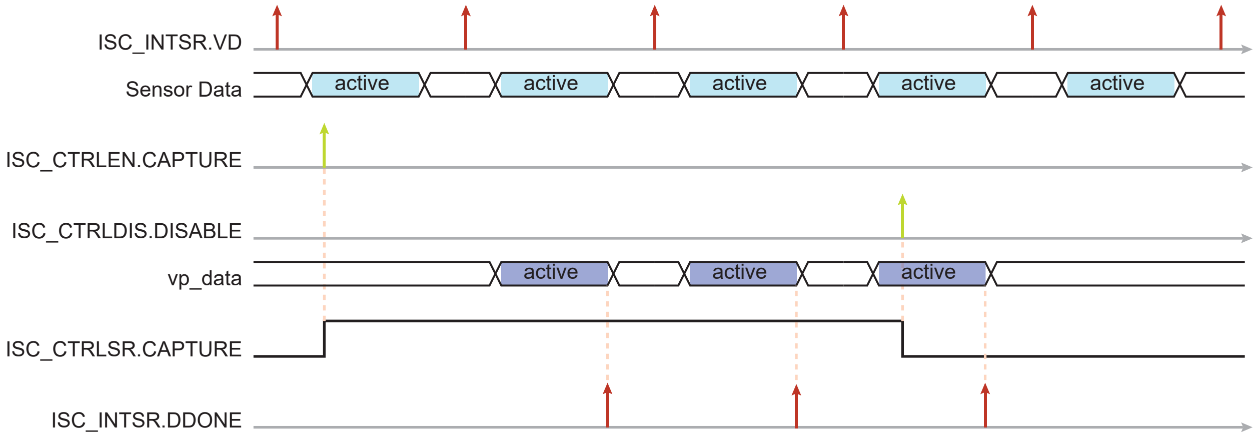
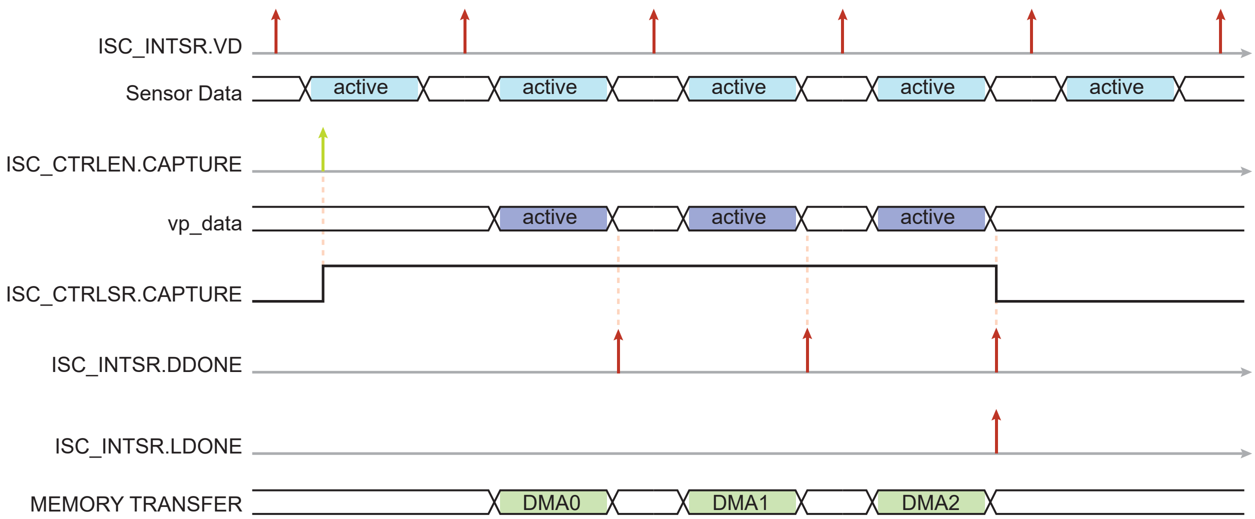


When Continuous Acquisition mode is activated (ISC_PFE_CFG0.CONT is set), the data transfer terminates when either a DMA end of list is reached, a software disable is performed or a software reset is activated. The ISC_INTSR.DDONE is set at the end of the DMA data transfer.

Figure 43-19. Continuous Acquisition, DMA Terminated



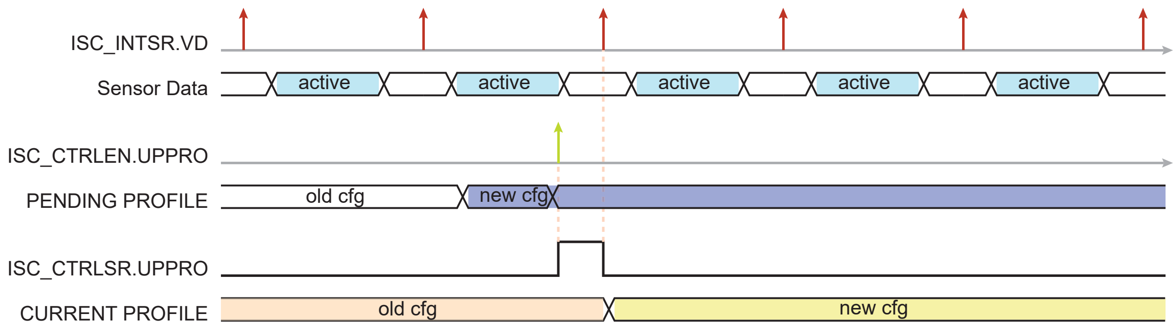
The linked list DMA transfer is terminated when an item of the list is programmed with ISC_DCTRL.DE cleared or when ISC_DNDA.NDA is equal to zero. This configuration also clears ISC_CTRLSR.CAPTURE and sets the ISC_INTSR.LDONE interrupt flag.

The linked list DMA transfer starts if ISC_DCTRL.DE is set and if ISC_DNDA.NDA is different from zero.

43.6.6.1 Update the ISC Profile

Each ISC register is double-buffered to simplify the software configuration and the synchronization with the associated frame buffer. When the configuration of the ISC is modified, ISC_CTRLEN.UPPRO must be set to transfer the configuration from the input buffer to the ISC video pipeline.

Figure 43-20. Update Profile Timing Diagram



43.6.6.2 Software Requirements

Writing to the ISC_CTRLEN or ISC_CTRLDIS register requires a double domain synchronization, so it is forbidden to write these registers when ISC_CTRLSR.SIP is asserted.

43.6.7 Defective Pixel Correction (DPC)

The ISC is able to detect and correct defective pixels.

The defective pixel correction is enabled by writing '1' to ISC_DPC_CTRL.DPCEN. The color filter array pattern of the image sensor driven by ISC must be configured in ISC_DPC_CFG.BAYCFG.

It is possible to adjust the processing performed by the defective pixel correction logic.

Several criteria can be activated to determine if a pixel is defective (edge interpolation, median threshold, closest pixel, average threshold).

The edge interpolation is enabled by writing ISC_DPC_CFG.EITPOL=1.

The median threshold is enabled by writing ISC_DPC_CFG.TM_ENABLE=1.

The closest pixel threshold is enabled by writing ISC_DPC_CFG.TC_ENABLE=1.

The average threshold is enabled by writing ISC_DPC_CFG.TA_ENABLE=1.

The different thresholds can be configured in ISC_DPC_THRESHM.THRESHM, ISC_DPC_THRESHC.THRESHC, ISC_DPC_THRESHA.THRESHA.

The triggering of a pixel correction can be triggered when all active criteria are met or only one is met by configuring the bit ISC_DPC_CFG.ND_MODE.

The number of corrected pixels by frame are reported in ISC_DPC_SR.COUNTER.

43.6.8 Green Disparity Correction (GDC)

The color filter array pattern alternates horizontal lines made of green and blue pixels with lines made of green and red pixels.

This pattern introduces green disparity from line to line that can automatically corrected by writing a '1' in ISC_DPC_CTRL.GDCEN.

The green disparity clipping value must be configured in ISC_DPC_CFG.GDCCLP.

43.6.9 Black Level Correction (BLC)

The black level provided by the image sensor is automatically corrected if ISC_DPC_CTRL.BLCEN=1.

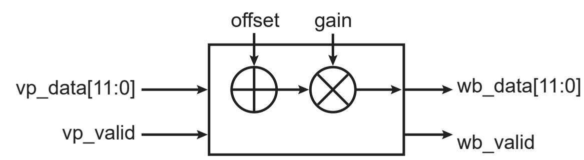
The black level offset provided by the image sensor (refer to the image sensor reference manual) must be configured in ISC_DPC_CFG.BLOFST.

43.6.10 White Balance (WB) Module

The White Balance (WB) module captures the vp_data bus from the PFE module when the vp_valid signal is asserted, and it generates a wb_data data along with its validity signal wb_valid.

When operating with Raw Bayer formats, and ISC_WB_CTRL.ENABLE is set, each Bayer color component (R, Gr, B, Gb) can be manually adjusted using an offset and a gain. The Bayer pattern is adjustable using ISC_WB_CFG.BAYCFG.

Figure 43-21. WB Block Diagram



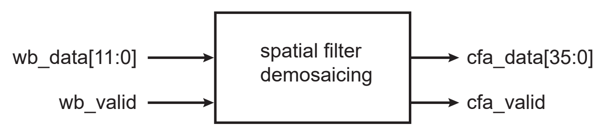
There are four {gain, offset} sets for each component. The output value is clipped.

ISC_WB_CTRL.ENABLE	WB_DATA Slice	Value
0	wb_data[11:0]	vp_data[11:0]
1	wb_data[11:0]	clipped((vp_data[11:0]+offset)*gain)

43.6.11 Color Filter Array (CFA) Interpolation Module

In a single-sensor system, each cell on the sensor has a specific color filter and microlens positioned above it. The raw data obtained from the sensor do not have the full R/G/B information at each cell position. Color interpolation is required to retrieve the missing components. The CFA module samples the wb_data[11:0] 12-bit bus when wb_valid is asserted and generates a 36-bit width data bus cfa_data[35:0] with the validity bit cfa_valid.

Figure 43-22. CFA Block Diagram



ISC_CFA_CTRL.ENABLE	CFA_DATA Slice	Value
0	cfa_data[35:24]	wb_data[11:0]
	cfa_data[23:12]	wb_data[11:0]
	cfa_data[11:0]	wb_data[11:0]
1	cfa_data[35:24]	R = spatial_filter_R(wb_data[11:0])
	cfa_data[23:12]	G = spatial_filter_G(wb_data[11:0])
	cfa_data[11:0]	B = spatial_filter_B(wb_data[11:0])

The filter kernel size is 5, and requires two additional lines to initialize the filter. When ISC_CFA_CFG.EITPOL is set, the missing information is interpolated from the nearest neighbor. If ISC_CFA_CFG.EITPOL is cleared, only valid pixels are used to initialize the filter kernel, but the output number of lines is less than the input number of lines. In that case, four lines are consumed to fill the kernel.

43.6.11.1 Frame Size Requirement when Edge Interpolation is Off, ISC_CFA_CFG.EITPOL Cleared

- Minimum number of rows (in): 5
- Minimum number of columns (in): 5
- Number or rows after CFA: Number of rows (in) - 4
- Number of columns after CFA: Number of columns (in) - 4

43.6.11.2 Frame Size Requirement when Edge Interpolation is On, ISC_CFA_CFG.EITPOL Set

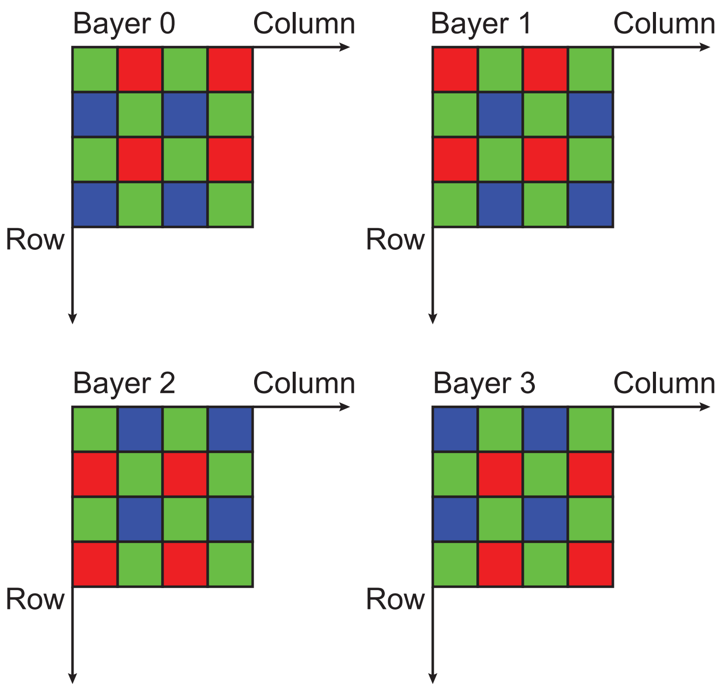
- Minimum number of rows (in): 3
- Minimum number of columns (in): 3
- Number of rows after CFA: Number of rows (in)
- Number of columns after CFA: Number of columns (in)

43.6.11.3 Bayer Mode and Edge Interpolation Description

When Edge Interpolation mode (ISC_CFA_CFG.EITPOL) is activated, dummy lines are generated using rows and columns replication.

The CFA module supports four sensor alignments using ISC_CFA_CFG.BAYCFG. See the figure below.

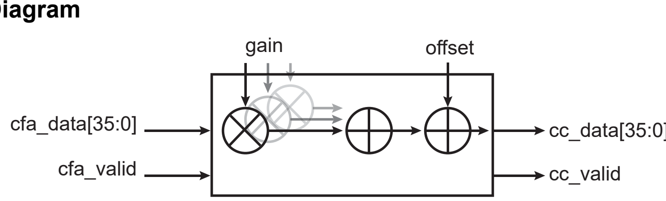
Figure 43-23. Supported Color Filter Array Patterns



43.6.12 Color Correction (CC) Module

RGB color correction is used to compensate for cross color bleeding in the filter used with the image sensor. The module samples the cfa_data[35:0] 36-bit bus when cfa_valid is asserted and generate a cc_data[35:0] 36-bit wide bus and a cc_valid signal.

Figure 43-24. CC Block Diagram



There are three {gain, offset} sets for color component R, G, B.

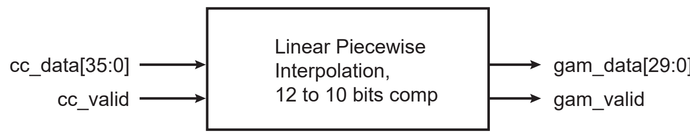
ISC_CC_CTRL.ENABLE	CC_DATA Slice	Value
0	cc_data[35:24]	cfa_data[11:0]
	cc_data[23:12]	cfa_data[11:0]
	cc_data[11:0]	cfa_data[11:0]
1	cc_data[35:24]	R=clipped(sum(cfa_data_x * gain_Rx) + offset_R)
	cc_data[23:12]	G=clipped(sum(cfa_data_x * gain_gx) + offset_g)
	cc_data[11:0]	B=clipped(sum(cfa_data_x * gain_Bx) + offset_B)

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \begin{bmatrix} \text{RRGAIN} & \text{RGGAIN} & \text{RBGAIN} \\ \text{GRGAIN} & \text{GGGAIN} & \text{GBGAIN} \\ \text{BRGAIN} & \text{BGGAIN} & \text{BBGAIN} \end{bmatrix} \times \begin{bmatrix} \text{cfa\_data}[35:24] \\ \text{cfa\_data}[23:12] \\ \text{cfa\_data}[11:0] \end{bmatrix} + \begin{bmatrix} \text{ROFST} \\ \text{GOFST} \\ \text{BOFST} \end{bmatrix}$$

43.6.13 Gamma Curve (GAM) Module

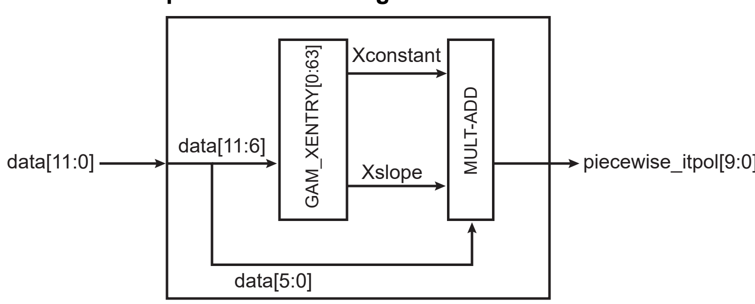
The GAM module samples the cc_data[35:0] bus when cc_valid is asserted, and generates gam_data[29:0] 30-bit width data along with the validity signal gam_valid. Imaging devices have non-linear characteristics, but the transfer function is approximated by a power function. The intensity of each of the linear RGB components is transformed to a non-linear signal through the use of the gamma correction submodule. The power function is linearly interpolated using 64 breakpoints. This also performs a 12-bit to 10-bit compression. The polynomial for the linear interpolation between breakpoints is i and i +1. Consequently, for each breakpoint, two values are required: constant and slope. The table values are programmable through the user interface when the gamma correction module is disabled (ISC_GAM_CTRL.ENABLE is cleared). ISC_GAM_RENTRY is used for Red gamma correction. ISC_GAM_GENTRY is used for Green gamma correction. ISC_GAM_BENTRY is used for Blue gamma correction. Each table entry is composed of a 10-bit (signed) slope and a 10-bit constant.

Figure 43-25. GAM Block Diagram



ISC_GAM_CTRL.ENABLE	ISC_GAM_CTRL.XLUT	GAM_DATA Slice	Value
0	0	gam_data[29:0]	cc_data[29:0]
1	0	gam_data[29:20]	cc_data[35:26]
		gam_data[19:10]	cc_data[23:14]
		gam_data[9:0]	cc_data[11:2]
1	1	gam_data[29:20]	R=piecewise_itpol(cc_data_r[35:24])
		gam_data[19:10]	G=piecewise_itpol(cc_data_r[23:12])
		gam_data[9:0]	B=piecewise_itpol(cc_data_r[11:0])

Figure 43-26. Piecewise Linear Interpolation Block Diagram

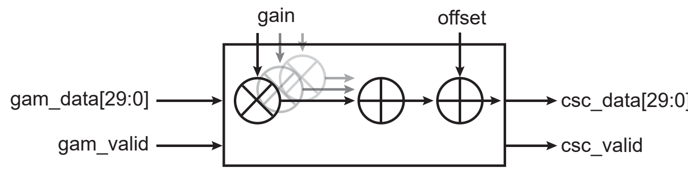


The interpolation consists of three tables that store the function values GAM_XENTRY[0:63] where X stands for R, G and B. The input of the table has six bits. It outputs a slope and a constant. The slope is later multiplied by the data lsb (6-bit) and added to a constant. The final value is the gamma-corrected value of the input. This module performs a 12-to-10 compression.

43.6.14 Color Space Conversion (CSC) Module

By converting an image from RGB to YCbCr color space, it is possible to separate Y, Cb and Cr information. The CSC samples the gam_data[29:0] 30-bit data bus, extracts YCbCr information from the sampled data, and then generates the color-converted data csc_data[29:0] and the validity signal csc_valid.

Figure 43-27. CSC Block Diagram



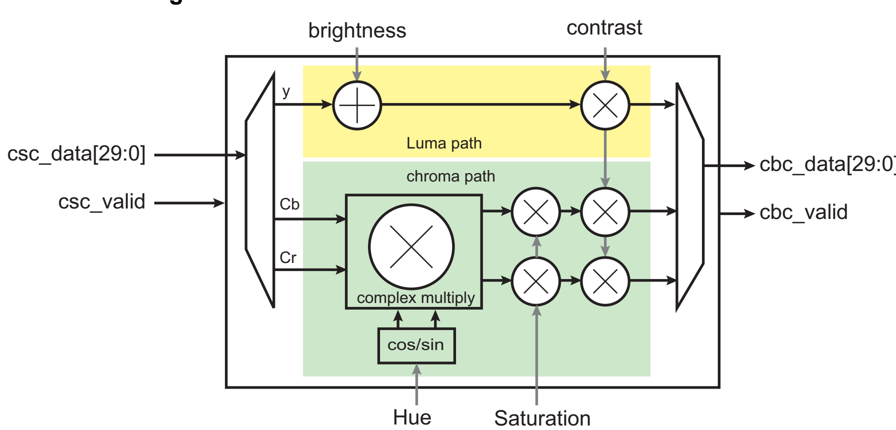
ISC_CSC_CTRL.ENABLE	CSC_DATA Slice	Value
0	csc_data[29:0]	gam_data[29:0]
1	csc_data[29:20]	Y = clipped(sum(gam_data_x * gain_Yx) + offset_y << 2)
	csc_data[19:10]	Cb = clipped(sum(gam_data_x * gain_Cbx)+offset_cb << 2)
	csc_data[9:0]	Cr = clipped(sum(gam_data_x * gain_Crx)+offset_cr << 2)

$$\begin{bmatrix} Y \\ \mathrm{CB} \\ \mathrm{CR} \end{bmatrix} = \begin{bmatrix} \mathrm{YR} & \mathrm{YG} & \mathrm{YB} \\ \mathrm{CBR} & \mathrm{CBG} & \mathrm{CBB} \\ \mathrm{CRR} & \mathrm{CRG} & \mathrm{CRB} \end{bmatrix} \times \begin{bmatrix} \mathrm{gam\_data}[29:20] \\ \mathrm{gam\_data}[19:10] \\ \mathrm{gam\_data}[9:0] \end{bmatrix} + \begin{bmatrix} \mathrm{YOFST} \\ \mathrm{CBOFST} \\ \mathrm{CROFST} \end{bmatrix}$$

43.6.15 Contrast, Brightness, Hue and Saturation

This module is for YUV formats purpose. Brightness Offset allows the Luminance to be adjusted. Hue is used for Chroma phase adjustment, and Color Saturation for Chroma amplitude. Contrast gain is applied on all pixel components (Luma and Chroma). The CBHS samples the csc_data[29:0] 30-bit bus when csc_valid is asserted and generates cbhs_data[29:0] with the validity signal cbc_valid.

Figure 43-28. CBHS Block Diagram



ISC_CBC_CTRL.ENABLE	ISC_CBC_CFG.CCIR	CBC_DATA Slice	Value
0	0	cbc_data[29:0]	csc_data[29:0]

...........continued			
ISC_CBC_CTRL.ENABLE	ISC_CBC_CFG.CCIR	CBC_DATA Slice	Value
1	0	cbc_data[29:20]	Y = clipped(contrast * (csc_data[29:20]+brightness))
		cbc_data[19:10]	Cb = clipped(saturation * contrast * (csc_data[19:10]*cos(hue) +csc_data[9:0]*sin(hue))
		cbc_data[9:0]	Cr = clipped(saturation * contrast * (csc_data[19:10]*sin(hue)-csc_data[9:0]*cos(hue))

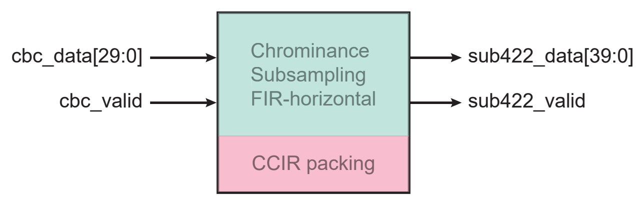
		cbc_data[9:0]	ccir656 stream with luminance correction

43.6.16 4:4:4 To 4:2:2 Chrominance Horizontal Subsampler (SUB422) Module

The color space conversion output stream is a full-bandwidth YCbCr 4:4:4 signal. The chrominance subsampling divides the horizontal chrominance sampling rate by two. A horizontal low pass filter is applied to avoid aliasing effect. The SUB422 module samples 444 full scale YCbCr cbc_data[29:0] 30-bit data, performs horizontal subsampling and generates the sub422_data[39:0] 40-bit data bus with its validity signal sub422_valid.

Figure 43-29. SUB422 Block Diagram



ISC_SUB422_CTRL.ENABLE	ISC_SUB422_CFG.CCIR	SUB422_DATA Slice	Value
0	0	sub422_data[29:0]	cbc_data[29:0]
1	0	sub422_data[39:30]	Y1= cbc_data1[29:20]
		sub422_data[29:20]	Y0 = cbc_data0[29:20]
		sub422_data[19:10]	Cb = filter_hor(cbc_data[19:10])
		sub422_data[9:0]	Cr = filter_hor(cbc_data[9:0])
1	1	sub422_data[39:30]	Y1 = cbc_data[9:0]
		sub422_data[29:20]	Y0 = cbc_data[9:0]
		sub422_data[19:10]	Cb = cbc_data[9:0]
		sub422_data[9:0]	Cr = cbc_data[9:0]

The filter_hor function included in the sub422 module is the chrominance horizontal filter.

sub422 Data Slice	YCbCr Mapping
sub422_data[39:30]	Y1 (sample n)
sub422_data[29:20]	Y0 (sample n-1)
sub422_data[19:10]	Cb (from filter)
sub422_data[9:0]	Cr (from filter)

The filter chrominance position is selectable through the use of ISC_SUB422_CFG.FILTER.

Figure 43-30. Cosited Filter Configuration

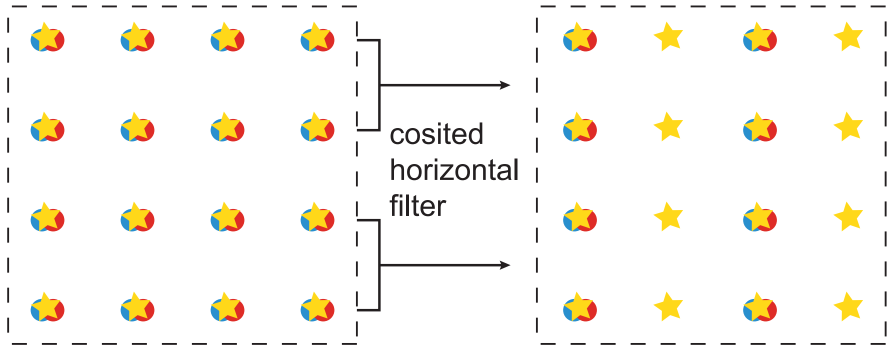


Figure 43-31. Centered Filter Configuration

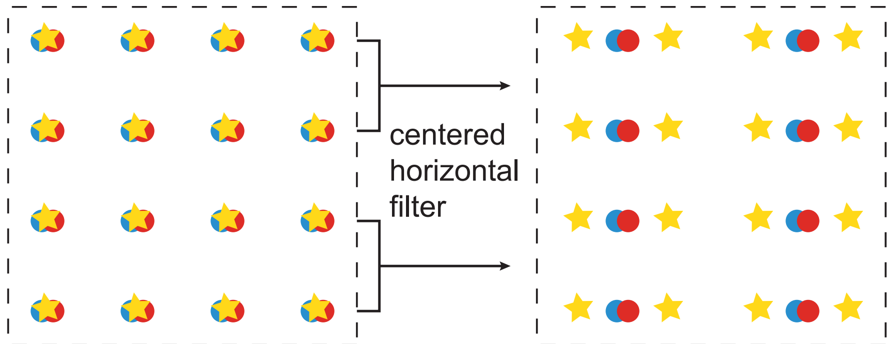


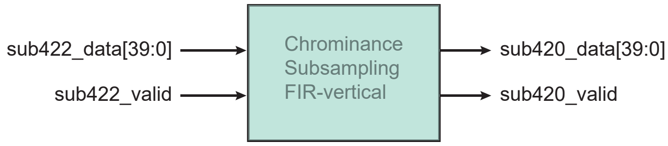
The SUB422 module performs luminance and chrominance packing. When the line length is odd, the missing luminance is a copy of the last but one luminance. It also means that the final dma stream written to memory is equal to the original horizontal size plus one when the line length is odd.

SUB422_DATA Slice	Even Line Length	Odd Line Length
sub422_data[39:30]	Y(n)	Y(n-1)
sub422_data[29:20]	Y(n-1)	Y(n-1)
sub422_data[19:10]	Cb (filtered)	Cb (filtered)
sub422_data[9:0]	Cr (filtered)	Cr (filtered)

43.6.17 4:2:2 To 4:2:0 Chrominance Vertical Subsampler (SUB420) Module

The chrominance subsampling divides the vertical chrominance sampling rate by two. A vertical low pass filter is applied to avoid aliasing effect. Two different filters are used when the source frame is interlaced, and the filter configuration depends on the field value (the field is propagated in the video pipeline).

Figure 43-32. SUB420 Block Diagram



The SUB420 module samples the sub422_data[39:0] 40-bit data when sub422_valid is asserted, then it performs a vertical subsampling and generates a valid sub420_data[39:0] 40-bit word and the corresponding sub420_valid signal.

ISC_CFA_CTRL.ENABLE	SUB420_DATA Slice	Value
0	sub420_data[39:0]	sub422_data[39:0]

...........continued

ISC_CFA_CTRL.ENABLE	SUB420_DATA Slice	Value
1	sub420_data[39:30]	Y1 = sub422_data[39:30]
	sub420_data[29:20]	Y0 = sub422_data[29:20]
	sub420_data[19:10]	Cb = filter_ver(sub422[19:10])
	sub420_data[9:0]	Cr = filter_ver(sub422[9:0])

The vertical filter is a two-tap filter; for progressive content the coefficient i {1, 1}. When an interlaced field is downsampled, the coefficients are different between the top and the bottom fields.

Figure 43-33. Vertical Chrominance Filter for Progressive Content (Cosited Chrominance Example)

SUB420 Input Number of Rows	SUB420 Luminance Rows	SUB420 Chrominance Rows
M rows, M odd	M rows	(M+1)/2 rows
M rows, M even	M rows	M/2 rows

43.6.18 Rounding, Limiting and Packing (RLP) Module

This module is used to round, limit and pack in the incoming pixel stream before the host DMA module. The RLP samples the sub420_data[39:0] 40-bit data bus and generates rlp_data[31:0] 32-bit data words with the associated validity signal rlp_valid.

43.6.19 DMA Interface

The descriptor-based DMA interface supports multiple buffers. A DMA stride value shows the offset between two consecutive lines (in bytes). If the stride is set to zero, the frame buffer is contiguous. When ISC_DCTRL.WB is set (Write Back), the DMA interface performs a single write operation to the ISC_DCTRL register, and sets ISC_DCTRL[7] to one and ISC_DCTRL[6] to the value of the frame field when interlaced content is being used. That means that interlaced fields are tagged with their relevant field values. The Write Back operation is always performed when the whole frame has been transferred to memory.

43.6.19.2 Descriptor Memory Mapping

Three descriptor views are available. Descriptor view 0 is used when the pixel or data stream is packed. Descriptor view 1 is used for YCbCr semi-planar pixel stream. Descriptor view 2 is used for YCbCr planar pixel stream.

43.6.20 Histogram Module

For each possible pixel value, the histogram counts the number of times the value was encountered in the current image. RGGB Bayer, raw data or luminance histogram are available. There are 512 entries in the histogram entries, and each histogram bin can count up to 2^20 data. As the table entries are limited, each bin is actually a range, i.e., least significant bits are ignored. A write to ISC_CTRLEN.HISREQ initiates a new histogram. The counting operation ends when ISC_INTSR.HISDONE is set. At that time, a software or hardware dma transfer copies the table from the interface to the internal or external memory. To clear the table content (for a new operation), use ISC_CTRLEN.HISCLR. An automatic clear (reset after read) is available when ISC_HIS_CFG.RAR is set. In that case, as soon as the data is read from the table, the table entry is cleared.

				FIELD		HISREQ	UPPRO	CAPTURE
Access				R		R	R	R
Reset				0		0	0	0

Bit 31 – SIP Synchronization In Progress

Value	Description
0	The double domain synchronization is terminated.
1	The double domain synchronization is in progress.

Bit 4 – FIELD Field Status (only relevant when the video stream is interlaced)

Value	Description
0	The current field/segment is a top field
1	The current field/segment is a bottom field.

Bit 2 – HISREQ Histogram Request Pending

Value	Description
0	There is no histogram pending request.
1	Indicates that the histogram request is still pending.

Bit 1 – UPPRO Profile Update Pending

Value	Description
0	There is no profile update pending request.
1	Indicates that the profile update request is still pending.

Bit 0 – CAPTURE Capture Pending

Value	Description
0	Capture mode is disabled.
1	Capture is pending.

43.7.4 ISC Parallel Front End Configuration 0 Register

Name: ISC_PFE_CFG0
Offset: 0x0C
Reset: 0x00000000
Property: Read/Write

Reset	0	0	0	0	0	0	0	0

Bit 31 – REP Up Multiply with Replication

Value	Description
0	Unused bits are stuck at 0.
1	Unused bits are copied from MSB.

Bits 30:28 – BPS[2:0] Bits Per Sample

Value	Name	Description
0	TWELVE	12-bit input
1	ELEVEN	11-bit input
2	TEN	10-bit input
3	NINE	9-bit input
4	EIGHT	8-bit input
5	FORTY	40-bit input (used for MIPI formats up to forty bits per pixel)

Bit 27 – CCIR_REP CCIR Replication

Value	Description
0	Unused bits are stuck at 0.
1	Unused bits are copied from MSB.

Bits 23:16 – SKIPCNT[7:0] Frame Skipping Counter

Bit 14 – MIPI MIPI Interface Connection

Value	Description
0	Input data are coming from the physical parallel interface.
1	Input data are coming from the physical MIPI interface.

Bit 13 – ROWEN Row Cropping Enable

Value	Description
0	Row Cropping is disabled.
1	Row Cropping is enabled.

Bit 12 – COLEN Column Cropping Enable

Value	Description
0	Column Cropping is disabled.
1	Column Cropping is enabled.

Bit 11 – CCIR10_8N CCIR 10 bits or 8 bits

Value	Description
0	8-bit mode.
1	10-bit mode.

Bit 10 – CCIR_CRC CCIR656 CRC Decoder

Value	Description
0	Embedded CRC is discarded.
1	Embedded CRC is decoded.

Bit 9 – CCIR656 CCIR656 input mode

Value	Description
0	HSYNC and VSYNC signals are used to synchronize the input stream.
1	Embedded synchronization is used.

Bit 8 – GATED Gated input clock

Value	Description
0	The external pixel clock is free running.
1	The external pixel clock is gated.

Bit 7 – CONT Continuous Acquisition

Value	Description
0	Single Shot mode.
1	Video mode.

Bits 6:4 – MODE[2:0] Parallel Front End Mode

Value	Name	Description
0	PROGRESSIVE	Video source is progressive.
1	DF_TOP	Video source is interlaced, two fields are captured starting with top field.
2	DF_BOTTOM	Video source is interlaced, two fields are captured starting with bottom field.
3	DF_IMMEDIATE	Video source is interlaced, two fields are captured immediately.
4	SF_TOP	Video source is interlaced, one field is captured starting with the top field.
5	SF_BOTTOM	Video source is interlaced, one field is captured starting with the bottom field.
6	SF_IMMEDIATE	Video source is interlaced, one field is captured starting immediately.

Bit 3 – FPOL Field Polarity

Value	Description
0	Top field is sampled when F value is 0; Bottom field is sampled when F value is 1.
1	Top field is sampled when F value is 1; Bottom field is sampled when F value is 0.

Bit 2 – PPOL Pixel Clock Polarity

Value	Description
0	The pixel stream is sampled on the rising edge of the pixel clock.
1	The pixel stream is sampled on the falling edge of the pixel clock.

Bit 1 – VPOL Vertical Synchronization Polarity

Value	Description
0	VSYNC signal is active high, i.e. valid pixels are sampled when VSYNC is asserted.
1	VSYNC signal is active low, i.e. valid pixels are sampled when VSYNC is deasserted.

Bit 0 – HPOL Horizontal Synchronization Polarity

Value	Description
0	HSYNC signal is active high, i.e. valid pixels are sampled when HSYNC is asserted.
1	HSYNC signal is active low, i.e. valid pixels are sampled when HSYNC is deasserted.

43.7.5 ISC Parallel Front End Configuration 1 Register

Name: ISC_PFE_CFG1
Offset: 0x10
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24

Bit 20 – RERR Read Channel Error Interrupt Mask

Bit 16 – WERR Write Channel Error Interrupt Mask

Bit 13 – HISCLR Histogram Clear Interrupt Mask

Bit 12 – HISDONE Histogram Completed Interrupt Mask

Bit 9 – LDONE DMA List Done Interrupt Mask

Bit 8 – DDONE DMA Done Interrupt Mask

Bit 5 – DIS Disable Completed Interrupt Mask

Bit 4 – SWRST Software Reset Completed Interrupt Mask

Bit 1 – HD Horizontal Synchronization Detection Interrupt Mask

Bit 0 – VD Vertical Synchronization Detection Interrupt Mask

43.7.14 ISC Interrupt Status Register

Name: ISC_INTSR
Offset: 0x34
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
			GFOV	CCIRERR	HDTO	VDTO	DAOV	VFPOV
Access			R	R	R	R	R	R
Reset			0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
				RERR		WERRID[1:0]		WERR
Access				R		R	R	R
Reset				0		0	0	0

Bit	15	14	13	12	11	10	9	8
			HISCLR	HISDONE			LDONE	DDONE
Access			R	R			R	R
Reset			0	0			0	0

Bit	7	6	5	4	3	2	1	0
			DIS	SWRST			HD	VD
Access			R	R			R	R
Reset			0	0			0	0

Bit 29 – GFOV FIFO Overflow Interrupt (relevant if MIPI interface is not selected) (cleared on read)

Value	Description
0	No FIFO overflow detected since the last read of the Interrupt Status register.
1	A FIFO overflow has been detected.

Bit 28 – CCIRERR CCIR Decoder Error Interrupt (cleared on read)

Value	Description
0	No CCIR CRC error detected since the last read of the Interrupt Status register.
1	A CCIR CRC error has been detected.

Bit 27 – HDTO Horizontal Synchronization Timeout Interrupt (cleared on read)

Value	Description
0	A horizontal synchronization is detected.
1	No horizontal synchronization is detected.

Bit 26 – VDTO Vertical Synchronization Timeout Interrupt (cleared on read)

Value	Description
0	A vertical synchronization is detected.
1	No vertical synchronization is detected.

Bit 25 – DAOV Data Overflow Interrupt (cleared on read)

Value	Description
0	No data overflow error occurred since the last reset of the Interrupt Status register.
1	A data overflow occurred.

Bit 24 – VFPOV Vertical Front Porch Overflow Interrupt (cleared on read)

Value	Description
0	No vertical front porch error occurred since the last read of the Interrupt Status register.

Value	Description
1	The vertical synchronization has been detected but the DMA channel is still busy.

Bit 20 – RERR Read Channel Error Interrupt (cleared on read)

Value	Description
0	No read channel error since the last read of the Interrupt Status register.
1	A read channel error occurred when the ISC read the descriptor.

Bits 18:17 – WERRID[1:0] Write Channel Error Identifier (cleared on read)

Value	Name	Description
0	CH0	An error occurred for Channel 0 (RAW/RGB/Y)
1	CH1	An error occurred for Channel 1 (CbCr/Cb)
2	CH2	An error occurred for Channel 2 (Cr)
3	WB	Write back channel error

Bit 16 – WERR Write Channel Error Interrupt (cleared on read)

Value	Description
0	No write channel error since the last read of the Interrupt Status register.
1	A write channel error occurred.

Bit 13 – HISCLR Histogram Clear Interrupt (cleared on read)

Value	Description
0	No Histogram Clear Interrupt has been raised since the last read of the Interrupt Status register.
1	The Histogram Clear Interrupt has occurred.

Bit 12 – HISDONE Histogram Completed Interrupt (cleared on read)

Value	Description
0	No Histogram Completed Interrupt has been raised since the last read of the Interrupt Status register.
1	The Histogram Completed Interrupt has occurred.

Bit 9 – LDONE DMA List Done Interrupt (cleared on read)

Value	Description
0	No DMA List Done Interrupt has occurred since the last read of the Interrupt Status register.
1	The DMA List Done Interrupt has occurred.

Bit 8 – DDONE DMA Done Interrupt (cleared on read)

Value	Description
0	No DMA Transfer Done Interrupt has occurred since the last read of the Interrupt Status register.
1	The DMA Transfer Done Interrupt has occurred.

Bit 5 – DIS Disable Completed Interrupt (cleared on read)

Value	Description
0	The disable has not occurred since the last read of the Interrupt Status register.
1	The disable has completed.

Bit 4 – SWRST Software Reset Completed Interrupt (cleared on read)

Value	Description
0	No software reset completion since the last read of the Interrupt Status register.
1	The software reset has completed.

Bit 1 – HD Horizontal Synchronization Detected Interrupt (cleared on read)

Value	Description
0	No horizontal synchronization detection since the last read of the Interrupt Status register.
1	A horizontal synchronization has been detected.

Bit 0 – VD Vertical Synchronization Detected Interrupt (cleared on read)

Value	Description
0	No vertical synchronization detection since the last read of the Interrupt Status register.
1	A vertical synchronization has been detected.

43.7.15 ISC Defective Pixel Control Register

Name: ISC_DPC_CTRL
Offset: 0x40
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
						BLCEN	GDCEN	DPCEN
Access						R/W	R/W	R/W
Reset						0	0	0

Bit 2 – BLCEN Black Level Correction Enable

Value	Description
0	Black level correction is disabled.
1	Black level correction is enabled.

Bit 1 – GDCEN Green Disparity Correction Enable

Value	Description
0	Green disparity correction is disabled.
1	Green disparity correction is enabled.

Bit 0 – DPCEN Defective Pixel Correction Enable

Value	Description
0	Defective pixel correction is disabled.
1	Defective pixel correction is enabled.

43.7.16 ISC Defective Pixel Configuration Register

Name: ISC_DPC_CFG
Offset: 0x44
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
	BLOFST[8:1]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	BLOFST[0]	GDCCLP[2:0]					RE_MODE	ND_MODE
Access	R/W	R/W	R/W	R/W			R/W	R/W
Reset	0	0	0	0			0	0

Bit	15	14	13	12	11	10	9	8
		TA_ENABLE	TC_ENABLE	TM_ENABLE				
Access		R/W	R/W	R/W				
Reset		0	0	0				

Bit	7	6	5	4	3	2	1	0
				EITPOL			BAYCFG[1:0]	
Access				R/W			R/W	R/W
Reset				0			0	0

Bits 31:23 – BLOFST[8:0] Black Level Offset Value
BLOFST is the default constant value subtracted from the incoming stream. The value is unsigned, 0:8:0 value.

Bits 22:20 – GDCCLP[2:0] Green Disparity Clipping Value
Green Disparity Clipping is performed between [$-2^{GDCCLP+1}$, $-2^{GDCCLP+1}-1$]

Bit 17 – RE_MODE Replacement Algorithm

Value	Description
0	Median pixel is used.
1	Average pixel is used.

Bit 16 – ND_MODE Noise Detection Mode

Value	Description
0	At least one detector flag is necessary to trigger the correction.
1	All detector flags are required to trigger the correction.

Bit 14 – TA_ENABLE Average Threshold Enable

Value	Description
0	Average detector is disabled.
1	Average detector is enabled.

Bit 13 – TC_ENABLE Closest Pixels Threshold Enable

Value	Description
0	Closest Pixels detector is disabled.
1	Closest Pixels detector is enabled.

Bit 12 – TM_ENABLE Median Threshold Enable

Value	Description
0	Median detector is disabled.
1	Median detector is enabled.

Bit 4 – EITPOL Edge Interpolation

Value	Description
0	No edge interpolation is performed.
1	Edge interpolation is performed.

Bits 1:0 – BAYCFG[1:0] Color Filter Array Pattern

Value	Name	Description
0	GRGR	Starting row configuration is G R G R (red row)
1	RGRG	Starting row configuration is R G R G (red row)
2	GBGB	Starting row configuration is G B G B (blue row)
3	BGBG	Starting row configuration is B G B G (blue row)

				BIPART	RENABLE	GENABLE	BENABLE	ENABLE
Access				R/W	R/W	R/W	R/W	R/W
Reset				0	0	0	0	0

Bit 4 – BIPART Bipartite Table Configuration

Value	Description
0	Bipartite table is disabled. There are 64 points of interpolation from 0 to 4095.
1	Bipartite table is enabled. There are 32 points of interpolation (spacing is 8) from 0 to 255, then there are 30 points of interpolation from 256 to 4095.

Bit 3 – RENABLE Gamma Correction Enable for R Channel

Value	Description
0	12-bit to 10-bit compression is performed skipping two bits.
1	Piecewise interpolation is used to perform 12-bit to 10-bit compression for the red channel.

Bit 2 – GENABLE Gamma Correction Enable for G Channel

Value	Description
0	12-bit to 10-bit compression is performed skipping two bits.
1	Piecewise interpolation is used to perform 12-bit to 10-bit compression for the green channel.

Bit 1 – BENABLE Gamma Correction Enable for B Channel

Value	Description
0	12-bit to 10-bit compression is performed skipping two bits.
1	Piecewise interpolation is used to perform 12-bit to 10-bit compression for the blue channel.

Bit 0 – ENABLE Gamma Correction Enable

Value	Description
0	Gamma correction is disabled.
1	Gamma correction is enabled.

Bits 31:28 – FLMAX[3:0] Flush Latency Maximum
Defines the maximum number of valid cycles between two lines when the pipeline generates lines.

Bits 27:24 – FLMIN[3:0] Flush Latency Minimum
Defines the minimum number of valid cycles between two lines.

Bits 11:8 – OFFSET[3:0] Resampling Default Phase
Defines the phase initialization of the filter.

Bit 4 – TAP2 Bilinear Interpolation

Value	Description
0	Custom tap values are used (see ISC_VXS_TAP10PHI).
1	Bilinear interpolation is used.

Bits 1:0 – FILTCFG[1:0] Vertical Filter Initial Configuration
Defines how the resampling filter will be initialized. Use value 1 for RGB interpolated pixel stream.

43.7.46 ISC HXS Configuration Register

Bit	7	6	5	4	3	2	1	0
			MIPI420	FILTER				ENABLE
Access			R/W	R/W				R/W
Reset			0	0				0

Bit 5 – MIPI420 MIPI YUV 420 8-bpp or 10-bpp Even Odd Splitter

Value	Description
0	Normal mode.
1	When the MIPI interface is selected and the source format is YUV 420 RMS (recommended memory storage), the sub420 submodule routes data lanes depending on the parity of the line received (odd or even).

Bit 4 – FILTER Interlaced or Progressive Chrominance Filter

Value	Description
0	Progressive filter {0.5, 0.5}.
1	Field-dependent filter, top field filter is {0.75, 0.25}, bottom field filter is {0.25, 0.75}.

Bit 0 – ENABLE 4:2:2 to 4:2:0 Vertical Subsampling Filter Enable (Center Aligned)

Value	Description
0	Subsampler disabled.
1	Subsampler enabled.

43.7.67 ISC Rounding, Limiting and Packing Configuration Register

Name: ISC_RLP_CFG
Offset: 0x4F4
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset

	ALPHA[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0
Bit	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	YMODE[1:0]		LSH	REP	MODE[3:0]			
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 15:8 – ALPHA[7:0] Alpha Value for Alpha-enabled RGB Mode
This field is relevant for ARGB444, ARGB555 and ARGB32 pixel formats.

Bits 7:6 – YMODE[1:0] YCbCr Memory Mapping Configuration Mode
YMODE is only available for YCYC and YCYC_Limited modes.

Value	Name	Description
0	RLP_YCBYCR	Byte 0 is Cr, Byte 1 is Y(n), Byte 2 is Cb, Byte 3 is Y(n+1)
1	RLP_YCRYCB	Byte 0 is Cb, Byte 1 is Y(n), Byte 2 is Cb, Byte 3 is Y(n+1)
2	RLP_CBYCRY	Byte 0 is Y(n), Byte 1 is Cr, Byte 2 is Y(n+1), Byte 3 is Cb
3	RLP_CRYCBY	Byte 0 is Y (n), Byte 1 is Cb, Byte 2 is Y(n+1), Byte 3 is Cr

Bit 5 – LSH Logical Left Shift for Pixel to 16-bit Container Mapping

Value	Description
0	Logical left shift is disabled.
1	Pixel value is left-justified in a 16-bit container.

Bit 4 – REP Pixel Expansion with Replication Logic

Value	Description
0	Replication is disabled.
1	Replication is enabled.

Bits 3:0 – MODE[3:0] Rounding, Limiting and Packing Mode

Value	Name	Description
0	DAT8	8-bit data
1	DAT9	9-bit data
2	DAT10	10-bit data
3	DAT11	11-bit data
4	DAT12	12-bit data

Value	Name	Description
5	DATY8	8-bit luminance only
6	DATY10	10-bit luminance only
7	ARGB444	12-bit RGB+4-bit Alpha (MSB)
8	ARGB555	15-bit RGB+1-bit Alpha (MSB)
9	RGB565	16-bit RGB
10	ARGB32	24-bits RGB mode+8-bit Alpha
11	YYCC	YCbCr mode (full range, [0–255])
12	YYCC_LIMITED	YCbCr mode (limited range)
13	YCYC	Y(n+1)CbY(n)Cr 422 interleaved full range per component 8-bit [0–255]
14	YCYC_LIMITED	Y(n+1)CbY(n)Cr 422 interleaved limited range per component 8-bit
15	BYPASS	32-bit input is sampled and written to the rlp output port. Select this mode for MIPI RMS mode.

43.7.68 ISC Histogram Control Register

Name: ISC_HIS_CTRL

			BAYSEL[1:0]			MODE[2:0]		
Access			R/W	R/W		R/W	R/W	R/W
Reset			0	0		0	0	0

Bit 8 – RAR Histogram Reset After Read

Value	Description
0	Reset after read mode is disabled.
1	Reset after read mode is enabled.

Bits 5:4 – BAYSEL[1:0] Bayer Color Component Selection

Value	Name	Description
0	GRGR	Starting row configuration is G R G R (red row)
1	RGRG	Starting row configuration is R G R G (red row)
2	GBGB	Starting row configuration is G B G B (blue row)
3	BGBG	Starting row configuration is B G B G (blue row)

Bits 2:0 – MODE[2:0] Histogram Operating Mode

Value	Name	Description
0	GR	Gr sampling
1	R	R sampling
2	GB	Gb sampling
3	B	B sampling
4	Y	Luminance-only mode
5	RAW	Raw sampling
6	YCCIR656	Luminance only with CCIR656 10-bit or 8-bit mode

43.7.70 ISC DMA Configuration Register

Name: ISC_DCFG
Offset: 0x51C
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access

Reset	0	0	0	0		0	0	0

Bit 7 – DONE Descriptor Processing Status
This bit appears only in the descriptor located in memory and can be used only if WB (Write Back) is set.

Value	Description
0	Descriptor not processed yet.
1	Descriptor processed.

Bit 6 – FIELD Value of Captured Frame Field Signal
This bit is only relevant for interlaced content. It appears only in the descriptor located in memory and can be used only if WB (Write Back) is set.

Value	Description
0	Field value is 0.
1	Field value is 1.

Bit 5 – WB Write Back Operation Enable

Value	Description
0	Write Back operation is skipped.
1	Write Back operation is performed.

Bit 4 – IE Interrupt Enable

Value	Description
0	DMA Done interrupt is generated.
1	DMA Done interrupt is not set.

Bits 2:1 – DVIEW[1:0] Descriptor View

Value	Name	Description
0	PACKED	Address {0} Stride {0} are updated
1	SEMIPLANAR	Address {0,1} Stride {0,1} are updated
2	PLANAR	Address {0,1,2} Stride {0,1,2} are updated

Bit 0 – DE Descriptor Enable

Value	Description
0	Descriptor disabled.
1	Descriptor enabled.

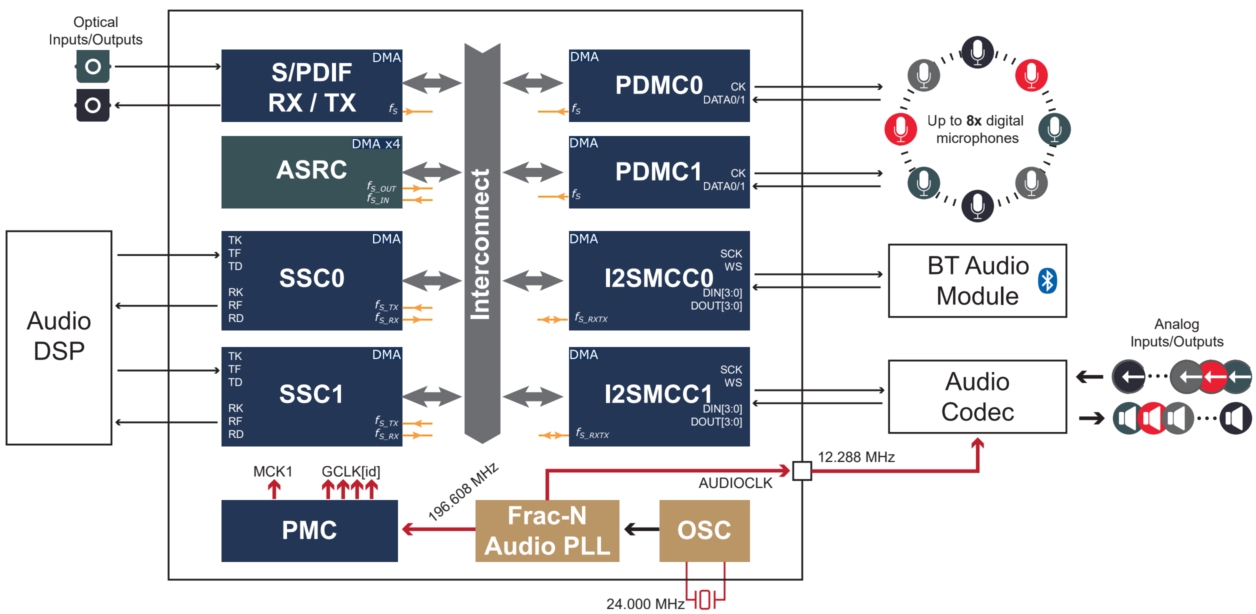
44. AUDIO SUBSYSTEM

44.1 Block Diagram

Figure 44-1. Audio Subsystem Block Diagram Example



44.2 Components

The audio subsystem is made of the following components. Unless otherwise specified, all are designed to handle audio sample rates up to 192 kHz.

- 2x Synchronous Serial Controller (SSC)
  - The maximum bit clock (TK or RK) speed is 25 MHz in Host or Client mode on both the receiver and the transmitter.
  - As an example, in TDM mode, this corresponds to up to 4x 32-bit channels at 192 kHz, or up to 8x 32-bit channels at 96 kHz.
- 2x Inter-IC Sound Multi Channel Controller (I2SMCC)
  - The maximum bit clock (I2SMCCx_SCK) speed is 12.5 MHz in both Host and Client modes.
  - In TDM256 mode, this corresponds to 8x 32-bit channels at 48 kHz.
  - In 4x data lines Stereo mode, up to 8x 32-bit channels at 192 kHz are supported.
- 2x Pulse Density Microphone Controller (PDMC)
  - Support of up to 8x microphones on 4 data lines with 48 kHz sampling rate
- 1x Sony/Philips Digital Interface Receiver (SPDIFRX)
  - Support of sample rate up to 192 kHz with $f_{GCLK} \geq 150$ MHz
- 1x Sony/Philips Digital Interface Transmitter (SPDIFTX)
  - Support of sample rate up to 192 kHz stereo with $f_{GCLK} \geq 24.5476$ MHz
- 1x low-jitter audio PLL with one dedicated AUDIOCLK output pin
- 1x Asynchronous Sample Rate Converter (ASRC) with 4 stereo channels
  - Supporting up to 4 independent conversion rates

44.3 Product Dependencies

44.3.1 Clocks

Audio peripherals are part of the APB Client (APS) matrix, clocked by MCK1. Their peripheral clocks and generic clocks are controlled in the PMC.

To generate audio frequencies with high accuracy, the device embeds a fractional audio PLL that can serve both the internal (GCLK generation) and external needs (MCK generation on external audio components).

The ASRC receives the frame synchronization signals from all audio peripherals so it can adapt its internal DSP filters to the (unknown) rate of the interface it is connected to, on both its input and output sides. Therefore, converting the audio sample rate from one interface to another can be done with no knowledge of these rates.

44.3.2 Interrupts

Refer to the table Peripheral Identifiers.

44.3.3 Reset

Audio peripherals are connected to the processor and peripherals reset line.

44.3.4 I/Os

Audio I/Os are multiplexed on GPIOs with various power supplies. For the applicable I/O type and power supply, refer to the table Pin Description.

44.4 Special Functions in SFR/SFRBU

None.

45. Inter-IC Sound Multi-Channel Controller (I2SMCC)

45.1 Description

The Inter-IC Sound Multi-Channel Controller (I2SMCC) provides an 11-wire, bidirectional, synchronous, digital audio link to external audio devices: I2SMCC_DIN3..0, I2SMCC_DOUT3..0, I2SMCC_WS, I2SMCC_CK, and I2SMCC_MCK pins.

The I2SMCC complies with the Inter-IC Sound (I^2S) bus specification and supports a Time Division Multiplexed (TDM) interface with external multi-channel audio codecs.

The I2SMCC consists of a receiver, a transmitter and a common clock generator that can be enabled separately to provide Host, Client or Controller modes with receiver and/or transmitter active.

DMA Controller channels, separate for the receiver and for the transmitter, allow a continuous high bit rate data transfer without processor intervention to the following:

- Audio CODECs in Host, Client, or Controller mode
- Stereo DAC or ADC through a dedicated I^2S serial interface
- Multi-channel or multiple stereo DACs or ADCs, using the TDM format

The I2SMCC uses a single DMA Controller channel for all audio channels.

The 8- and 16-bit compact stereo formats reduce the required DMA Controller bandwidth by transferring the left and right samples within the same data word.

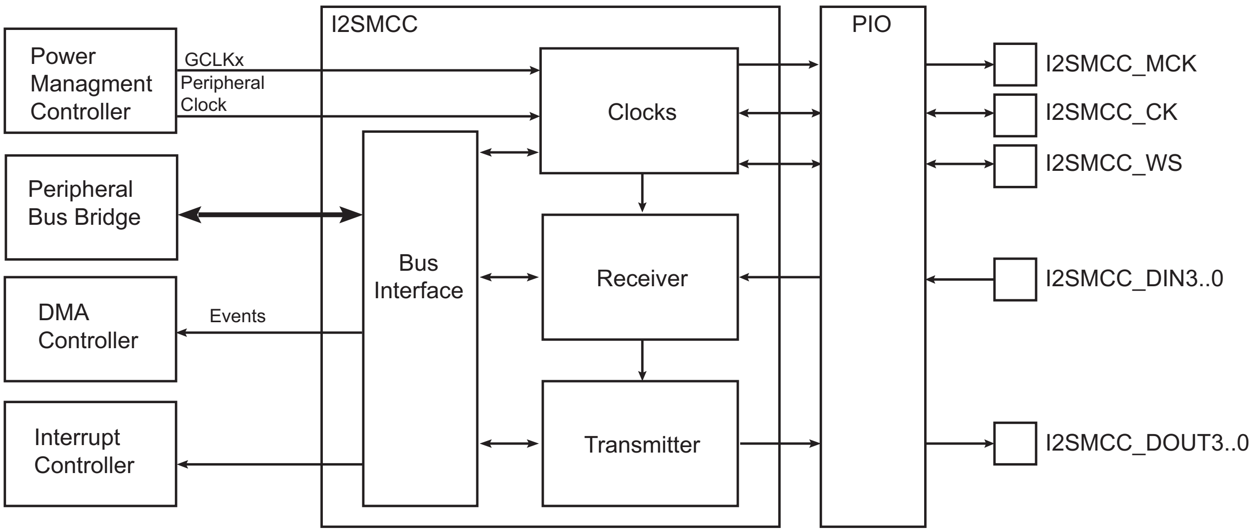
In Host mode, the I2SMCC can produce a 16 f_s to 1024 f_s host clock that provides an over-sampling clock to an external audio codec or digital signal processor (DSP).

45.2 Embedded Characteristics

- Compliant with Inter-IC Sound (I^2S) Bus Specification
- Host, Client, and Controller Modes
  - Client: Data received/transmitted
  - Host: Data received/transmitted and clocks generated
  - Controller: Clocks generated
- FIFO
- Individual Enable and Disable of Receiver, Transmitter and Clocks
- Configurable Clock Generator Common to Receiver and Transmitter
  - Suitable for a wide range of sample frequencies (f_s), including 32 kHz, 44.1 kHz, 48 kHz, 88.2 kHz, 96 kHz, and 192 kHz
  - 16 f_s to 1024 f_s host clock generated for external oversampling data converters
- Support for Multiple Data Formats
  - 32-, 24-, 20-, 18-, 16-, and 8-bit mono or stereo format
  - 16- and 8-bit compact stereo format, with left and right samples packed in the same word to reduce data transfers
- Support for Multiple Data Frame Formats
  - 2-channel I^2S with word select
  - 1- to 8-channel Time Division Multiplexed (TDM) with frame synchronization
- DMA Controller Interfaces the Receiver and Transmitter to Reduce Processor Overhead
- Smart Holding Registers Management to Avoid Audio Channel Mix After Overrun or Underrun
- Functional Safety Monitors and Reports
  - Internal sequencer integrity check reports
  - Register write protection

45.3 Block Diagram

Figure 45-1. I2SMCC Block Diagram



45.4 I/O Lines Description

Table 45-1. I/O Lines Description

Pin Name	Pin Description	Type
I2SMCC_MCK	Host Clock	Output
I2SMCC_CK	Serial Clock	Input/Output
I2SMCC_WS	I^2S Word Select or TDM Frame Synchronization	Input/Output
I2SMCC_DIN3..0	Serial Data Inputs	Input
I2SMCC_DOUT3..0	Serial Data Outputs	Output

45.5 Product Dependencies

To use the I2SMCC, other parts of the system must be configured correctly, as described below.

45.5.1 I/O Lines

The I2SMCC pins may be multiplexed with I/O Controller lines. The user must first program the PIO Controller to assign the required I2SMCC pins to their peripheral function. If the I2SMCC I/O lines are not used by the application, they can be used for other purposes by the PIO Controller. The user must enable the I2SMCC inputs and outputs that are used.

45.5.2 Power Management

If the processor enters a Sleep mode that disables clocks used by the I2SMCC, the I2SMCC stops functioning and resumes operation after the system wakes up from Sleep mode.

45.5.3 Clocks

The I2SMCC runs from the peripheral clock and the generic clock (GCLK), both generated by the Power Management Controller (PMC). Prior to using the I2SMCC, the user must first program the PMC. The I^2S host and serial clock can be generated either from the peripheral clock or the generic clock.

In a similar way, the I2SMCC must be disabled before removing its clock source to avoid freezing it in an undefined state.

45.5.4 DMA Controller

The I2SMCC interfaces to the DMA Controller. Using the I2SMCC DMA functionality requires the DMA Controller to be programmed first.

45.5.5 Interrupt Sources

The I2SMCC interrupt line is connected to the Interrupt Controller. Using the I2SMCC interrupt requires the Interrupt Controller to be programmed first.

45.6 Functional Description

45.6.1 Initialization

The I2SMCC features a receiver, a transmitter and a clock generator for Host and Controller modes. Receiver and transmitter share the same serial clock and word select.

Before enabling the I2SMCC, the selected configuration must be written to the I2SMCC Mode Register A (I2SMCC_MRA). If I2SMCC_MRA.FORMAT is configured in one of the TDM formats, then the I2SMCC_MRA.NBCHAN and I2SMCC_MRA.TDMFS fields must also be written.

Once the I2SMCC_MRA has been written, the I2SMCC clock generator, receiver, and transmitter can be enabled by writing a ‘1’ to the CKEN, RXEN, and TXEN bits in the Control Register (I2SMCC_CR). The clock generator can be enabled alone in Controller mode to output clocks to the I2SMCC_MCK, I2SMCC_CK, and I2SMCC_WS pins. The clock generator must also be enabled if the receiver or the transmitter is enabled.

The clock generator, receiver, and transmitter can be disabled independently by writing a ‘1’ to I2SMCC_CR.CXDIS, I2SMCC_CR.RXDIS and/or I2SMCC_CR.TXDIS, respectively. Once requested to stop, they stop only when the transmission of the pending frame transmission is completed.

45.6.2 Basic Operation

The following description is only valid when the FIFO is disabled (I2SMCC_MRB.FIFOEN = 0).

When the FIFO is enabled, the flags RXLRDYx, RXRRDYx, TXLRDYx and TXRRDYx are not relevant in I2SMCC_ISRA. For details, refer to Holding Registers.

The receiver can be operated by reading the Receiver Holding register (I2SMCC_RHR) or the Receiver Holding Left x registers (I2SMCC_RHLxR) and the Receiver Holding Right x registers (I2SMCC_RHRxR), whenever the Receive Left x Ready (RXLRDYx) bit or the Receive Right Ready (RXRRDYx) bit in the Interrupt Status register A (I2SMCC_ISRA) is set. Successive values read from I2SMCC_RHR correspond to the samples from the first left audio channel to the last left audio channel enabled then from the first right audio channel to the last right audio channel enabled, or from channels 0 to I2SMCC_MRA.NBCHAN in TDM mode for the successive frames.

The transmitter can be operated by writing to the Transmitter Holding register (I2SMCC_THR) or the Transmitter Holding Left x registers (I2SMCC_THLxR) and the Transmitter Holding Right x registers (I2SMCC_THRxR), whenever the Transmit Left x Ready (TXLRDYx) bit or the Transmit Right x Ready (TXRRDYx) bit in the I2SMCC_ISRA is set. Successive values written to I2SMCC_THR correspond to the samples from the first left audio channel to the last left audio channel enabled, then from the first right audio channel to the last right audio channel enabled, or from channels 0 to I2SMCC_MRA.NBCHAN in TDM mode for the successive frames.

The RXLRDYx, RXRRDYx, TXLRDYx and TXRRDYx bits can be polled by reading the I2SMCC_ISRA.

The I2SMCC processor load can be reduced by enabling interrupt-driven operation. The RXLRDYx, RXRRDYx, TXLRDYx and/or TXRRDYx interrupt requests can be enabled by writing a ‘1’ to the corresponding bit in the Interrupt Enable Register A (I2SMCC_IERA). The interrupt service routine associated to the I2SMCC interrupt request is executed when at least one of the RXLRDYx, RXRRDYx, TXLRDYx and TXRRDYx status bits is set.

45.6.3 Host, Controller and Client Modes

In Host and Controller modes, the I2SMCC provides the host clock, the serial clock and the word select. I2SMCC_MCK, I2SMCC_CK, and I2SMCC_WS pins are outputs.

In Controller mode, the I2SMCC receiver and transmitter are disabled. Only the clocks are enabled and used by an external receiver and/or transmitter.

In Client mode, the I2SMCC receives the serial clock and the word select from an external host. I2SMCC_CK and I2SMCC_WS pins are inputs.

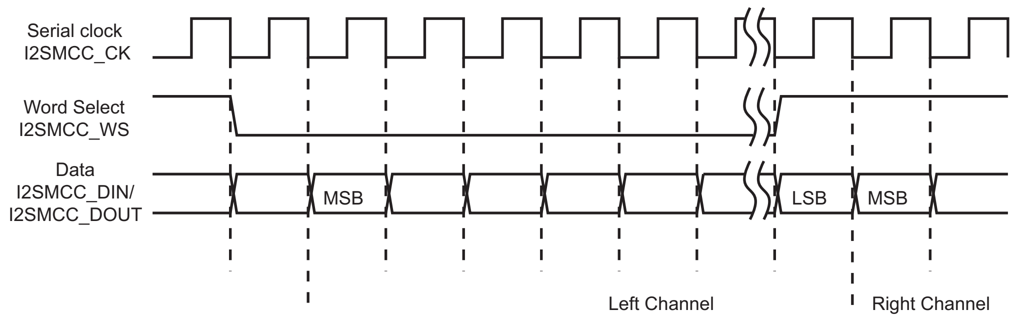
The mode is selected by writing I2SMCC_MRA.MODE. Since the MODE field changes the direction of the I2SMCC_WS and I2SSCK pins, the I2SMCC_MRA must only be written when the I2SMCC is stopped in order to avoid unwanted glitches on the I2SMCC_WS and I2SMCC_CK pins.

Note: When the Client mode is configured and TDM format is selected, the high level duration of the WS input signal can be one-slot (1 sample duration), half-slot or one-bit. The duration must be configured in I2SMCC_MRA.TDMFS (See I2SMCC_MRA).

45.6.4 I²S Reception and Transmission Sequence

As specified in the I²S protocol, data bits are left-justified in the word select time slot, with the MSB transmitted first, starting one clock period after the transition on the word select line.

Figure 45-2. I²S Reception and Transmission Sequence



Data bits are sent on the falling edge of the serial clock and sampled on the rising edge of the serial clock. The word select line indicates the channel in transmission, a low level for the left channel and a high level for the right channel.

The length of transmitted words can be chosen among 8, 16, 18, 20, 24, and 32 bits by writing I2SMCC_MRA.DATALENGTH.

If the time slot allows for more data bits than written in I2SMCC_MRA.DATALENGTH, zeroes are appended to the transmitted data word or extra received bits are discarded.

The slot length is defined in the following table.

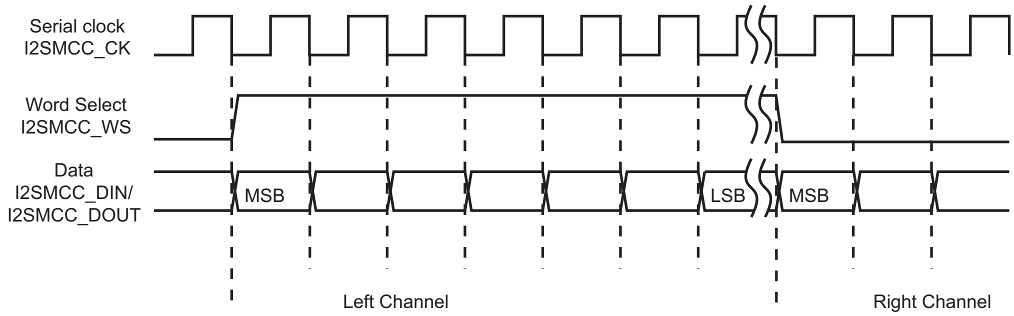
Table 45-2. Slot Length (I²S format)

I2SMCC_MRA.DATALENGTH	Word Length	Slot Length
0	32 bits	32
1	24 bits	32 if I2SMCC_MRA.IWS = 0 24 if I2SMCC_MRA.IWS = 1
2	20 bits	
3	18 bits	
4	16 bits	16
5	16 bits compact stereo	
6	8 bits	8
7	8 bits compact stereo	

45.6.5 Left-Justified Reception and Transmission Sequence

As specified in the I²S protocol, data bits are left-justified in the word select time slot, with the MSB transmitted first, starting at the same clock period as the transition on the word select line.

Figure 45-3. Left-Justified Reception and Transmission Sequence



Data bits are sent on the falling edge of the serial clock and sampled on the rising edge of the serial clock. The word select line indicates the channel in transmission, a low level for the right channel and a high level for the left channel.

The length of transmitted words can be chosen among 8, 16, 18, 20, 24, and 32 bits by writing I2SMCC_MRA.DATALENGTH.

If the time slot allows for more data bits than written in I2SMCC_MRA.DATALENGTH, zeroes are appended to the transmitted data word or extra received bits are discarded.

The Slot Length is defined in the following table.

Table 45-3. Slot Length (Left-Justified format)

I2SMCC_MRA.DATALENGTH	Word Length	Slot Length
0	32 bits	32
1	24 bits	32 if I2SMCC_MRA.IWS = 0 24 if I2SMCC_MRA.IWS = 1
2	20 bits	
3	18 bits	
4	16 bits	16
5	16 bits compact stereo	
6	8 bits	8
7	8 bits compact stereo	

45.6.6 TDM Reception and Transmission Sequence

In Time Division Multiplexed (TDM) format, one to eight data words are sent or received within each frame. As specified in the I^{2}S protocol, data bits are left-justified in the channel time slot, with the MSB transmitted first, starting one clock period after the transition on the word select line. Each time slot is 32 bits long.

Figure 45-4. TDM Reception and Transmission Sequence

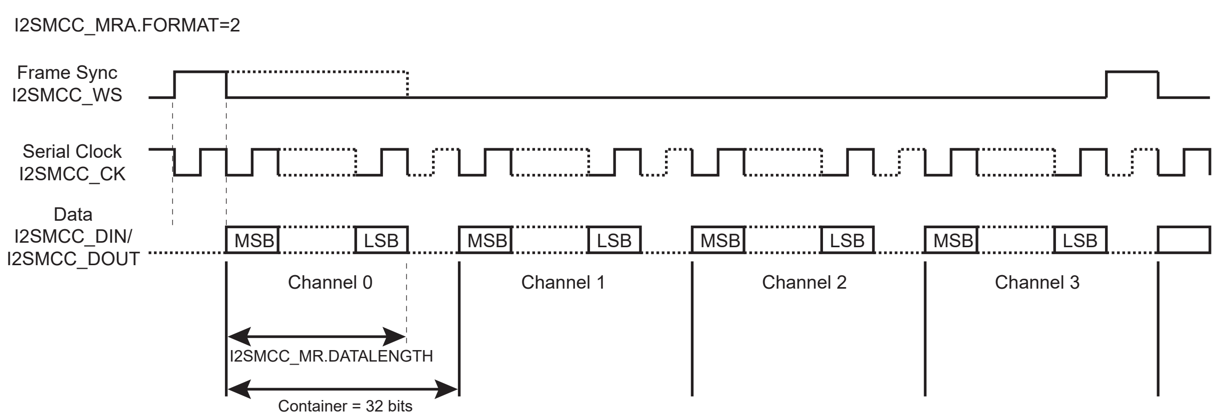


Figure 45-5. TDM Left-Justified Reception and Transmission Sequence

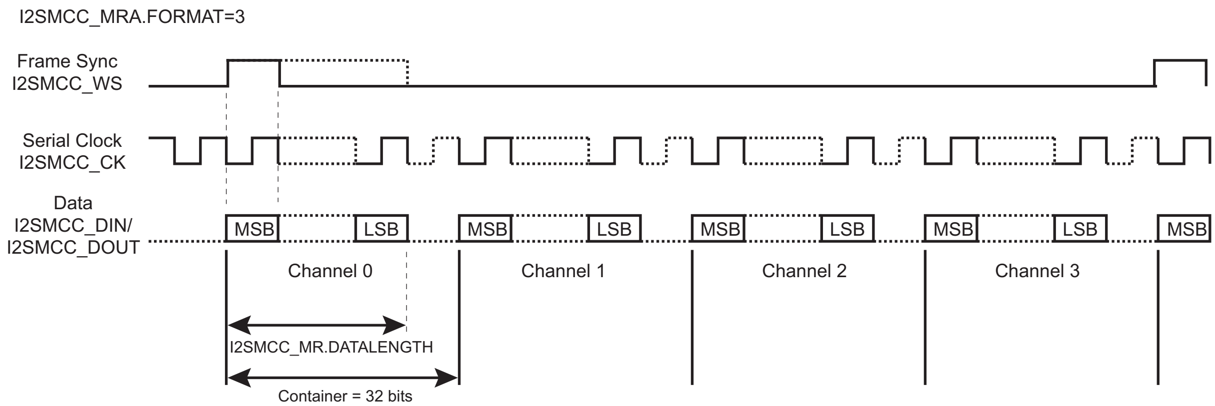


Data bits are sent on the falling edge of the serial clock and sampled on the rising edge of the serial clock. The I2SMCC_WS pin provides a frame synchronization signal, starting one I2SMCC_CK period before the MSB of channel 0.

The TDM format is selected when I2SMCC_MRA.FORMAT=2.

The TDM Left-Justified format is selected when I2SMCC_MRA.FORMAT=3.

The Frame Synchronization pulse can be either one I2SMCC_CK period, 16-bit I2SMCC_CK period (half time slot) or one 32-bit time slot. This selection is done by writing the I2SMCC_MRA.TDMFS bit.

The number of channels is selected by writing the I2SMCC_MRA.NBCHAN field.

The Frame Synchronization pulse set to 32-bit time slot with the number of channel set to 1 configuration is not supported.

The length of transmitted words can be chosen among 8, 16, 18, 20, 24, and 32 bits by writing the I2SMCC_MRA.DATALENGTH field.

If the time slot allows for more data bits than programmed in the I2SMCC_MRA.DATALENGTH field, zeroes are appended to the transmitted data word or extra received bits are discarded.

45.6.7 Serial Clock and Word Select Generation

The generation of clocks in the I2SMCC is described in the following figure.

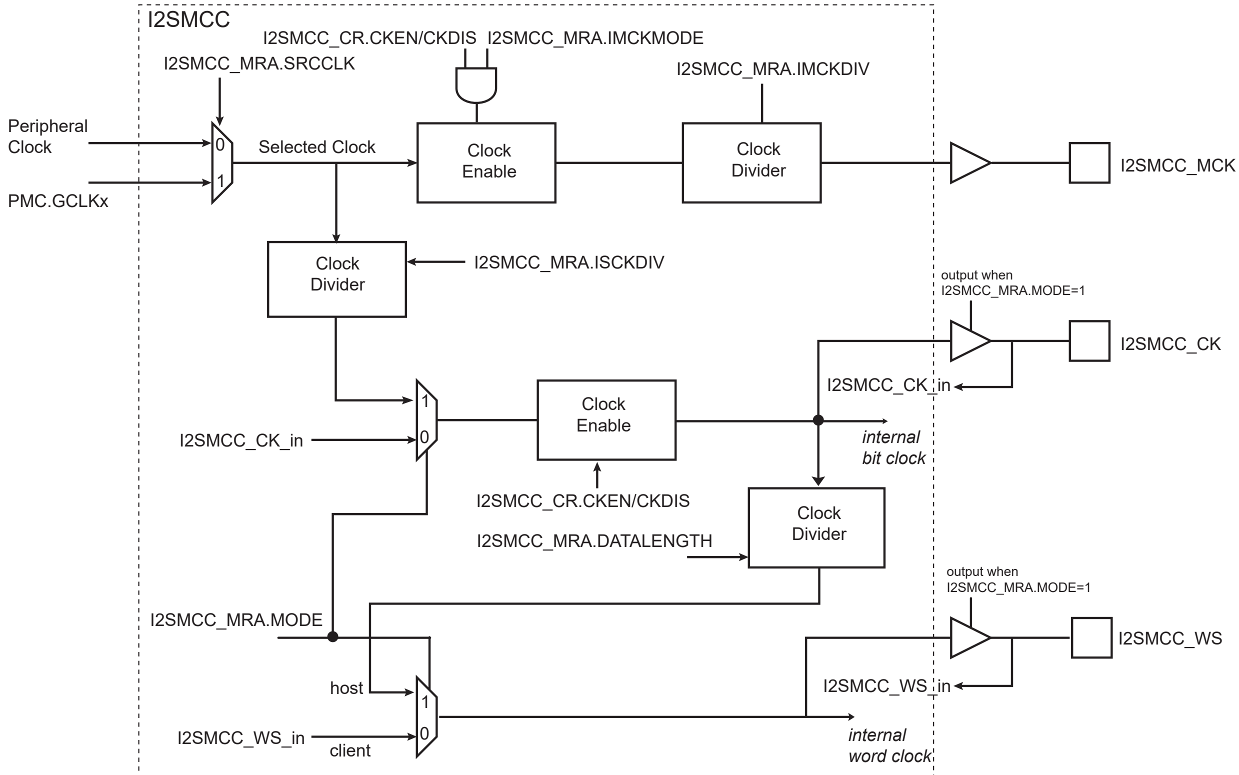
In Client mode, the word select clock is driven by an external host and the serial clock is driven by either an external host or the internal clock circuitry. I2SMCC_CK and I2SMCC_WS pins are inputs.

In Host mode, the user configures the host clock, serial clock, and word select clock through the I2SMCC_MRA. I2SMCC_MCK, I2SMCC_CK, and I2SMCC_WS pins are outputs, MCK and SCK frequencies are configured independently using IMCKDIV and ISCKDIV bits of I2SMCC_MRA, respectively.

If a host clock output is not required, the MCK clock is used as I2SMCC_CK by clearing I2SMCC_MRA.IMCKMODE.

The I2SMCC_WS pin is used as word select in I^{2}S format and as frame synchronization in TDM format, as described in I2S Reception and Transmission Sequence and TDM Reception and Transmission Sequence, respectively.

Figure 45-6. I2SMCC Clock Generation



45.6.8 Mono

When the Transmit Mono bit (TXMONO) in I2SMCC_MRA is set, data written to the left channel is duplicated to the right output channel. In TDM mode, with more than two channels numbered from 0, data written to the even-numbered channels is duplicated to the following odd-numbered channel. When TXMONO is set, TXRRDYx bits of I2SMCC_ISRA are always read as ‘0’ and the behavior of TXRUNFx bits is unchanged.

When the Receive Mono bit (RXMONO) in I2SMCC_MRA is set, data received from the left channel is duplicated to the right input channel. In TDM mode, with more than two channels numbered from 0, data received from the even-numbered channels is duplicated to the following odd-numbered channel. When RXMONO is set, the behavior of RXRRDYx and RXROVFx bits is unchanged.

45.6.9 Wire Configurations

By configuring I^2S or Left-Justified format, three wire configurations are available. The wire configuration is programmable by writing the field I2SMCC_MRA.WIRECFG. The available configurations are defined in the following table.

Table 45-4. Wire Configurations (I^2S and Left-Justified formats)

I2SMCC_MRA.WIRECFG	Configuration	Description
0	1 wire	I2SMCC_DIN0 and I2SMCC_DOUT0 are enabled. Only two I^2S channels are enabled (Left 0 and Right 0).
1	2 wires	I2SMCC_DIN1..0 and I2SMCC_DOUT1..0 are enabled. Only four I^2S channels are enabled (Left 0, Left1, Right 0 and Right 1).
2	4 wires	I2SMCC_DIN3..0 and I2SMCC_DOUT3..0 are enabled. All I^2S channels are enabled.

With the TDM or TDM Left-Justified format selected, four wire configurations are available. The wire configuration is selected via the WIRECFG bit. The available configurations are defined in the following table.

Table 45-5. Wire Configurations (TDM and TDM Left-Justified formats)

I2SMCC_MRA.WIRECFG	Configuration	Description
0	Wire 0	TDM communications take place on I2SMCC_DIN0 and I2SMCC_DOUT0 wires.
1	Wire 1	TDM communications take place on I2SMCC_DIN1 and I2SMCC_DOUT1 wires.
2	Wire 2	TDM communications take place on I2SMCC_DIN2 and I2SMCC_DOUT2 wires.
3	Wire 3	TDM communications take place on I2SMCC_DIN3 and I2SMCC_DOUT3 wires.

45.6.10 Holding Registers

The I2SMCC user interface includes two common holding registers—the Receive Holding Register (I2SMCC_RHR) and the Transmit Holding Register (I2SMCC_THR)— and dedicated holding registers per IO—the Receive Holding Left x Registers (I2SMCC_RHLxR), the Receive Holding Right x Registers (I2SMCC_RHRxR), the Transmit Holding Left x Registers (I2SMCC_THLxR) and the Transmit Holding Right x Registers (I2SMCC_THRxR). The common registers are used to access audio samples for all audio channels; the dedicated registers are used to access audio samples of one specific channel.

Access through common registers and dedicated registers must not be mixed. Only common registers or dedicated registers must be used.

The I2SMCC includes a Transmit (TX) FIFO and a Receive (RX) FIFO. Both FIFOs are only available through the common registers and must be enabled by setting the FIFOEN bit in the Mode register B (I2SMCC_MRB). When FIFOs are enabled, bits I2SMCC_ISRA.TXLRDYx and I2SMCC_ISRA.TXRRDYx must not be used. Bits TXFFRDY, TXFFEMP, RXFFRDY and RXFFFUL of the Interrupt Status register B (I2SMCC_ISRB) register provide the status of the FIFOs. These status bits are only available if the FIFOEN bit is set.

Each I^2S or TDM channel has its own register. The register depth depending on the configuration is available in the following table.

Table 45-6. Registers Depth

I2SMCC_MRA.FORMAT	I2SMCC_MRA.WIRECFG	I2SMCC_MRA.NBCHAN	Register Depth
0 or 1 (I^2S or LJ)	0	NA	4 words
	1		2 words
	2		1 word
2 or 3 (TDM or TDMLJ)	NA	0 or 1	4 words
		2 or 3	2 words
		4, 5, 6 or 7	1 word

45.6.10.1 Dedicated Registers

When a new data word is available in I2SMCC_RHLxR, the corresponding I2SMCC_ISRA.RXLRDYx is set. Reading I2SMCC_RHLxR clears this bit. When a new data word is available in I2SMCC_RHRxR, the corresponding I2SMCC_ISRA.RXRRDYx is set. Reading I2SMCC_RHRxR clears this bit.

A receive overrun condition occurs if a new data word becomes available for the left channel x before the previous data word has been read from I2SMCC_RHLxR. In this case, the Receive Left x Overrun bit (RXLOVFx) in I2SMCC_ISRA is set. Reading I2SMCC_ISRA clears this bit. A receive overrun condition occurs if a new data word becomes available for the right channel x before the previous data word has been read from I2SMCC_RHRxR. In this case, the Receive Right x Overrun bit (RXROVFx) in I2SMCC_ISRA is set. Reading I2SMCC_ISRA clears this bit.

When I2SMCC_THLxR is empty, I2SMCC_ISRA.TXLRDYx is set. Writing to I2SMCC_THLxR clears this bit. When I2SMCC_THRxR is empty, I2SMCC_ISRA.TXRRDYx is set. Writing to I2SMCC_THRxR clears this bit.

A transmit underrun condition occurs if a new data word needs to be transmitted before it has been written to I2SMCC_THLxR. In this case, the Transmit Left x Underrun (TXLUNFx) bit in I2SMCC_ISRA is set. Reading I2SMCC_ISRA clears this bit. A transmit underrun condition occurs if a new data word needs to be transmitted before it has been written to I2SMCC_THRxR. In this case, the Transmit Right x Underrun (TXRUNFx) bit in I2SMCC_ISRA is set. Reading I2SMCC_ISRA clears this bit.

In case of transmit underrun, if I2SMCC_MRA.TXSAME is '0', then a zero data word is transmitted. If I2SMCC_MRA.TXSAME is '1', then the previous data word for the current transmit channel number is transmitted.

Data words are right-justified in all dedicated registers (I2SMCC_RHLxR, I2SMCC_RHRxR, I2SMCC_THLxR and I2SMCC_THRxR). The 16-bit compact and 8-bit compact stereo data formats are not supported through dedicated registers.

In TDM or TDM Left-Justified mode, the dedicated left registers are used for even-numbered channels and the dedicated right registers are used for odd-numbered channels. The data of TDM channel 0 can be read through the I2SMCC_RHL0R and written through the I2SMCC_THL0R, the data of TDM channel 1 can be read through the I2SMCC_RHR0R and written through the I2SMCC_THR0R. Data read/write continues in this manner up to the data of TDM channel 6 read through the I2SMCC_RHL3R and written through the I2SMCC_THL3R and the data of TDM channel 7 read through the I2SMCC_RHR3R and written through the I2SMCC_THR3R.

45.6.10.2 Common Registers

The Receiver Holding Register (I2SMCC_RHR) and the Transmitter Holding Register (I2SMCC_THR) provide an access to all channels enabled through a single location.

When a new data word is available, the corresponding RXLRDYx bit or RXRRDYx bit in I2SMCC_ISRA is set. Reading I2SMCC_RHR clears this bit. In I^{2}S or Left-Justified mode with the Common register Access Mode bit (CRAMODE) of the Mode register B (I2SMCC_MRB) set to '0', consecutive access to I2SMCC_RHR reads first all the left channels enabled then all the right channels enabled. In I^{2}S or Left-Justified mode with the I2SMCC_MRB.CRAMODE bit set to '1', consecutive access to I2SMCC_RHR reads first the left and right channels of the first , then the left and right channels of the second I^{2}S enabled and so on until the last I^{2}S enabled. In TDM or TDM Left-Justified mode, consecutive access to I2SMCC_RHR reads the TDM channels enabled.

A receive overrun condition occurs if a new data word becomes available for the left channel x or right channel x before the previous data word has been read from I2SMCC_RHR. In this case, the corresponding RXLOVFx or RXROVFx bit in I2SMCC_ISRA is set. Reading I2SMCC_ISRA clears this bit.

When a data can be written in I2SMCC_THR, the corresponding TXLRDYx bit or TXRRDYx bit in I2SMCC_ISRA is set. Writing to I2SMCC_THR clears this bit. In I^{2}S or Left-Justified mode, with I2SMCC_MRB.CRAMODE set to '0', consecutive access to I2SMCC_THR writes first all the left channels enabled then all the right channels enabled. In I^{2}S or Left-Justified mode, with I2SMCC_MRB.CRAMODE set to '1', consecutive access to I2SMCC_THR writes first the left and right channels of the first I^{2}S enabled, then the left and right channels of the second I^{2}S enabled and continues in this manner until the last I^{2}S enabled. In TDM or TDM Left-Justified mode, consecutive access to I2SMCC_THR writes the TDM channels enabled.

A transmit underrun condition occurs if a new data word needs to be transmitted before it has been written to I2SMCC_THR. In this case, the corresponding TXLUNFx or TXRUNFx bit in I2SMCC_ISRA is set. Reading I2SMCC_ISRA clears this bit.

In case of transmit underrun, if the value of I2SMCC_MRA.TXSAME is '0', then a '0' is transmitted. If the value of I2SMCC_MRA.TXSAME is '1', then the previous data word for the current transmit channel number is transmitted.

After a transmit underrun, the data written in I2SMCC_THR is discarded to keep the left and right channels synchronized.

Data words are right-justified in the common registers (I2SMCC_RHR and I2SMCC_THR). For the 16-bit compact stereo data format, the left sample uses bits [15:0] and the right sample uses bits [31:16] of the same data word. For the 8-bit compact stereo data format, the left sample uses bits [7:0] and the right sample uses bits [15:8] of the same data word.

45.6.11 DMA Controller Operation

All receiver audio channels and all transmitter audio channels are each assigned to a single DMA Controller channel.

The DMA Controller reads from the I2SMCC_RHR and writes to the I2SMCC_THR for all audio channels successively.

The DMA Controller transfers may use 32-bit word, 16-bit halfword, or 8-bit byte depending on the value of the I2SMCC_MRA.DATALENGTH field.

The DMA chunk size field (DMACHUNK) of the Mode Register B(I2SMCC_MRB) should correspond to the DMA channel configuration. The supported chunk according to the configuration is available in the two tables below

Table 45-7. TX DMA Chunk Configurations

<table>
<tr><th>FORMAT</th><th>TXMONO</th><th>DATALENGTH</th><th>NBCHAN</th><th>DMACHUNK</th><th>Description</th></tr>
<tr><td rowspan="12">0 or 1
(I²S or LJ)</td><td rowspan="4">0
(Stereo)</td><td rowspan="8">0, 1, 2, 3, 4 or 6

45.6.12 Loop-back Mode

For debug purposes, the I2SMCC can be configured to loop back the transmitter to the receiver. Writing a ’1’ to the I2SMCC_MRA.RXLOOP bit internally connects I2SMCC_DOUTx to I2SMCC_DINx, so that the transmitted data is also received. Writing a ’0’ to I2SMCC_MRA.RXLOOP restores the normal behavior with independent receiver and transmitter. As for other changes to the receiver or transmitter configuration, the I2SMCC receiver and transmitter must be disabled before writing to I2SMCC_MRA to update I2SMCC_MRA.RXLOOP.

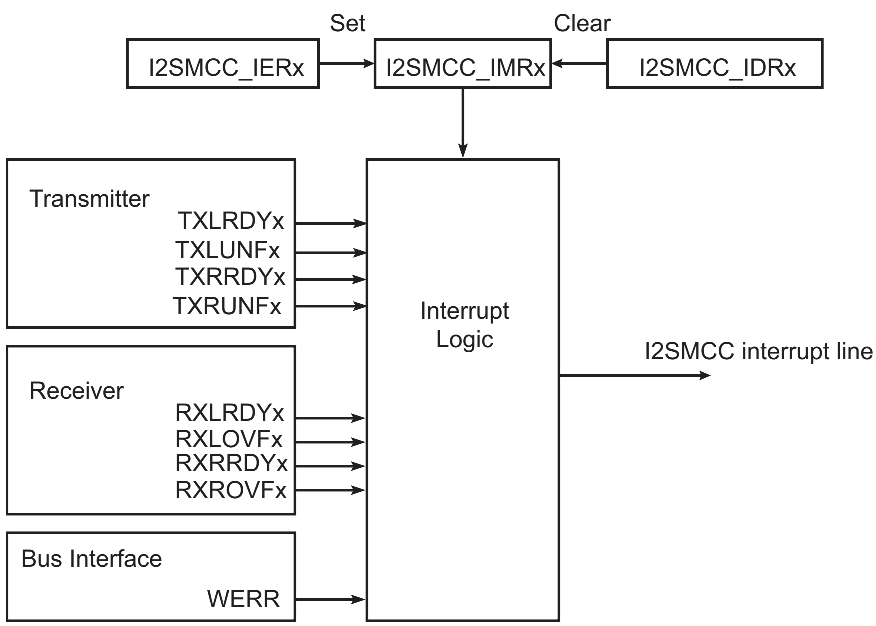
45.6.13 Interrupts

An I2SMCC interrupt request can be triggered whenever one or several of the following bits are set in I2SMCC_ISRA and/or I2SMCC_ISRB:

- Receive Left x Ready (RXLRDYx)
- Receive Right x Ready (RXRRDYx)
- Receive Left x Overrun (RXLOVFx)
- Receive Right x Overrun (RXROVFx)
- Transmit Left x Ready (TXLRDYx)
- Transmit Right x Ready (TXRRDYx)
- Transmit Left x Underrun (TXLUNFx)
- Transmit Right x Underrun (TXRUNFx)
- Write Error (WERR)
- Transmit FIFO Ready (TXFFRDY)
- Transmit FIFO Empty (TXFFEMP)
- Receive FIFO Ready (RXFFRDY)
- Receive FIFO Full (RXFFFUL)

The interrupt request is generated if the corresponding bit in the Interrupt Mask registers (I2SMCC_IMRA and I2SMCC_IMRB) is set. Bits in I2SMCC_IMRx are set by writing a '1' to the corresponding bit in I2SMCC_IERx and cleared by writing a '1' to the corresponding bit in I2SMCC_IDRx. The interrupt request remains active until the corresponding bit in I2SMCC_ISRx is cleared.

Figure 45-7. Interrupt Block Diagram



45.6.14 Register Write Protection

To prevent any single software error from corrupting I2SMCC behavior, certain registers in the address space can be write-protected by setting the Write Protection Configuration Enable (WPCFEN), Write Protection Interrupt Enable (WPITEN) and/or Write Protection Control Enable (WPCTEN) bit(s) in the Write Protection Mode register (I2SMCC_WPMR).

If a write access to the protected registers is detected, the Write Protection Violation Status (WPVS) flag in the Write Protection Status register (I2SMCC_WPSR) is set and the field Write Protection Violation Source (WPVSRC) indicates the register in which the write access has been attempted. An interrupt can be raised if the Write Error (WERR) interrupt is set in I2SMCC_IMRB.

The WPVS flag is automatically reset by reading I2SMCC_WPSR.

The following register can be write-protected with the I2SMCC_WPMR.WPCFEN bit:

- Inter-IC Sound Multi Channel Controller Mode Register A
- Inter-IC Sound Multi Channel Controller Mode Register B

The following registers can be write-protected with the I2SMCC_WPMR.WPITEN bit:

- Inter-IC Sound Multi Channel Controller Interrupt Enable Register A
- Inter-IC Sound Multi Channel Controller Interrupt Disable Register A
- Inter-IC Sound Multi Channel Controller Interrupt Enable Register B
- Inter-IC Sound Multi Channel Controller Interrupt Disable Register B

The following register can be write-protected with the I2SMCC_WPMR.WPCTEN bit:

- Inter-IC Sound Multi Channel Controller Control Register

45.6.15 Functional Safety (Protection, Monitors and Reports)

45.6.15.1 Protections

The configuration, interrupt and control registers can be protected against unintentional write accesses resulting from an erroneous software, bad DMA configuration or any abnormal single event upset that would create a spurious access on the bus. See Register Write Protection for a detailed description.

45.6.15.2 Monitors and Reports

When register write protection is enabled, any incorrect access is reported in I2SMCC_WPSR.WPVS and in I2SMCC_ISRB.WERR. It is possible to trigger an interrupt by writing a ‘1’ in I2SMCC_IERB.WERR.

I2SMCC embeds an on-the-fly monitoring of the WS and CK output pads to speed-up detection and report of any error while transmitting a data. The monitor cannot be disabled for safety reason and only reports an error in the user interface (i.e. there is no action on transmission path).

The I2SMCC internal outputs are passed through IO multiplexing logic that may be unintentionally badly configured and leads to absence or bad transmission. Other causes of stuck-at are detected (external cause such as short-circuits or internal cause such as pad buffer transistor failure). As an example, a badly re-assigned I2SMCC_WS/CK IO pin (software error) is detected as soon as the I2SMCC starts transmitting a data because it is unlikely for another peripheral sharing the same IO pin to drive the same waveform as the I2SMCC on I2SMCC_WS/CK output.

The monitor is enabled when the I2SMCC is configured in Host mode (I2SMCC_MRA.MODE=1).

An error is reported in I2SMCC_WPSR.PADERR and in I2SMCC_ISR.SECE when there is evidence that the output values on I2SMCC_WS or I2SMCC_CK differ from the internal values generated by the I2SMCC.

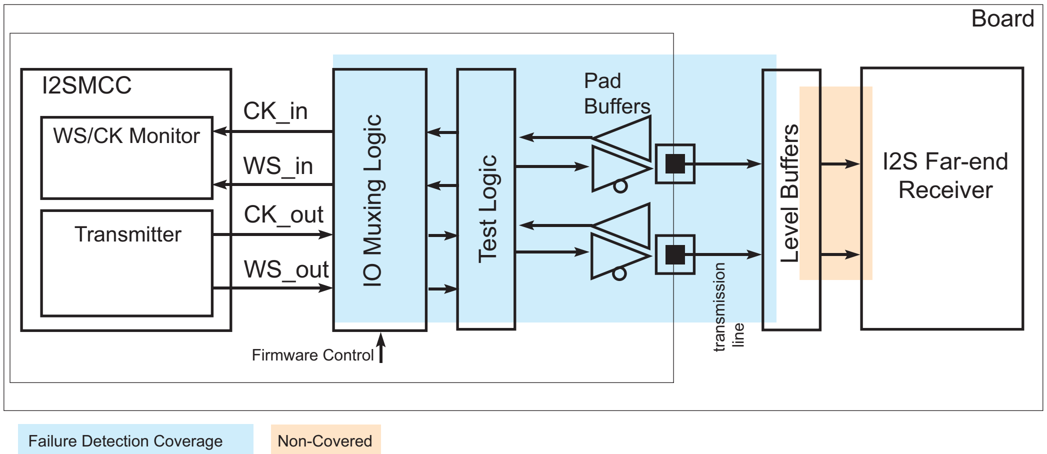
When an I2S format is configured (I2SMCC_MRA.FORMAT < 2), the I2SMCC_WS output pad value is oversampled by 2 and, as soon as 2 consecutive samples differ from the internal value generated by the I2SMCC, an error is reported. The rising edges of the I2SMCC_CK output are counted during a reference period equal to an audio sample period and at the end of each counting period, an error is reported if the counter is below seven at the end of the reference period (the minimum data length of an audio sample being eight bits).

When a TDM format is configured (I2SMCC_MRA.FORMAT > 1), the I2SMCC_WS output is monitored in a manner that differs from I2S formats because the waveform of WS can be configured with a minimum high duration pulse of 1 bit time. An error is reported if no falling edge is detected (thus the monitor checks that the output level is not stuck at 1 or 0). The I2SMCC_CK check is performed in the same way as in I2S format.

The detection method minimizes the likelihood to report a false positive that could result for example from a single upset event.

The monitor covers any failure that would be located in the I2SMCC IO multiplexing downstream circuitry, test logic, output pad buffer and external transmission line from the output pad to any buffering circuitry (if discrete components are placed between the transmitter and far-end receiver).

Figure 45-8. Failure Detection Coverage for the I2SMCC Monitor



When an error is reported, it is possible to trigger an interrupt by writing a ‘1’ in I2SMCC_IER.SECE.

45.7 Register Summary

Offset	Name	Bit Pos.	7	6	5	4	3	2	1	0
0x00	I2SMCC_CR	31:24								
		23:16								
		15:8								
		7:0	SWRST		TXDIS	TXEN	CKDIS	CKEN	RXDIS	RXEN
0x04	I2SMCC_MRA	31:24	IWS	IMCKMODE	ISCKDIV[5:0]					
		23:16	TDMFS[1:0]		IMCKDIV[5:0]

45.7.1 I2SMCC Control Register

Name: I2SMCC_CR
Offset: 0x00
Reset: –
Property: Write-only

This register can only be written if the WPCTEN bit is cleared in the Inter-IC Sound Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
	SWRST		TXDIS	TXEN	CKDIS	CKEN	RXDIS	RXEN
Access	W		W	W	W	W	W	W
Reset	–		–	–	–	–	–	–

Bit 7 – SWRST Software Reset

Value	Description
0	No effect.
1	Resets all the registers in the I2SMCC. The I2SMCC is disabled after the reset.

Bit 5 – TXDIS Transmitter Disable

Value	Description
0	No effect.
1	Disables the I2SMCC transmitter. Bit I2SMCC_SR.TXEN is cleared when the Transmitter is stopped.

Bit 4 – TXEN Transmitter Enable

Value	Description
0	No effect.
1	Enables the I2SMCC transmitter, if TXDIS is not ‘1’. Bit I2SMCC_SR.TXEN is set when the Transmitter is started.

Bit 3 – CKDIS Clocks Disable

Value	Description
0	No effect.
1	Disables the I2SMCC clock generation.

Bit 2 – CKEN Clocks Enable

Value	Description
0	No effect.
1	Enables the I2SMCC clock generation, if CKDIS is not ‘1’.

Bit 1 – RXDIS Receiver Disable

Value	Description
0	No effect.
1	Disables the I2SMCC receiver. Bit I2SMCC_SR.RXEN is cleared when the receiver is stopped.

Bit 0 – RXEN Receiver Enable

Value	Description
0	No effect.
1	Enables the I2SMCC receiver, if RXDIS is not ‘1’. Bit I2SMCC_SR.RXEN is set when the receiver is activated.

45.7.2 I2SMCC Mode Register A

Name: I2SMCC_MRA
Offset: 0x04
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPCFEN bit is cleared in Inter-IC Sound Write Protection Mode Register.

The I2SMCC_MRA must only be written when the I2SMCC is stopped in order to avoid unexpected behavior on the I2SMCC_WS, I2SMCC_CK and I2SMCC_DOUTx outputs. The proper sequence is to write to I2SMCC_MRA, then write to I2SMCC_CR to enable the I2SMCC or to disable the I2SMCC before writing a new value to I2SMCC_MRA.

Bit	31	30	29	28	27	26	25	24
	IWS	IMCKMODE	ISCKDIV[5:0]					
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	TDMFS[1:0]		IMCKDIV[5:0]					
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	NBCHAN[2:0]			SRCCLK	TXSAME	TXMONO	RXLOOP	RXMONO
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	FORMAT[1:0]		WIRECFG[1:0]		DATALENGTH[2:0]			MODE
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit 31 – IWS I2SMCC_WS Slot Length
See tables Slot Length (I^{2}S format) and Slot Length (Left-Justified format).

Value	Description
0	I2SMCC_WS slot is 32 bits long for DATALENGTH = 18/20/24 bits.
1	I2SMCC_WS slot is 24 bits long for DATALENGTH = 18/20/24 bits.

Bit 30 – IMCKMODE Host Clock Mode

Value	Description
0	No host clock generated.
1	Host clock generated.

Bits 29:24 – ISCKDIV[5:0] Selected Clock to I2SMCC Serial Clock Ratio
I2SMCC_CK Serial clock output frequency is Selected Clock divided by (2 * ISCKDIV). If ISCKDIV is 0, the I2SMCC_CK Serial clock output frequency is equal to the Selected Clock frequency.

Bits 23:22 – TDMFS[1:0] TDM Frame Synchronization

Value	Name	Description
0	SLOT	I2SMCC_WS pulse is high for one time slot at beginning of frame.
1	HALF	I2SMCC_WS pulse is high for half the time slots at beginning of frame.
2	BIT	I2SMCC_WS pulse is high for one bit period at beginning of frame, i.e., one ISCK period.

Bits 21:16 – IMCKDIV[5:0] Selected Clock to I2SMCC Host Clock Ratio
I2SMCC_MCK Host clock output frequency is Selected Clock divided by (2 * IMCKDIV). If IMCKDIV is 0, the I2SMCC_MCK Host clock output frequency is equal to the Selected Clock frequency.

Bits 15:13 – NBCHAN[2:0] Number of TDM Channels-1
Must be written with the number of TDM channels minus one.

Bit 12 – SRCCLK Source Clock Selection

Value	Description
0	The Peripheral clock is selected as source clock for I2SMCC_MCK/WS/CK pins.
1	The PMC.GCLKx clock is selected as source clock (I2SMCC_MCK/WS/CK rate can be independent of system bus clock).

Bit 11 – TXSAME Transmit Data when Underrun

Value	Description
0	‘0’ is transmitted when underrun.
1	Previous sample transmitted when underrun.

Bit 10 – TXMONO Transmit Mono

Value	Description
0	Stereo
1	Mono, with left audio samples duplicated to right audio channel by the I2SMCC.

Bit 9 – RXLOOP Loop-back Test Mode

Value	Description
0	Normal mode
1	I2SMCC_DOUT outputs of I2SMCC are internally connected to I2SMCC_DIN inputs.

Bit 8 – RXMONO Receive Mono

Value	Description
0	Stereo
1	Mono, with left audio samples duplicated to right audio channel by the I2SMCC.

Bits 7:6 – FORMAT[1:0] Data Format

Value	Name	Description
0	I2S	I^2S format, stereo with I2SMCC_WS low for left channel, and MSB of sample starting one I2SMCC_CK period after I2SMCC_WS edge.
1	LJ	Left-justified format, stereo with I2SMCC_WS high for left channel, and MSB of sample starting on I2SMCC_WS edge.
2	TDM	TDM format, with (NBCHAN + 1) channels, I2SMCC_WS high at beginning of first channel, and MSB of sample starting one I2SMCC_CK period after I2SMCC_WS edge.
3	TDMLJ	TDM format, left-justified, with (NBCHAN + 1) channels, I2SMCC_WS high at beginning of first channel, and MSB of sample starting on I2SMCC_WS edge.

Bits 5:4 – WIRECFG[1:0] Wire Configuration

Value	Name	Description
0	I2S_1_TDM_0	In I^2S and LJ formats, I2SMCC_DIN0 and I2SMCC_DOUT0 are used to transmit and receive I^2S frames. In TDM and TDMLJ formats, I2SMCC_DIN0 and I2SMCC_DOUT0 are used to transmit and receive TDM frames.
1	I2S_2_TDM_1	In I^2S and LJ formats, I2SMCC_DIN1..0 and I2SMCC_DOUT1..0 are used to transmit and receive 2 I^2S frames. In TDM and TDMLJ formats, I2SMCC_DIN1 and I2SMCC_DOUT1 are used to transmit and receive TDM frames.
2	I2S_4_TDM_2	In I^2S and LJ formats, I2SMCC_DIN3..0 and I2SMCC_DOUT3..0 are used to transmit and receive 4 I^2S frames. In TDM and TDMLJ formats, I2SMCC_DIN2 and I2SMCC_DOUT2 are used to transmit and receive TDM frames.

Value	Name	Description
3	TDM_3	In I^2S and LJ formats, reserved for future use, do not use. In TDM and TDMLJ formats, I2SMCC_DIN3 and I2SMCC_DOUT3 are used to transmit and receive TDM frames.

Bits 3:1 – DATALENGTH[2:0] Data Word Length

Value	Name	Description
0	32_BITS	Data length is set to 32 bits.
1	24_BITS	Data length is set to 24 bits.
2	20_BITS	Data length is set to 20 bits.
3	18_BITS	Data length is set to 18 bits.
4	16_BITS	Data length is set to 16 bits.
5	16_BITS_COMPACT	Data length is set to 16-bit compact stereo. Left sample in bits [15:0] and right sample in bits [31:16] of same word.
6	8_BITS	Data length is set to 8 bits.
7	8_BITS_COMPACT	Data length is set to 8-bit compact stereo. Left sample in bits [7:0] and right sample in bits [15:8] of the same word.

Bit 0 – MODE I2SMCC Mode

Value	Name	Description
0	SLAVE	Client mode. I2SMCC_CK and I2SMCC_WS pin inputs used as bit clock and word select/ frame synchronization.
1	MASTER	Host mode. Bit clock and word select/frame synchronization generated by I2SMCC from Peripheral Clock or GCLK if I2SMCC_MCK/WS/CK rates must be independent of system bus clock (See I2SMCC_MR.SRCCLK) and output to I2SMCC_CK and I2SMCC_WS pins. MCK is output as host clock on I2SMCC_MCK if I2SMCC_MRA.IMCKMODE is set.

45.7.3 I2SMCC Mode Register B

Name: I2SMCC_MRB
Offset: 0x08
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPCFEN bit is cleared in the Inter-IC Sound Write Protection Mode Register.

The I2SMCC_MRB must only be written when the I2SMCC is stopped in order to avoid unexpected behavior on the I2SMCC_WS, I2SMCC_CK and I2SMCC_DOUT outputs. The proper sequence is to write to I2SMCC_MRB, then write to I2SMCC_CR to enable the I2SMCC or to disable the I2SMCC before writing a new value to I2SMCC_MRB.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
							DMACHUNK[1:0]	
Access							R/W	R/W
Reset							0	0

Bit	7	6	5	4	3	2	1	0
				FIFOEN				CRAMODE
Access				R/W				R/W
Reset				0				0

Bits 9:8 – DMACHUNK[1:0] DMA Chunk Size

Value	Name	Description
0	1_WORD	Each DMA transfer contains 1 word.
1	2_WORDS	Each DMA transfer contains 2 words.
2	4_WORDS	Each DMA transfer contains 4 words.
3	8_WORDS	Each DMA transfer contains 8 words.

Bit 4 – FIFOEN FIFO Enable

Value	Description
0	The Receive and Transmit FIFOs are disabled.
1	The Receive and Transmit FIFOs are enabled. Transmit data can only be written through I2SMCC_THR. Receive data can only be read through I2SMCC_RHR.

Bit 0 – CRAMODE Common Register Access Mode

Value	Name	Description
0	LEFT_FIRST	All enabled I^2S left channels are filled first, then I^2S right channels.
1	REGULAR	An enabled I^2S left channel is filled, then the corresponding right channel, until all channels are filled.

45.7.4 I2SMCC Status Register

Name: I2SMCC_SR
Offset: 0x0C
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								
Bit	23	22	21	20	19	18	17	16
Access								
Reset								
Bit	15	14	13	12	11	10	9	8
Access								
Reset								
Bit	7	6	5	4	3	2	1	0
				TXEN				RXEN
Access				R				R
Reset				0				0

Bit 4 – TXEN Transmitter Enabled
TXEN=1 if the selected clock (internal bit clock, see the figure I2SMCC Clock Generation) is active and WS is active.

Value	Description
0	Cleared when the transmitter is disabled, following a I2SMCC_CR.TXDIS or I2SMCC_CR.SWRST request.
1	Set when the transmitter is enabled, following a I2SMCC_CR.TXEN request.

Bit 0 – RXEN Receiver Enabled
RXEN=1 if the selected clock (internal bit clock, see the figure I2SMCC Clock Generation) is active and WS is active.

Value	Description
0	Cleared when the receiver is disabled, following an RXDIS or SWRST request in I2SMCC_CR.
1	Set when the receiver is enabled, following an RXEN request in I2SMCC_CR.

45.7.5 I2SMCC Interrupt Enable Register A

Name: I2SMCC_IERA
Offset: 0x10
Reset: –
Property: Write-only

This register can only be written if the WPITEN bit is cleared in the Inter-IC Sound Write Protection Mode Register.

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Enables the corresponding interrupt.

Bit	31	30	29	28	27	26	25	24
	RXROVF3	RXLOVF3	RXROVF2	RXLOVF2	RXROVF1	RXLOVF1	RXROVF0	RXLOVF0
Access	W	W	W	W	W	W	W	W
Reset	–	–	–	–	–	–	–	–

Bit	23	22	21	20	19	18	17	16
	RXRRDY3	RXLRDY3	RXRRDY2	RXLRDY2	RXRRDY1	RXLRDY1	RXRRDY0	RXLRDY0

	TXRRDY3	TXLRDY3	TXRRDY2	TXLRDY2	TXRRDY1	TXLRDY1	TXRRDY0	TXLRDY0
Access	W	W	W	W	W	W	W	W
Reset	–	–	–	–	–	–	–	–

Bits 25, 27, 29, 31 – RXROVFx I^{2}S Receive Right x or TDM Channel [2x]+1 Overrun Interrupt Enable

Bits 24, 26, 28, 30 – RXLOVFx I^{2}S Receive Left x or TDM Channel 2x Overrun Interrupt Enable

Bits 17, 19, 21, 23 – RXRRDYx I^{2}S Receive Right x or TDM Channel [2x]+1 Ready Interrupt Enable

Bits 16, 18, 20, 22 – RXLRDYx I^{2}S Receive Left x or TDM Channel 2x Ready Interrupt Enable

Bits 9, 11, 13, 15 – TXRUNFx I^{2}S Transmit Right x or TDM Channel [2x]+1 Underrun Interrupt Enable

Bits 8, 10, 12, 14 – TXLUNFx I^{2}S Transmit Left x or TDM Channel 2x Underrun Interrupt Enable

Bits 1, 3, 5, 7 – TXRRDYx I^{2}S Transmit Right x or TDM Channel [2x]+1 Ready Interrupt Enable

Bits 0, 2, 4, 6 – TXLRDYx I^{2}S Transmit Left x or TDM Channel 2x Ready Interrupt Enable

45.7.6 I2SMCC Interrupt Disable Register A

Name: I2SMCC_IDRA
Offset: 0x14
Reset: –
Property: Write-only

This register can only be written if the WPITEN bit is cleared in the Inter-IC Sound Write Protection Mode Register.

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Disables the corresponding interrupt.

Bit	31	30	29	28	27	26	25	24
	RXROVF3	RXLOVF3	RXROVF2	RXLOVF2	RXROVF1	RXLOVF1	RXROVF0	RXLOVF0

Bits 25, 27, 29, 31 – RXROVFx I^2S Receive Right x or TDM Channel [2x]+1 Overrun Flag (Cleared on read)

Value	Description
0	Cleared when I2SMCC_ISRA is read.
1	Set when an overrun error occurs in either I2SMCC_RHRxR or I2SMCC_RHR.

Bits 24, 26, 28, 30 – RXLOVFx I^2S Receive Left x or TDM Channel 2x Overrun Flag (Cleared on read)

Value	Description
0	Cleared when I2SMCC_ISRA is read.
1	Set when an overrun error occurs in either I2SMCC_RHLxR or I2SMCC_RHR.

Bits 17, 19, 21, 23 – RXRRDYx I^2S Receive Right x or TDM Channel [2x]+1 Ready Flag (Cleared by reading I2SMCC_RHR/RHLxR)

Value	Description
0	Cleared when a predefined number of read accesses are performed in I2SMCC_RHRxR or I2SMCC_RHR. The predefined number depends on the configuration of I2SMCC_MRA.WIRECFG / FORMAT and varies from 1 to 8.
1	Set when received data is available in either I2SMCC_RHRxR or I2SMCC_RHR.

Bits 16, 18, 20, 22 – RXLRDYx I^2S Receive Left x or TDM Channel 2x Ready Flag (Cleared by reading I2SMCC_RHR/RHLxR)

Value	Description
0	Cleared when a predefined number of write accesses is performed in either I2SMCC_RHLxR or I2SMCC_RHR. The predefined number depends on the configuration of I2SMCC_MRA.WIRECFG/ FORMAT and varies from 1 to 7.
1	Set when received data is available in either I2SMCC_RHLxR or I2SMCC_RHR.

Bits 9, 11, 13, 15 – TXRUNFx I^2S Transmit Right x or TDM Channel [2x]+1 Underrun Flag (Cleared on read)

Value	Description
0	Cleared when the I2SMCC_ISRA is read.
1	Set when an underrun error occurs in either I2SMCC_THR or I2SMCC_THRxR.

Bits 8, 10, 12, 14 – TXLUNFx I^2S Transmit Left x or TDM Channel 2x Underrun (Cleared on read)

Value	Description
0	Cleared when I2SMCC_ISRA is read.
1	Set when an underrun error occurs in either I2SMCC_THR or I2SMCC_THLxR.

Bits 1, 3, 5, 7 – TXRRDYx I^2S Transmit Right x or TDM Channel [2x]+1 Ready Flag (Cleared by writing I2SMCC_THR/THRxR)

Value	Description
0	Cleared when a predefined number of write accesses is performed in either I2SMCC_THRxR or I2SMCC_THR. The predefined number depends on the configuration of I2SMCC_MRA.WIRECFG/FORMAT and varies from 1 to 7.
1	Set when I2SMCC_THR or I2SMCC_THRxR is empty.

Bits 0, 2, 4, 6 – TXLRDYx I^2S Transmit Left x or TDM Channel 2x Ready Flag (Cleared by writing I2SMCC_THR/THLxR)

Value	Description
0	Cleared when a predefined number of write accesses is performed in either I2SMCC_THLxR or I2SMCC_THR. The predefined number depends on the configuration of I2SMCC_MRA.WIRECFG/FORMAT and varies from 1 to 7.
1	Set when I2SMCC_THR or I2SMCC_THLxR is empty.

45.7.9 I2SMCC Interrupt Enable Register B

Name: I2SMCC_IERB
Offset: 0x20
Reset: –
Property: Write-only

This register can only be written if the WPITEN bit is cleared in the Inter-IC Sound Write Protection Mode Register.

The following configuration values are valid for the listed bits of this register:

0: No effect.

1: Enables the corresponding interrupt.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16

Bit 13 – RXFFFUL RX FIFO Full Interrupt Enable

Bit 12 – RXFFRDY RX FIFO Ready Interrupt Enable

Bit 9 – TXFFEMP TX FIFO Empty Interrupt Enable

Bit 8 – TXFFRDY TX FIFO Ready Interrupt Enable

Bit 0 – WERR Write Error Interrupt Enable

45.7.10 I2SMCC Interrupt Disable Register B

Name: I2SMCC_IDRB
Offset: 0x24
Reset: –
Property: Write-only

This register can only be written if the WPITEN bit is cleared in the Inter-IC Sound Write Protection Mode Register.

The following configuration values are valid for the listed bits of this register:

0: No effect.

1: Disables the corresponding interrupt.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16

Bit 12 – RXFFRDY RX FIFO Ready Interrupt Mask

Bit 9 – TXFFEMP TX FIFO Empty Interrupt Mask

Bit 8 – TXFFRDY TX FIFO Ready Interrupt Mask

Bit 0 – WERR Write Error Interrupt Mask

45.7.12 I2SMCC Interrupt Status Register B

Name: I2SMCC_ISRB
Offset: 0x2C
Reset: 0x00000000
Property: Read-only

When I2SMCC_MRB.FIFOEN = 0, TXFFRDY, TXFFEMP, RXFFRDY and RXFFFUL are not relevant. Refer to I2SMCC_ISRA.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
			RXFFFUL	RXFFRDY			TXFFEMP	TXFFRDY
Access			R	R			R	R
Reset			0	0			0	0

Bit	7	6	5	4	3	2	1	0
								WERR
Access								R
Reset								0

Bit 13 – RXFFFUL RX FIFO Full Flag (Cleared on read)

Value	Description
0	Cleared when I2SMCC_ISRB is read.
1	Set when RX FIFO is full and I2SMCC_MRB.FIFOEN = 1.

Bit 12 – RXFFRDY RX FIFO Ready Flag (Cleared on read)

Value	Description
0	Cleared when I2SMCC_ISRB is read.
1	Set when RX FIFO is ready to be read and I2SMCC_MRB.FIFOEN = 1.

Bit 9 – TXFFEMP TX FIFO Empty Flag (Cleared on read)

Value	Description
0	Cleared when I2SMCC_ISRB is read.
1	Set when TX FIFO is empty and I2SMCC_MRB.FIFOEN = 1.

Bit 8 – TXFFRDY TX FIFO Ready Flag (Cleared on read)

Value	Description
0	Cleared when I2SMCC_ISRB is read.
1	Set when TX FIFO is ready to be written and I2SMCC_MRB.FIFOEN = 1.

Bit 0 – WERR Write Error Flag (Cleared on read)

Value	Description
0	Cleared when the I2SMCC_ISRB is read.
1	Set when a write occurs in a protected register.

45.7.13 I2SMCC Receiver Holding Register

Name: I2SMCC_RHR
Offset: 0x30
Reset: 0x00000000
Property: Read-only

Bits 31:8 – WPKEY[23:0] Write Protection Key

Value	Name	Description
0x493253	PASSWD	Writing any other value in this field aborts the write operation. Always reads as 0.

Bit 2 – WPCTEN Write Protection Control Enable

Value	Description
0	Disables the write protection of the control if WPKEY matches to 0x493253 (I2S in ASCII).
1	Enables the write protection of the control if WPKEY matches to 0x493253 (I2S in ASCII).

Bit 1 – WPITEN Write Protection Interrupt Enable

Value	Description
0	Disables the write protection of the interruption if WPKEY matches to 0x493253 (I2S in ASCII).
1	Enables the write protection of the interruption if WPKEY matches to 0x493253 (I2S in ASCII).

Bit 0 – WPCFEN Write Protection Configuration Enable

Value	Description
0	Disables the write protection of the configuration if WPKEY matches to 0x493253 (I2S in ASCII).
1	Enables the write protection of the configuration if WPKEY matches to 0x493253 (I2S in ASCII).

45.7.20 I2SMCC Write Protection Status Register

Bits 31:8 – WPVSRC[23:0] Write Protection Violation Source
When WPVS = 1, WPVSRC indicates the register address offset at which a write access has been attempted.

Bit 0 – WPVS Write Protection Violation Status

Value	Description
0	No write protection violation has occurred since the last read of the I2SMCC_WPSR.
1	A write protection violation has occurred since the last read of the I2SMCC_WPSR. If this violation is an unauthorized attempt to write a protected register, the associated violation is reported into field WPVSRC.

46. Synchronous Serial Controller (SSC)

46.1 Description

The Synchronous Serial Controller (SSC) provides a synchronous communication link with external devices. It supports many serial synchronous communication protocols generally used in audio and telecom applications such as I2S, Short Frame Sync, Long Frame Sync, etc.

The SSC contains an independent receiver and transmitter and a common clock divider. The receiver and the transmitter each interface with three signals: the TD/RD signal for data, the TK/RK signal for the clock and the TF/RF signal for the Frame Sync. The transfers can be programmed to start automatically or on different events detected on the Frame Sync signal.

The SSC high-level of programmability and its use of DMA enable a continuous high bit rate data transfer without processor intervention.

Featuring connection to the DMA, the SSC enables interfacing with low processor overhead to:

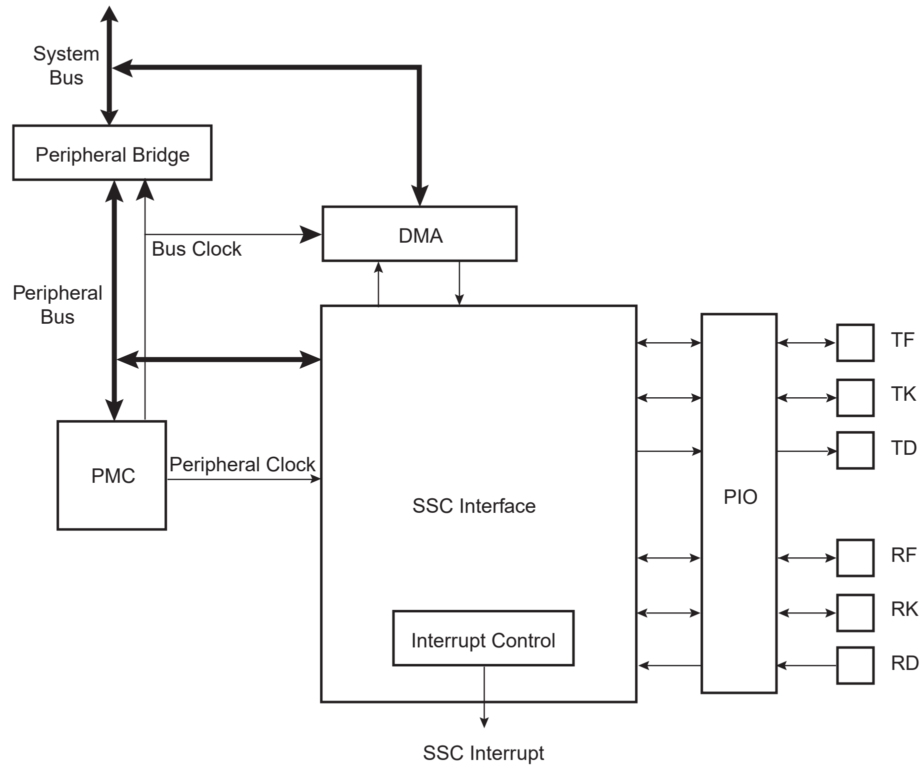
- Codecs in Host or Client mode
- DAC through dedicated serial interface, particularly I2S
- Magnetic card reader

46.2 Embedded Characteristics

- Provides Serial Synchronous Communication Links Used in Audio and Telecom Applications
- Contains an Independent Receiver and Transmitter and a Common Clock Divider
- Interfaced with the DMA Controller (DMAC) to Reduce Processor Overhead
- Offers a Configurable Frame Sync and Data Length
- Receiver and Transmitter Can be Programmed to Start Automatically or on Detection of Different Events on the Frame Sync Signal
- Receiver and Transmitter Include a Data Signal, a Clock Signal and a Frame Sync Signal
- 8 data transmit FIFO
- 8 data transmit FIFO

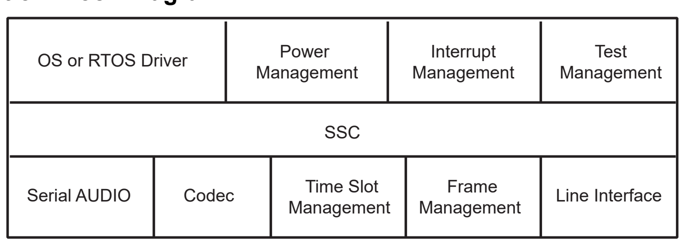
46.3 Block Diagram

Figure 46-1. SSC Block Diagram



46.4 Application Block Diagram

Figure 46-2. SSC Application Block Diagram



46.5 SSC Application Examples

The SSC can support several serial communication modes used in audio or high speed serial links. Some standard applications are shown in the following figures. All serial link applications supported by the SSC are not listed here.

Figure 46-3. Audio Application Block Diagram

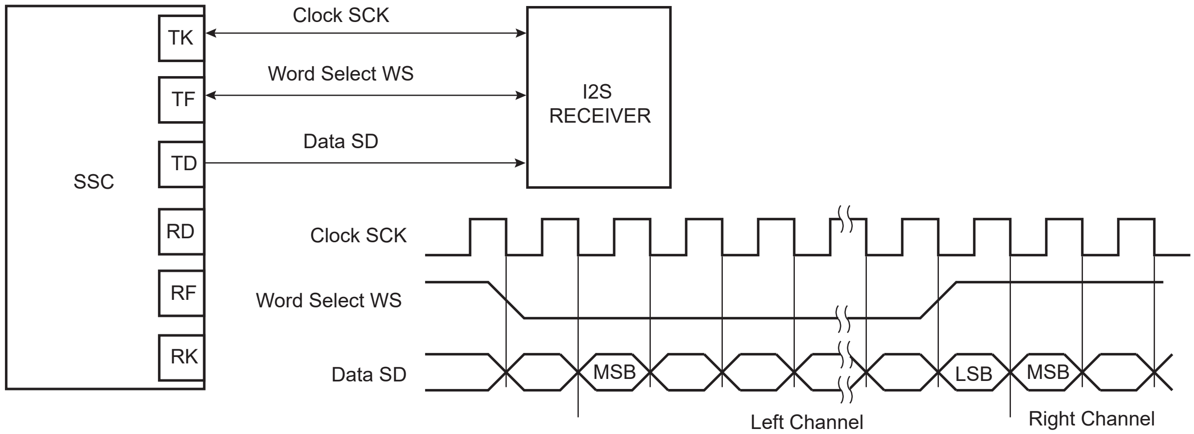


Figure 46-4. Codec Application Block Diagram

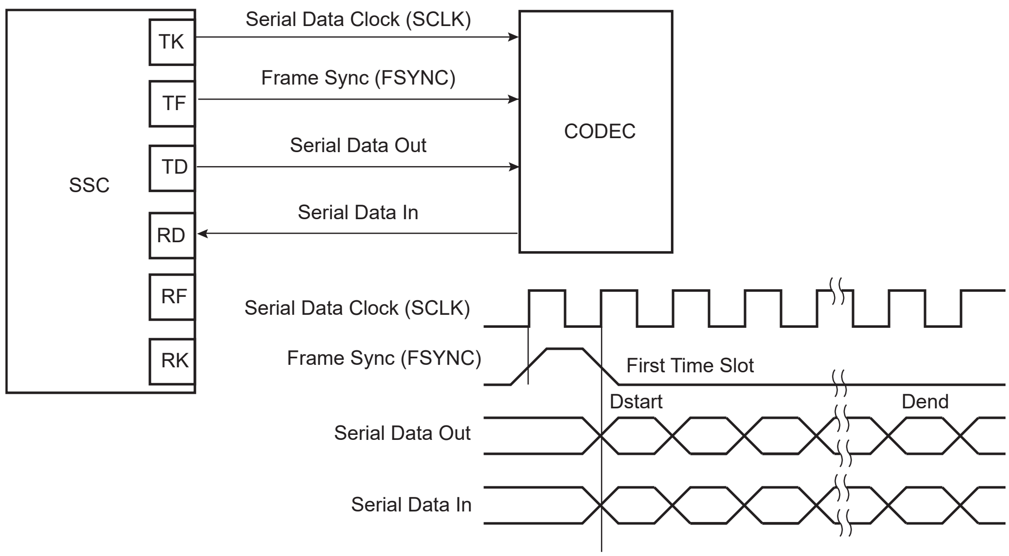

Figure 46-5. Time Slot Application Block Diagram

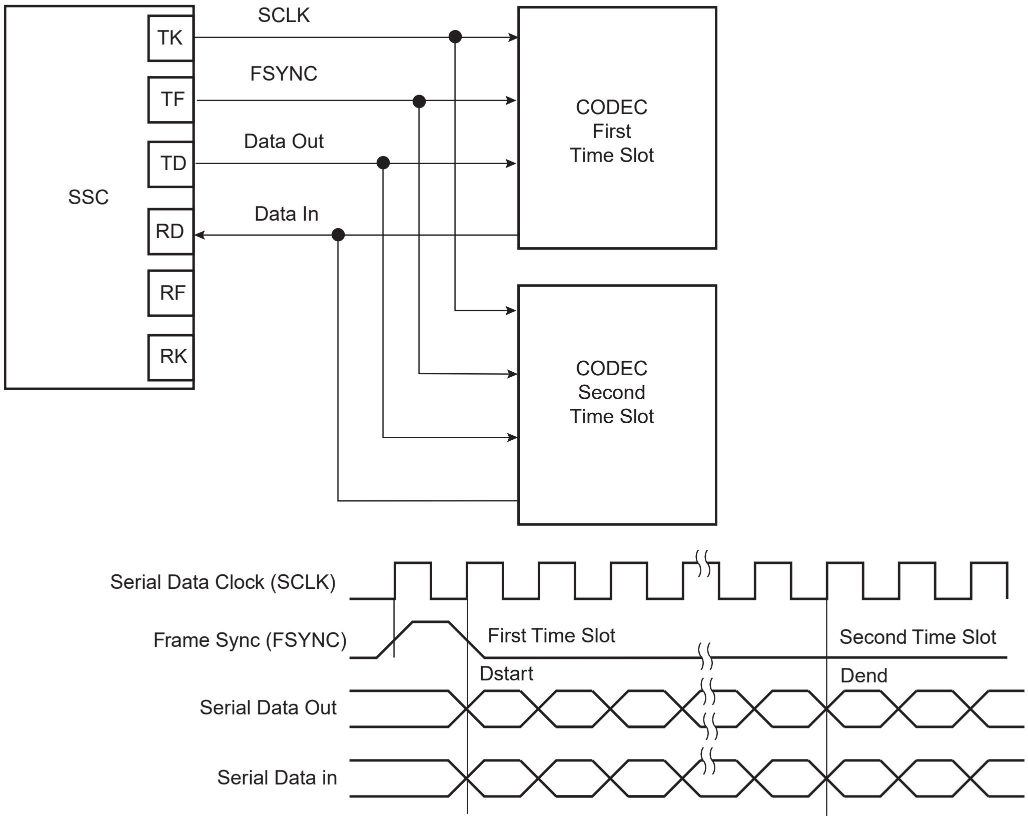


46.6 Pin Name List

Table 46-1. I/O Lines Description

Pin Name	Pin Description	Type
RF	Receive Frame Synchronization	Input/Output
RK	Receive Clock	Input/Output
RD	Receive Data	Input
TF	Transmit Frame Synchronization	Input/Output
TK	Transmit Clock	Input/Output
TD	Transmit Data	Output

46.7 Product Dependencies

46.7.1 I/O Lines

The pins used for interfacing the compliant external devices may be multiplexed with PIO lines.

Before using the SSC receiver, the PIO controller must be configured to dedicate the SSC receiver I/O lines to the SSC Peripheral mode.

Before using the SSC transmitter, the PIO controller must be configured to dedicate the SSC transmitter I/O lines to the SSC Peripheral mode.

46.7.2 Power Management

The SSC is not continuously clocked. The SSC interface may be clocked through the Power Management Controller (PMC), therefore the programmer must first configure the PMC to enable the SSC clock.

46.7.3 Interrupt

The SSC interface has an interrupt line connected to the interrupt controller. Handling interrupts requires programming the interrupt controller before configuring the SSC.

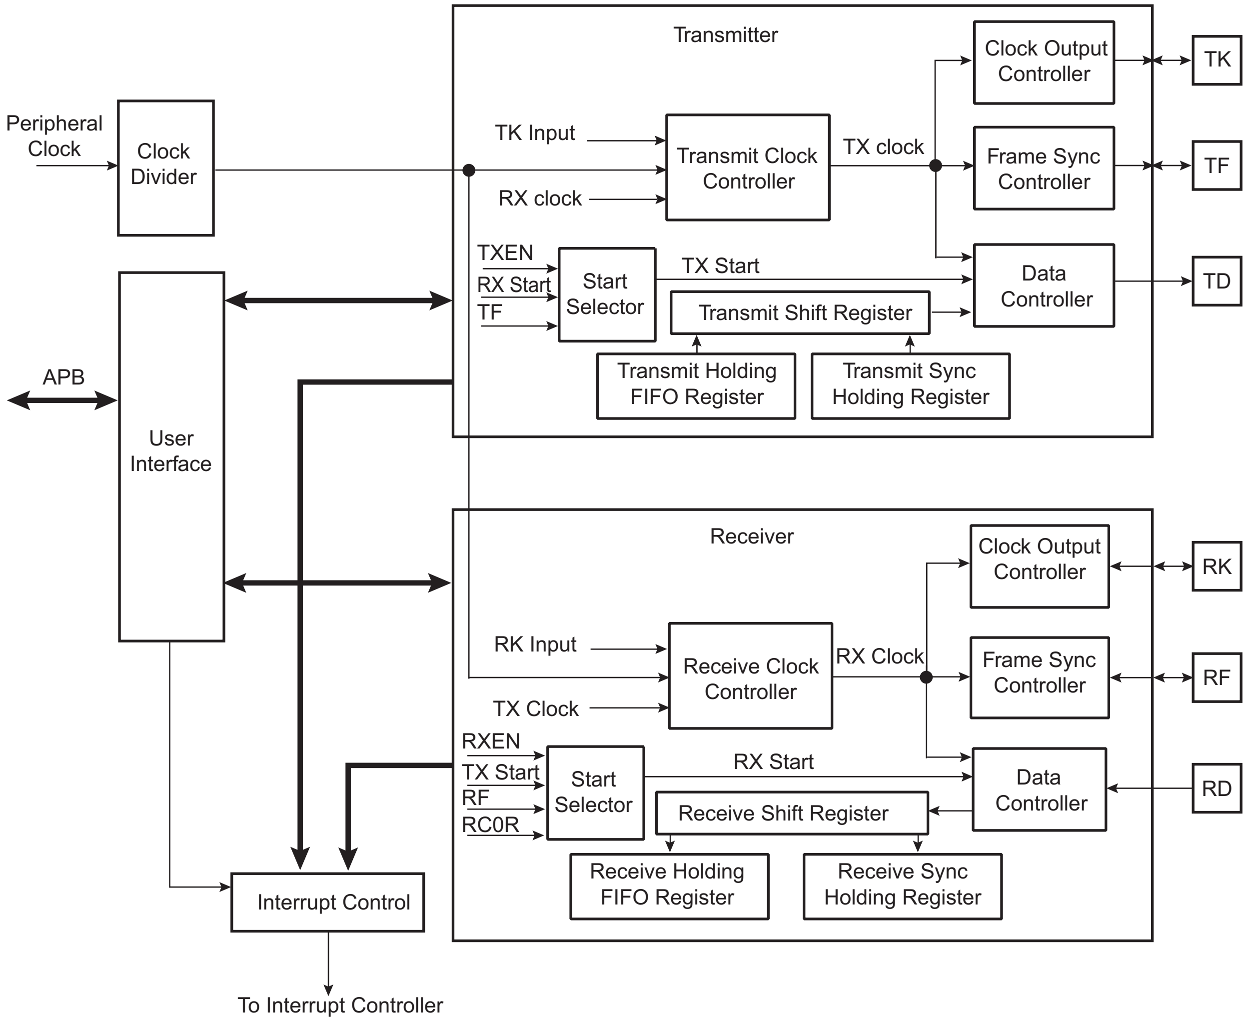
All SSC interrupts can be enabled/disabled configuring the SSC Interrupt Mask Register. Each pending and unmasked SSC interrupt asserts the SSC interrupt line. The SSC interrupt service routine can get the interrupt origin by reading the SSC Interrupt Status Register.

46.8 Functional Description

This section contains the functional description of the following: SSC Functional Block, Clock Management, Data Format, Start, Transmit, Receive and Frame Synchronization.

The receiver and transmitter operate separately. However, they can work synchronously by programming the receiver to use the transmit clock and/or to start a data transfer when transmission starts. Alternatively, this can be done by programming the transmitter to use the receive clock and/or to start a data transfer when reception starts. The transmitter and the receiver can be programmed to operate with the clock signals provided on either the TK or RK pins. This allows the SSC to support many Client mode data transfers. The maximum clock speed allowed on the TK and RK pins is the peripheral clock divided by 2.

Figure 46-6. SSC Functional Block Diagram



46.8.1 Clock Management

The transmit clock can be generated by:

- an external clock received on the TK I/O pad
- the receive clock
- the internal clock divider

The receive clock can be generated by:

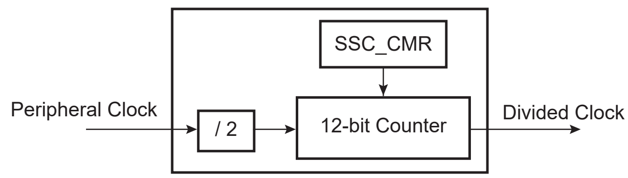
- an external clock received on the RK I/O pad
- the transmit clock
- the internal clock divider

Furthermore, the transmitter block can generate an external clock on the TK I/O pad, and the receive block can generate an external clock on the RK I/O pad.

This allows the SSC to support many Host and Client mode data transfers.

46.8.1.1 Clock Divider

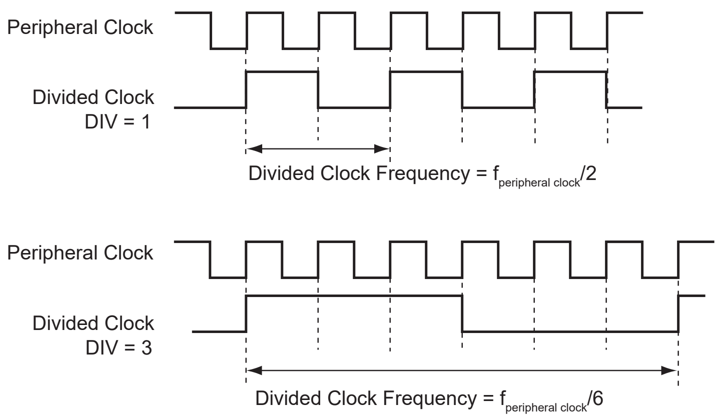
Figure 46-7. Divided Clock Block Diagram



The peripheral clock divider is determined by the 12-bit field DIV counter and comparator (so its maximal value is 4095) in the Clock Mode Register (SSC_CMR), allowing a peripheral clock division by up to 8190. The Divided Clock is provided to both the receiver and the transmitter. When this field is programmed to 0, the Clock Divider is not used and remains inactive.

When DIV is set to a value equal to or greater than 1, the Divided Clock has a frequency of peripheral clock divided by 2 times DIV. Each level of the Divided Clock has a duration of the peripheral clock multiplied by DIV. This ensures a 50% duty cycle for the Divided Clock regardless of whether the DIV value is even or odd.

Figure 46-8. Divided Clock Generation

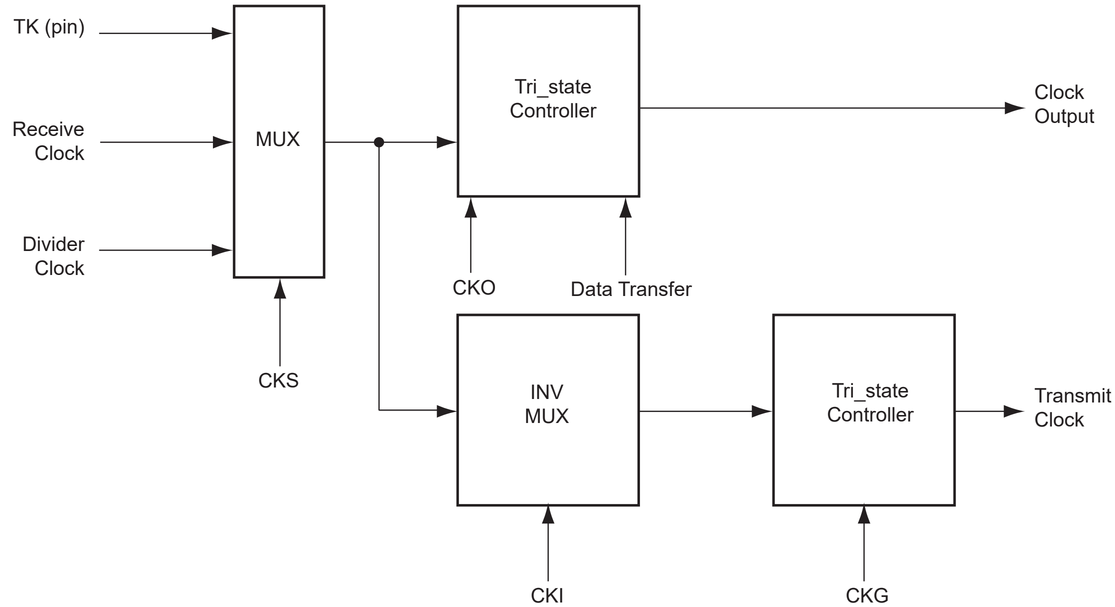


46.8.1.2 Transmit Clock Management

The transmit clock is generated from the receive clock or the divider clock or an external clock scanned on the TK I/O pad. The transmit clock is selected by the CKS field in the Transmit Clock Mode Register (SSC_TCMR). Transmit Clock can be inverted independently by the CKI bits in the SSC_TCMR.

The transmitter can also drive the TK I/O pad continuously or be limited to the current data transfer. The clock output is configured by the SSC_TCMR. The Transmit Clock Inversion (CKI) bits have no effect on the clock outputs. Programming the SSC_TCMR to select TK pin (CKS field) and at the same time Continuous Transmit Clock (CKO field) can lead to unpredictable results.

Figure 46-9. Transmit Clock Management

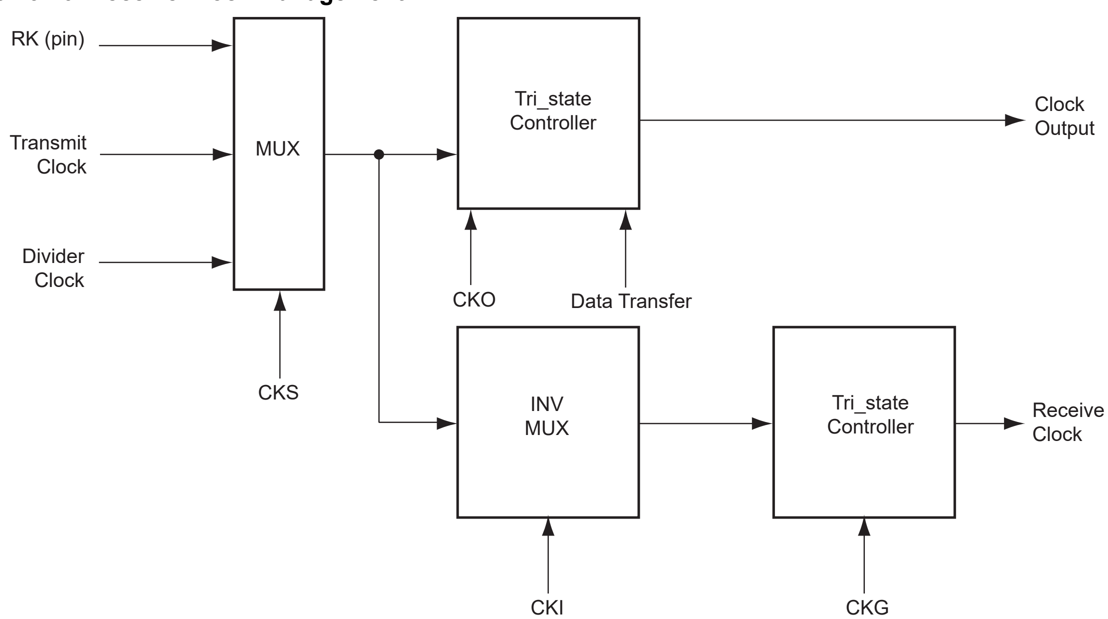


46.8.1.3 Receive Clock Management

The receive clock is generated from the transmit clock or the divider clock or an external clock scanned on the RK I/O pad. The Receive Clock is selected by the CKS field in SSC_RCMR (Receive Clock Mode Register). Receive Clocks can be inverted independently by the CKI bits in SSC_RCMR.

The receiver can also drive the RK I/O pad continuously or be limited to the current data transfer. The clock output is configured by the SSC_RCMR. The Receive Clock Inversion (CKI) bits have no effect on the clock outputs. Programming the SSC_RCMR to select RK pin (CKS field) and at the same time Continuous Receive Clock (CKO field) can lead to unpredictable results.

Figure 46-10. Receive Clock Management



46.8.1.4 Serial Clock Ratio Considerations

The transmitter and the receiver can be programmed to operate with the clock signals provided on either the TK or RK pins. This allows the SSC to support many Client mode data transfers. In this case, the maximum clock speed allowed on the RK pin is:

- Peripheral clock divided by 2 if Receive Frame Synchronization is input
- Peripheral clock divided by 3 if Receive Frame Synchronization is output

In addition, the maximum clock speed allowed on the TK pin is:

- Peripheral clock divided by 7 if Transmit Frame Synchronization is input
- Peripheral clock divided by 2 if Transmit Frame Synchronization is output

These are only theoretical speed limits for first order calculations. Refer to the section "Electrical Characteristics" for exact speed limits on TK and RK.

46.8.2 Transmit Operations

A transmit frame is triggered by a start event and can be followed by synchronization data before data transmission.

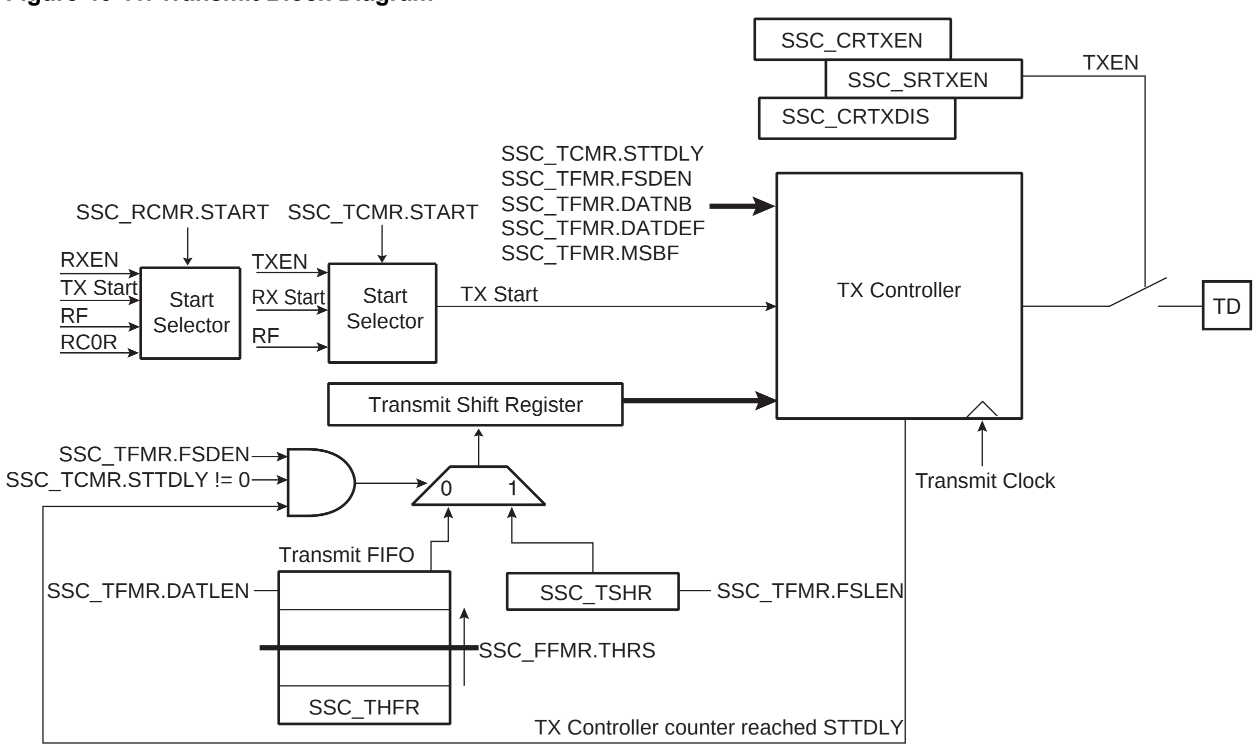
The start event is configured by setting the SSC_TCMR. See Start.

The frame synchronization is configured setting the Transmit Frame Mode Register (SSC_TFMR). See Frame Synchronization.

To transmit data, the transmitter uses a shift register clocked by the transmit clock signal and the start mode selected in the SSC_TCMR. Data are input by the application into the transmit FIFO by writing to the Transmit Holding FIFO register (SSC_THFR). Once the transmi t FIFO threshold programmed in the FIFO Mode register (SSC_FFMR.THRS) has been reached, data can be transferred to the transmit shift register according to the data format selected.

When both the transmit Holding FIFO and the transmit shift register are empty, the status flag TXEMPTY is set in the Status register (SSC_SR). As long as there is room left for writing new data into the transmit FIFO, the status flag TXRDY is set in the SSC_SR and additional data can be loaded in the Transmit Holding FIFO register. The number of remaining free data slots in the transmit FIFO is indicated by the SSC_SR.TXFRECNT field.

Figure 46-11. Transmit Block Diagram



46.8.3 Receive Operations

A receive frame is triggered by a start event and can be followed by synchronization data before data transmission.

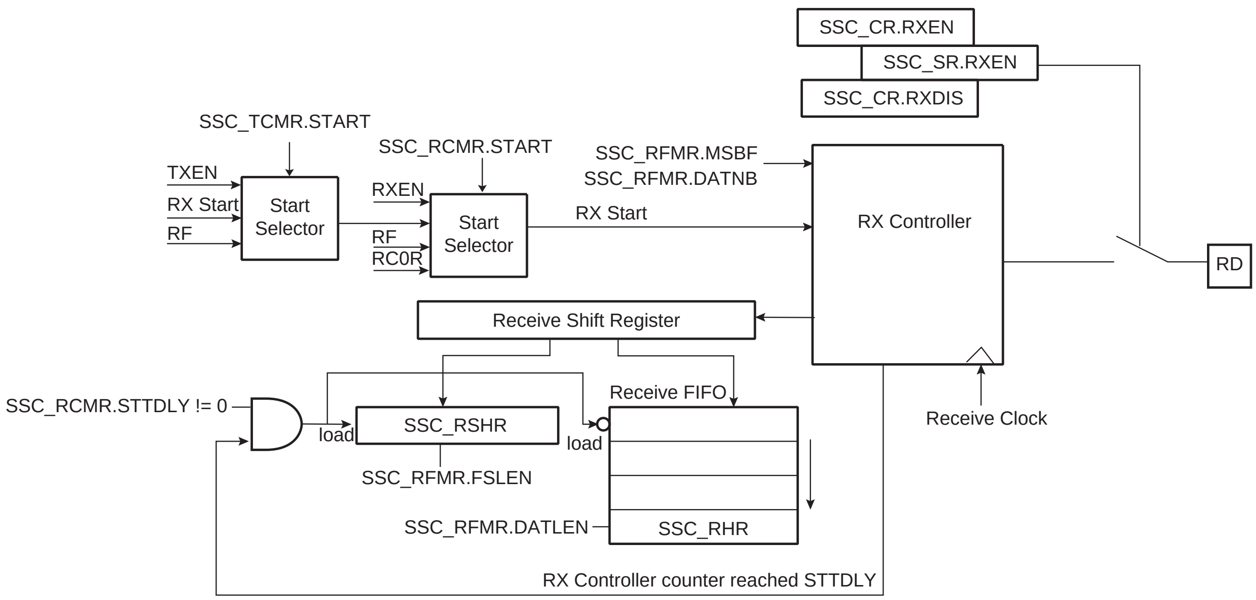
The start event is configured by setting the Receive Clock Mode Register (SSC_RCMR). See Start.

The frame synchronization is configured by setting the Receive Frame Mode Register (SSC_RFMR). See Frame Synchronization.

The receiver uses a shift register clocked by the receive clock signal and the start mode selected in the SSC_RCMR. The data is transferred from the shift register depending on the data format selected.

When the receive shift register is full, the SSC transfers the data into the receive FIFO, the status flag RXRDY is set in the SSC_SR and the data can be read in the Receive Holding FIFO register (SSC_RHFR). The number of remaining data words still to be read in the receive FIFO is indicated by the SSC_SR.RXURWCNT field. If a transfer occurs while the receive FIFO is full, the status flag OVRUN is set in the SSC_SR and the receive shift register is transferred in the receive FIFO. The oldest unread data is then lost.

Figure 46-12. Receive Block Diagram



46.8.4 Start

The transmitter and receiver can both be programmed to start their operations when an event occurs, respectively in the Transmit Start Selection (START) field of SSC_TCMR and in the Receive Start Selection (START) field of SSC_RCMR.

Under the following conditions the start event is independently programmable:

- Continuous. In this case, the transmission starts as soon as SSC_FFMR.THRS +1 words are written in SSC_THFR and the reception starts as soon as the receiver is enabled.
- Synchronously with the transmitter/receiver
- On detection of a falling/rising edge on TF/RF
- On detection of a low level/high level on TF/RF
- On detection of a level change or an edge on TF/RF

A start can be programmed in the same manner on either side of the Transmit/Receive Clock Register (SSC_RCMR/SSC_TCMR). Thus, the start could be on TF (Transmit) or RF (Receive).

Moreover, the receiver can start when data is detected in the bit stream with the Compare Functions.

Detection on TF/RF input/output is done by the field FSOS of the Transmit/Receive Frame Mode Register (SSC_TFMR/SSC_RFMR).

Figure 46-13. Transmit Start Mode

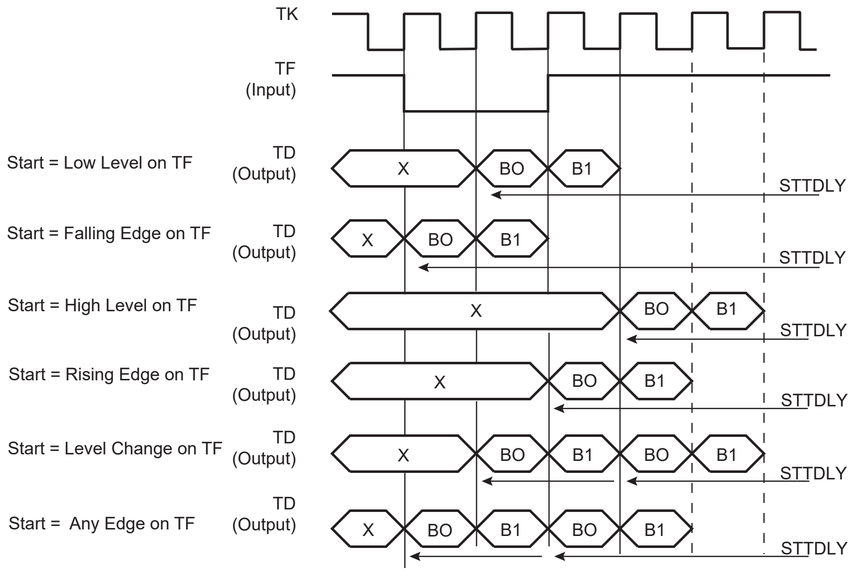


Figure 46-14. Receive Pulse/Edge Start Modes

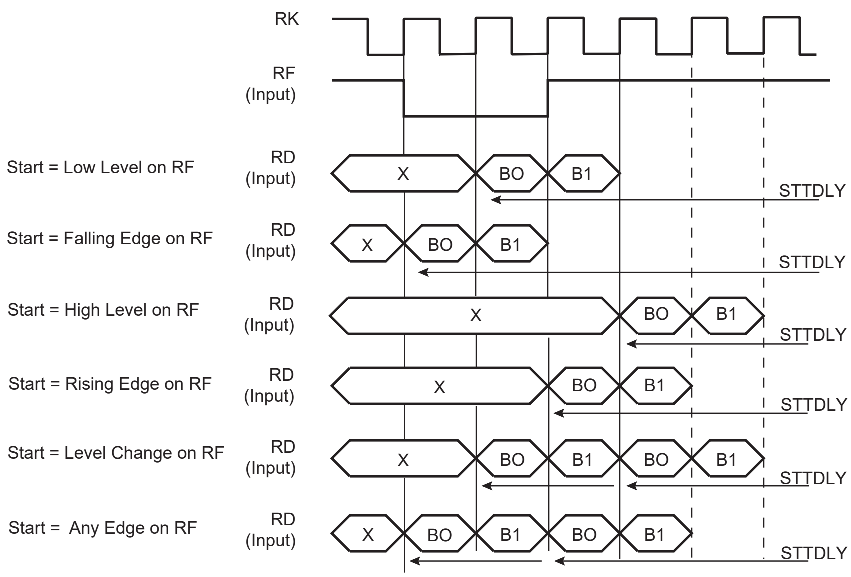


46.8.5 Frame Synchronization

The Transmit and Receive Frame Sync pins, TF and RF, can be programmed to generate different kinds of Frame Sync signals. The Frame Sync Output Selection (FSOS) field in the Receive Frame Mode Register (SSC_RFMR) and in the Transmit Frame Mode Register (SSC_TFMR) are used to select the required waveform.

- Programmable low or high levels during data transfer are supported.
- Programmable high levels before the start of data transfers or toggling are also supported.

If a pulse waveform is selected, the Frame Sync Length (FSLEN) field in SSC_RFMR and SSC_TFMR programs the length of the pulse, from 1 bit time up to 256 bit times.

The periodicity of the Receive and Transmit Frame Sync pulse output can be programmed through the Period Divider Selection (PERIOD) field in SSC_RCMR and SSC_TCMR.

46.8.5.1 Frame Sync Data

Frame Sync Data transmits or receives a specific tag during the Frame Sync signal.

During the Frame Sync signal, the receiver can sample the RD line and store the data in the Receive Sync Holding Register and the transmitter can transfer Transmit Sync Holding Register in the shift register. The data length to be sampled/shifted out during the Frame Sync signal is programmed by the FSLEN field in SSC_RFMR/SSC_TFMR and has a maximum value of 256.

Concerning the Receive Frame Sync Data operation, if the Frame Sync Length is equal to or lower than the delay between the start event and the current data reception, the data sampling operation is performed in the Receive Sync Holding Register through the receive shift register.

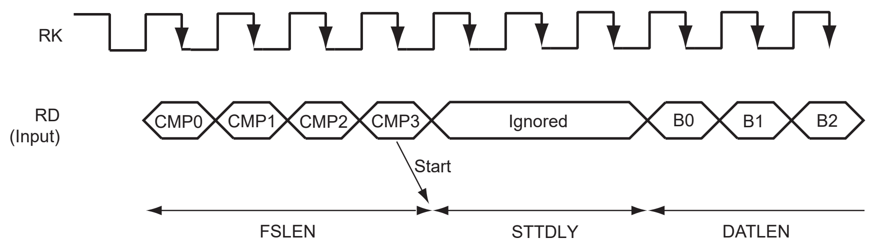
The Transmit Frame Sync Operation is performed by the transmitter only if the bit Frame Sync Data Enable (FSDEN) in SSC_TFMR is set. If the Frame Sync length is equal to or lower than the delay between the start event and the current data transmission, the normal transmission has priority and the data contained in the Transmit Sync Holding Register is transferred in the Transmit Register, then shifted out.

46.8.5.2 Frame Sync Edge Detection

The Frame Sync Edge detection is programmed by the FSEDGE field in SSC_RFMR/SSC_TFMR. This sets the corresponding flags RXSYN/TXSYN in the SSC Status Register (SSC_SR) on Frame Sync Edge detection (signals RF/TF).

46.8.6 Receive Compare Modes

Figure 46-15. Receive Compare Modes



46.8.6.1 Compare Functions

The length of the comparison patterns (Compare 0, Compare 1) and thus the number of bits they are compared to is defined by FSLEN, but with a maximum value of 256 bits. Comparison is always done by comparing the last bits received with the comparison pattern. Compare 0 can be one start event of the receiver. In this case, the receiver compares at each new sample the last bits received at the Compare 0 pattern contained in the Compare 0 Register (SSC_RC0R). When this start event is selected, the user can program the receiver to start a new data transfer either by writing a new Compare 0, or by receiving continuously until Compare 1 occurs. This selection is done with the STOP bit in the SSC_RCMR.

46.8.7 Data Format

The data framing format of both the transmitter and the receiver are programmable through the Transmitter Frame Mode Register (SSC_TFMR) and the Receive Frame Mode Register (SSC_RFMR). In either case, the user can independently select the following parameters:

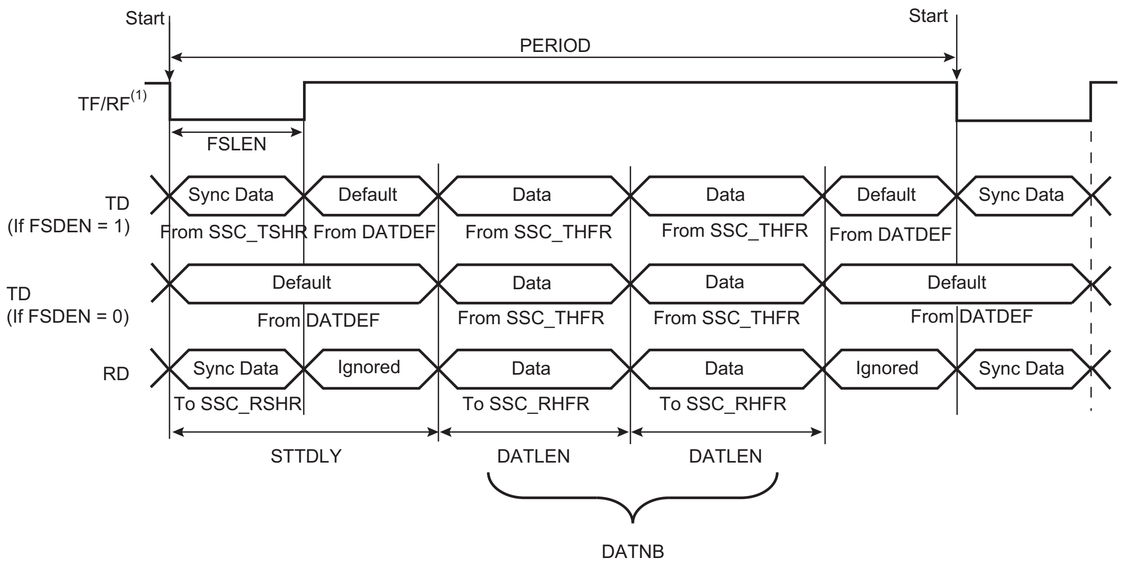
- Event that starts the data transfer (START)
- Delay in number of bit periods between the start event and the first data bit (STTDLY)
- Length of the data (DATLEN)
- Number of data to be transferred for each start event (DATNB)
- Length of synchronization transferred for each start event (FSLEN)
- Bit sense: most or least significant bit first (MSBF)

Additionally, the transmitter can be used to transfer synchronization and select the level driven on the TD pin while not in data transfer operation. This is done respectively by the Frame Sync Data Enable (FSDEN) and by the Data Default Value (DATDEF) bits in SSC_TFMR.

Table 46-2. Data Frame Registers

Transmitter	Receiver	Field	Length	Comment
SSC_TFMR	SSC_RFMR	DATLEN	Up to 32	Size of word
SSC_TFMR	SSC_RFMR	DATNB	Up to 16	Number of words transmitted in frame
SSC_TFMR	SSC_RFMR	MSBF	–	Most significant bit first
SSC_TFMR	SSC_RFMR	FSLEN	Up to 256	Size of Synchro data register
SSC_TFMR	–	DATDEF	0 or 1	Data default value ended
SSC_TFMR	–	FSDEN	–	Enable send SSC_TSHR
SSC_TCMR	SSC_RCMR	PERIOD	Up to 512	Frame size
SSC_TCMR	SSC_RCMR	STTDLY	Up to 255	Size of transmit start delay

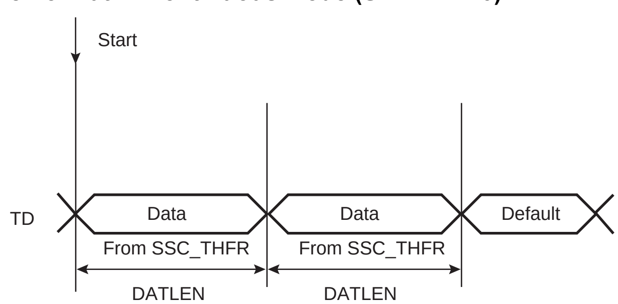
Figure 46-16. Transmit and Receive Frame Format in Edge/Pulse Start Modes



Note: 1. Example of input on falling edge of TF/RF.

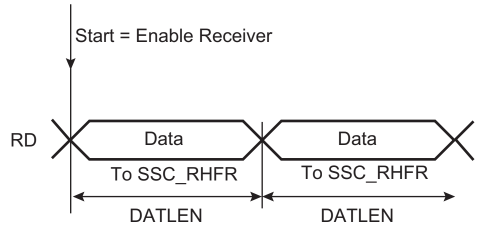
In the example illustrated above, the SSC_THFR is loaded twice. The FSDEN value has no effect on the transmission. SyncData cannot be output in Continuous mode.

Figure 46-17. Transmit Frame Format in Continuous Mode (STTDLY = 0)



Start: 1. TXEMPTY set to 1
2. Write into the SSC_THFR

Figure 46-18. Receive Frame Format in Continuous Mode (STTDLY = 0)



46.8.8 Loop Mode

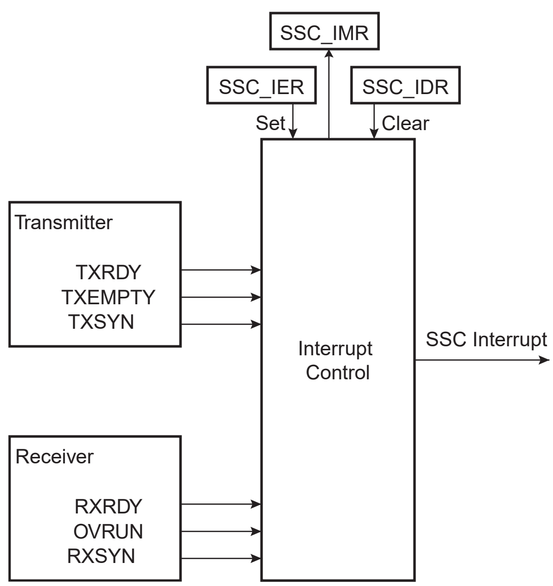
The receiver can be programmed to receive transmissions from the transmitter. This is done by setting the Loop Mode (LOOP) bit in the SSC_RFMR. In this case, RD is connected to TD, RF is connected to TF and RK is connected to TK.

46.8.9 Interrupt

Most bits in the SSC_SR have a corresponding bit in interrupt management registers.

The SSC can be programmed to generate an interrupt when it detects an event. The interrupt is controlled by writing the Interrupt Enable Register (SSC_IER) and Interrupt Disable Register (SSC_IDR). These registers enable and disable, respectively, the corresponding interrupt by setting and clearing the corresponding bit in the Interrupt Mask Register (SSC_IMR), which controls the generation of interrupts by asserting the SSC interrupt line connected to the interrupt controller.

Figure 46-19. Interrupt Block Diagram



46.8.10 Register Write Protection

To prevent any single software error from corrupting SSC behavior, certain registers in the address space can be write-protected by setting the WPEN bit in the SSC Write Protection Mode Register (SSC_WPMR).

If a write access to a write-protected register is detected, the WPVS flag in the SSC Write Protection Status Register (SSC_WPSR) is set and the field WPVSRC indicates the register in which the write access has been attempted.

The WPVS bit is automatically cleared after reading the SSC_WPSR.

The following registers can be write-protected:

- SSC Clock Mode Register
- SSC Receive Clock Mode Register
- SSC Receive Frame Mode Register

- SSC Transmit Clock Mode Register
- SSC Transmit Frame Mode Register
- SSC Receive Compare 0 Register
- SSC Receive Compare 1 Register

46.9 Register Summary

Note: Offsets 0x100–0x128 are reserved for PDC registers.

46.9.1 SSC Control Register

Name: SSC_CR
Offset: 0x0
Reset: –
Property: Write-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
	SWRST						TXDIS	TXEN
Access	W						W	W
Reset	–						–	–

Bit	7	6	5	4	3	2	1	0
							RXDIS	RXEN
Access							W	W
Reset							–	–

Bit 15 – SWRST Software Reset

Value	Description
0	No effect.
1	Performs a software reset. Has priority on any other bit in SSC_CR.

Bit 9 – TXDIS Transmit Disable

Value	Description
0	No effect.
1	Disables Transmit. If a character is currently being transmitted, disables at end of current character transmission.

Bit 8 – TXEN Transmit Enable

Value	Description
0	No effect.
1	Enables Transmit if TXDIS is not set.

Bit 1 – RXDIS Receive Disable

Value	Description
0	No effect.
1	Disables Receive. If a character is currently being received, disables at end of current character reception.

Bit 0 – RXEN Receive Enable

Value	Description
0	No effect.
1	Enables Receive if RXDIS is not set.

46.9.2 SSC Clock Mode Register

Name: SSC_CMR
Offset: 0x4
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the SSC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0

Bits 11:0 – DIV[11:0] Clock Divider

Value	Description
0	The Clock Divider is not active.
Any other value	The divided clock equals the peripheral clock divided by 2 times DIV. The maximum bit rate is $f_{peripheral\ clock}/2$. The minimum bit rate is $f_{peripheral\ clock}/2 \times 4095 = f_{peripheral\ clock}/8190$.

46.9.3 SSC Receive Clock Mode Register

Name: SSC_RCMR
Offset: 0x10
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the SSC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
	PERIOD[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 31:24 – PERIOD[7:0] Receive Period Divider Selection
This field selects the divider to apply to the selected Receive Clock in order to generate a new Frame Sync signal. If 0, no PERIOD signal is generated. If not 0, a PERIOD signal is generated each 2 x (PERIOD + 1) Receive Clock.

Bits 23:16 – STTDLY[7:0] Receive Start Delay
If STTDLY is not 0, a delay of STTDLY clock cycles is inserted between the start event and the current start of reception. When the receiver is programmed to start synchronously with the transmitter, the delay is also applied.
Note: STTDLY must be configured in relation to the receive synchronization data to be stored in SSC_RSHR.

Bit 12 – STOP Receive Stop Selection

Value	Description
0	After completion of a data transfer when starting with a Compare 0, the receiver stops the data transfer and waits for a new compare 0.
1	After starting a receive with a Compare 0, the receiver operates in a continuous mode until a Compare 1 is detected.

Bits 11:8 – START[3:0] Receive Start Selection

Value	Name	Description
0	CONTINUOUS	Continuous, as soon as the receiver is enabled, and immediately after the end of transfer of the previous data.
1	TRANSMIT	Transmit start
2	RF_LOW	Detection of a low level on RF signal
3	RF_HIGH	Detection of a high level on RF signal
4	RF_FALLING	Detection of a falling edge on RF signal
5	RF_RISING	Detection of a rising edge on RF signal
6	RF_LEVEL	Detection of any level change on RF signal
7	RF_EDGE	Detection of any edge on RF signal
8	CMP_0	Compare 0

Bits 7:6 – CKG[1:0] Receive Clock Gating Selection

Value	Name	Description
0	CONTINUOUS	None
1	EN_RF_LOW	Receive Clock enabled only if RF Low
2	EN_RF_HIGH	Receive Clock enabled only if RF High

Bit 5 – CKI Receive Clock Inversion

CKI affects only the Receive Clock and not the output clock signal.

Value	Description
0	The data inputs (Data and Frame Sync signals) are sampled on Receive Clock falling edge. The Frame Sync signal output is shifted out on Receive Clock rising edge.
1	The data inputs (Data and Frame Sync signals) are sampled on Receive Clock rising edge. The Frame Sync signal output is shifted out on Receive Clock falling edge.

Bits 4:2 – CKO[2:0] Receive Clock Output Mode Selection

Value	Name	Description
0	NONE	None, RK pin is an input
1	CONTINUOUS	Continuous Receive Clock, RK pin is an output
2	TRANSFER	Receive Clock only during data transfers, RK pin is an output

Bits 1:0 – CKS[1:0] Receive Clock Selection

Value	Name	Description
0	MCK	Divided Clock
1	TK	TK Clock signal
2	RK	RK pin

46.9.4 SSC Receive Frame Mode Register

Name: SSC_RFMR
Offset: 0x14
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the SSC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
	FSLEN_EXT[3:0]							FSEDGE
Access	R/W	R/W	R/W	R/W				R/W
Reset	0	0	0	0				0

Bit	23	22	21	20	19	18	17	16
		FSOS[2:0]			FSLEN[3:0]			
Access		R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset		0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
					DATNB[3:0]			
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bit	7	6	5	4	3	2	1	0
	MSBF		LOOP	DATLEN[4:0]				
Access	R/W		R/W	R/W	R/W	R/W	R/W	R/W
Reset	0		0	0	0	0	0	0

Bits 31:28 – FSLEN_EXT[3:0] FSLEN Field Extension
Extends FSLEN field. For details, see FSLEN: Receive Frame Sync Length.

Bit 24 – FSEDGE Frame Sync Edge Detection
Determines which edge on Frame Sync will generate the interrupt RXSYN in the SSC Status Register.

Value	Name	Description
0	POSITIVE	Positive Edge Detection
1	NEGATIVE	Negative Edge Detection

Bits 22:20 – FSOS[2:0] Receive Frame Sync Output Selection

Value	Name	Description
0	NONE	None, RF pin is an input
1	NEGATIVE	Negative Pulse, RF pin is an output
2	POSITIVE	Positive Pulse, RF pin is an output
3	LOW	Driven Low during data transfer, RF pin is an output
4	HIGH	Driven High during data transfer, RF pin is an output
5	TOGGLING	Toggling at each start of data transfer, RF pin is an output

Bits 19:16 – FSLEN[3:0] Receive Frame Sync Length
This field defines the number of bits sampled and stored in the Receive Sync Data Register. When this mode is selected by the START field in the Receive Clock Mode Register, it also determines the length of the sampled data to be compared to the Compare 0 or Compare 1 register.
This field is used with FSLEN_EXT to determine the pulse length of the Receive Frame Sync signal.
Pulse length is equal to FSLEN + (FSLEN_EXT × 16) + 1 Receive Clock periods.

Bits 11:8 – DATNB[3:0] Data Number per Frame
This field defines the number of data words to be received after each transfer start, which is equal to (DATNB + 1).

Bit 7 – MSBF Most Significant Bit First

Value	Description
0	The lowest significant bit of the data register is sampled first in the bit stream.
1	The most significant bit of the data register is sampled first in the bit stream.

Bit 5 – LOOP Loop Mode

Value	Description
0	Normal operating mode.
1	RD is driven by TD, RF is driven by TF and TK drives RK.

Bits 4:0 – DATLEN[4:0] Data Length

Value	Description
0	Forbidden value (1-bit data length not supported).
Any other value	The bit stream contains DATLEN + 1 data bits.

46.9.5 SSC Transmit Clock Mode Register

Name: SSC_TCMR
Offset: 0x18
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the SSC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
	PERIOD[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0
Bit	23	22	21	20	19	18	17	16
	STTDLY[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8
					START[3:0]			
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0
Bit	7	6	5	4	3	2	1	0
	CKG[1:0]		CKI	CKO[2:0]			CKS[1:0]	
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 31:24 – PERIOD[7:0] Transmit Period Divider Selection
This field selects the divider to apply to the selected Transmit Clock to generate a new Frame Sync signal. If 0, no period signal is generated. If not 0, a period signal is generated at each 2 × (PERIOD + 1) Transmit Clock.

Bits 23:16 – STTDLY[7:0] Transmit Start Delay
If STTDLY is not 0, a delay of STTDLY clock cycles is inserted between the start event and the current start of transmission of data. When the transmitter is programmed to start synchronously with the receiver, the delay is also applied.
Note:
If STTDLY is too short with respect to transmit synchronization data (SSC_TSHR), SSC_THR.TDAT is transmitted instead of the end of SSC_TSHR.

Bits 11:8 – START[3:0] Transmit Start Selection

Value	Name	Description
0	CONTINUOUS	Continuous, as soon as a word is written in the SSC_THR (if Transmit is enabled), and immediately after the end of transfer of the previous data
1	RECEIVE	Receive start
2	TF_LOW	Detection of a low level on TF signal
3	TF_HIGH	Detection of a high level on TF signal
4	TF_FALLING	Detection of a falling edge on TF signal
5	TF_RISING	Detection of a rising edge on TF signal
6	TF_LEVEL	Detection of any level change on TF signal
7	TF_EDGE	Detection of any edge on TF signal

Bits 7:6 – CKG[1:0] Transmit Clock Gating Selection

Value	Name	Description
0	CONTINUOUS	None
1	EN_TF_LOW	Transmit Clock enabled only if TF Low

Value	Name	Description
2	EN_TF_HIGH	Transmit Clock enabled only if TF High

Bit 5 – CKI Transmit Clock Inversion
CKI affects only the Transmit Clock and not the Output Clock signal.

Value	Description
0	The data outputs (Data and Frame Sync signals) are shifted out on Transmit Clock falling edge. The Frame Sync signal input is sampled on Transmit Clock rising edge.
1	The data outputs (Data and Frame Sync signals) are shifted out on Transmit Clock rising edge. The Frame Sync signal input is sampled on Transmit Clock falling edge.

Bits 4:2 – CKO[2:0] Transmit Clock Output Mode Selection

Value	Name	Description
0	NONE	None, TK pin is an input
1	CONTINUOUS	Continuous Transmit Clock, TK pin is an output
2	TRANSFER	Transmit Clock only during data transfers, TK pin is an output

Bits 1:0 – CKS[1:0] Transmit Clock Selection

Value	Name	Description
0	MCK	Divided Clock
1	RK	RK Clock signal
2	TK	TK pin

46.9.6 SSC Transmit Frame Mode Register

Name: SSC_TFMR
Offset: 0x1C
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the SSC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
	FSLEN_EXT[3:0]							FSEDGE
Access	R/W	R/W	R/W	R/W				R/W
Reset	0	0	0	0				0

Bit	23	22	21	20	19	18	17	16
	FSDEN	FSOS[2:0]			FSLEN[3:0]			
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
					DATNB[3:0]			
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bit	7	6	5	4	3	2	1	0
	MSBF		DATDEF	DATLEN[4:0]				
Access	R/W		R/W	R/W	R/W	R/W	R/W	R/W
Reset	0		0	0	0	0	0	0

Bits 31:28 – FSLEN_EXT[3:0] FSLEN Field Extension
Extends FSLEN field. For details, see FSLEN description below.

Bit 24 – FSEDGE Frame Sync Edge Detection
Determines which edge on frame synchronization will generate the interrupt TXSYN (Status Register).

Value	Name	Description
0	POSITIVE	Positive Edge Detection
1	NEGATIVE	Negative Edge Detection

Bit 23 – FSDEN Frame Sync Data Enable

Value	Description
0	The TD line is driven with the default value during the Transmit Frame Sync signal.
1	SSC_TSHR value is shifted out during the transmission of the Transmit Frame Sync signal.

Bits 22:20 – FSOS[2:0] Transmit Frame Sync Output Selection

Value	Name	Description
0	NONE	None, TF pin is an input
1	NEGATIVE	Negative Pulse, TF pin is an output
2	POSITIVE	Positive Pulse, TF pin is an output
3	LOW	Driven Low during data transfer
4	HIGH	Driven High during data transfer
5	TOGGLING	Toggling at each start of data transfer

Bits 19:16 – FSLEN[3:0] Transmit Frame Sync Length
This field defines the length of the Transmit Frame Sync signal and the number of bits shifted out from SSC_TSHR if FSDEN is 1.
This field is used with FSLEN_EXT to determine the pulse length of the Transmit Frame Sync signal.
Pulse length is equal to FSLEN + (FSLEN_EXT × 16) + 1 Transmit Clock period.

Bits 11:8 – DATNB[3:0] Data Number per Frame
This field defines the number of data words to be transferred after each transfer start, which is equal to (DATNB + 1).

Bit 7 – MSBF Most Significant Bit First

Value	Description
0	The lowest significant bit of the data register is shifted out first in the bit stream.
1	The most significant bit of the data register is shifted out first in the bit stream.

Bit 5 – DATDEF Data Default Value
This bit defines the level driven on the TD pin while out of transmission. Note that if the pin is defined as multi-drive by the PIO Controller, the pin is enabled only if the SCC TD output is 1.
When the TD pin is configured in Multi-drive (Open-drain) mode by the PIO controller, a 0 is driven if SSC data output equals 0 and the pin is in high-impedance when SSC data output is 1.

Bits 4:0 – DATLEN[4:0] Data Length

Value	Description
0	Forbidden value (1-bit data length not supported).
Any other value	The bit stream contains DATLEN + 1 data bits.

46.9.7 SSC Receive Holding FIFO Register

Name: SSC_RHFR
Offset: 0x20
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
	RDAT[31:24]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	RDAT[23:16]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	RDAT[15:8]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	RDAT[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bits 31:0 – RDAT[31:0] Receive Data
Right-aligned regardless of the number of data bits defined by SSC_RFMR.DATLEN.

46.9.8 SSC Transmit Holding FIFO Register

Name: SSC_THFR
Offset: 0x24
Reset: –
Property: Write-only

Bit	31	30	29	28	27	26	25	24
	TDAT[31:24]							
Access	W	W	W	W	W	W	W	W
Reset	–	–	–	–	–	–	–	–

Bit	23	22	21	20	19	18	17	16
	TDAT[23:16]							
Access	W	W	W	W	W	W	W	W
Reset	–	–	–	–	–	–	–	–

Bit	15	14	13	12	11	10	9	8

Access	W	W	W	W	W	W	W	W
Reset	–	–	–	–	–	–	–	–

Bit	7	6	5	4	3	2	1	0
	TDAT[7:0]							
Access	W	W	W	W	W	W	W	W
Reset	–	–	–	–	–	–	–	–

Bits 31:0 – TDAT[31:0] Transmit Data
Right-aligned regardless of the number of data bits defined by SSC_TFMR.DATLEN.

46.9.9 SSC FIFO Mode Register

Name: SSC_FFMR
Offset: 0x28
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the SSC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								
Bit	**23**	**22**	**21**	**20**	**19**	**18**	**17**	**16**

								TXFIFODIS
Access								R/W
Reset								0

Bit 16 – RXFIFODIS Receive FIFO Disable

Value	Description
0	The receive FIFO is enabled.
1	The receive FIFO is disabled. Only a single entry Receive Holding register is available instead.

Bits 11:8 – THRS[3:0] Transmit Start Threshold
Number of additional data to be written into SCC_THFR prior to loading the first data into the Transmit Shift register.
0 means the first data written into SCC_THFR is immediately loaded into the Shift register.
7 means the loading into SSC_THFR will occur only when the transmit FIFO is full.

Bit 0 – TXFIFODIS Transmit FIFO Disable

Value	Description
0	The transmit FIFO is enabled.
1	The transmit FIFO is disabled. Only a single entry Transmit Holding register is available instead.

46.9.10 SSC Receive Synchronization Holding Register

Name: SSC_RSHR
Offset: 0x30
Reset: 0x00000000
Property: Read-only

46.9.14 SSC Status Register

Name: SSC_SR
Offset: 0x40
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
	RXURWCNT[3:0]				TXFRECNT[3:0]			
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
							RXEN	TXEN
Access							R	R
Reset							0	0

Bit	15	14	13	12	11	10	9	8
					RXSYN	TXSYN	CP1	CP0
Access					R	R	R	R
Reset					0	0	0	0

Bit	7	6	5	4	3	2	1	0
			OVRUN	RXRDY			TXEMPTY	TXRDY
Access			R	R			R	R
Reset			0	0			0	0

Bits 31:28 – RXURWCNT[3:0] Receive FIFO Unread Word Count
Number of received data words in the receive FIFO still to be read from SSC_RHFR.
This counter is incremented upon each load of the receive FIFO with a data from the receive shifter and decremented by each data read from SSC_RHFR.

Bits 27:24 – TXFRECNT[3:0] Transmit FIFO Free Entries Count
Number of free data entries in the transmit FIFO that can be written into SSC_THFR.
This counter is decremented by each data write into SSC_THFR and incremented upon each transfer of a transmit FIFO data into the transmit shifter.

Bit 17 – RXEN Receive Enable

Value	Description
0	Receive is disabled.
1	Receive is enabled.

Bit 16 – TXEN Transmit Enable

Value	Description
0	Transmit is disabled.
1	Transmit is enabled.

Bit 11 – RXSYN Receive Sync

Value	Description
0	An Rx Sync has not occurred since the last read of the Status register.
1	An Rx Sync has occurred since the last read of the Status register.

Bit 10 – TXSYN Transmit Sync

Value	Description
0	A Tx Sync has not occurred since the last read of the Status register.
1	A Tx Sync has occurred since the last read of the Status register.

Bit 9 – CP1 Compare 1

Value	Description
0	A compare 1 has not occurred since the last read of the Status register.
1	A compare 1 has occurred since the last read of the Status register.

Bit 8 – CP0 Compare 0

Value	Description
0	A compare 0 has not occurred since the last read of the Status register.
1	A compare 0 has occurred since the last read of the Status register.

Bit 5 – OVRUN Receive Overrun

Value	Description
0	No data has been loaded in SSC_RHR while previous data has not been read since the last read of the Status Register.
1	Data has been loaded in SSC_RHR while previous data has not yet been read since the last read of the Status Register.

Bit 4 – RXRDY Receive Ready

Value	Description
0	SSC_RHR is empty.
1	Data has been received and loaded in SSC_RHR.

Bit 1 – TXEMPTY Transmit Empty

Value	Description
0	Data remains in SSC_THR or is currently transmitted from TSR.
1	Last data written in SSC_THR has been loaded in TSR and last data loaded in TSR has been transmitted.

Bit 0 – TXRDY Transmit Ready

Value	Description
0	Data has been loaded in SSC_THR and is waiting to be loaded in the Transmit Shift register (TSR).
1	SSC_THR is empty.

46.9.15 SSC Interrupt Enable Register

Name: SSC_IER
Offset: 0x44
Reset: –
Property: Write-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
					RXSYN	TXSYN	CP1	CP0
Access					W	W	W	W
Reset					–	–	–	–

Bit	7	6	5	4	3	2	1	0
			OVRUN	RXRDY			TXEMPTY	TXRDY
Access			W	W			W	W
Reset			–	–			–	–

Bit 11 – RXSYN Rx Sync Interrupt Enable

Value	Description
0	No effect.
1	Enables the Rx Sync Interrupt.

Bit 10 – TXSYN Tx Sync Interrupt Enable

Value	Description
0	No effect.
1	Enables the Tx Sync Interrupt.

Bit 9 – CP1 Compare 1 Interrupt Enable

Value	Description
0	No effect.
1	Enables the Compare 1 Interrupt.

Bit 8 – CP0 Compare 0 Interrupt Enable

Value	Description
0	No effect.
1	Enables the Compare 0 Interrupt.

Bit 5 – OVRUN Receive Overrun Interrupt Enable

Value	Description
0	No effect.
1	Enables the Receive Overrun Interrupt.

Bit 4 – RXRDY Receive Ready Interrupt Enable

Value	Description
0	No effect.

Value	Description
1	Enables the Receive Ready Interrupt.

Bit 1 – TXEMPTY Transmit Empty Interrupt Enable

Value	Description
0	No effect.
1	Enables the Transmit Empty Interrupt.

Bit 0 – TXRDY Transmit Ready Interrupt Enable

Value	Description
0	No effect.
1	Enables the Transmit Ready Interrupt.

46.9.16 SSC Interrupt Disable Register

Name: SSC_IDR
Offset: 0x48
Reset: –
Property: Write-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8

			OVRUN	RXRDY			TXEMPTY	TXRDY
Access			W	W			W	W
Reset			–	–			–	–

Bit 11 – RXSYN Rx Sync Interrupt Enable

Value	Description
0	No effect.
1	Disables the Rx Sync Interrupt.

Bit 10 – TXSYN Tx Sync Interrupt Enable

Value	Description
0	No effect.
1	Disables the Tx Sync Interrupt.

Bit 9 – CP1 Compare 1 Interrupt Disable

Value	Description
0	No effect.
1	Disables the Compare 1 Interrupt.

Bit 8 – CP0 Compare 0 Interrupt Disable

Value	Description
0	No effect.
1	Disables the Compare 0 Interrupt.

Bit 5 – OVRUN Receive Overrun Interrupt Disable

Value	Description
0	No effect.
1	Disables the Receive Overrun Interrupt.

Bit 4 – RXRDY Receive Ready Interrupt Disable

Value	Description
0	No effect.

Value	Description
1	Disables the Receive Ready Interrupt.

Bit 1 – TXEMPTY Transmit Empty Interrupt Disable

Value	Description
0	No effect.
1	Disables the Transmit Empty Interrupt.

Bit 0 – TXRDY Transmit Ready Interrupt Disable

Value	Description
0	No effect.
1	Disables the Transmit Ready Interrupt.

46.9.17 SSC Interrupt Mask Register

Name: SSC_IMR
Offset: 0x4C
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access

Bit 11 – RXSYN Rx Sync Interrupt Mask

Value	Description
0	The Rx Sync Interrupt is disabled.
1	The Rx Sync Interrupt is enabled.

Bit 10 – TXSYN Tx Sync Interrupt Mask

Value	Description
0	The Tx Sync Interrupt is disabled.
1	The Tx Sync Interrupt is enabled.

Bit 9 – CP1 Compare 1 Interrupt Mask

Value	Description
0	The Compare 1 Interrupt is disabled.
1	The Compare 1 Interrupt is enabled.

Bit 8 – CP0 Compare 0 Interrupt Mask

Value	Description
0	The Compare 0 Interrupt is disabled.
1	The Compare 0 Interrupt is enabled.

Bit 5 – OVRUN Receive Overrun Interrupt Mask

Value	Description
0	The Receive Overrun Interrupt is disabled.
1	The Receive Overrun Interrupt is enabled.

Bit 4 – RXRDY Receive Ready Interrupt Mask

Value	Description
0	The Receive Ready Interrupt is disabled.

Value	Description
1	The Receive Ready Interrupt is enabled.

Bit 1 – TXEMPTY Transmit Empty Interrupt Mask

Value	Description
0	The Transmit Empty Interrupt is disabled.
1	The Transmit Empty Interrupt is enabled.

Bit 0 – TXRDY Transmit Ready Interrupt Mask

Value	Description
0	The Transmit Ready Interrupt is disabled.
1	The Transmit Ready Interrupt is enabled.

46.9.18 SSC Write Protection Mode Register

Name: SSC_WPMR
Offset: 0xE4
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
	WPKEY[23:16]							
Access	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
								WPEN
Access								R/W
Reset								0

Bits 31:8 – WPKEY[23:0] Write Protection Key

Value	Name	Description
0x535343	PASSWD	Writing any other value in this field aborts the write operation of the WPEN bit. Always reads as 0.

Bit 0 – WPEN Write Protection Enable
See Register Write Protection for the list of registers that can be protected.

Value	Description
0	Disables the write protection if WPKEY corresponds to 0x535343 (“SSC” in ASCII).
1	Enables the write protection if WPKEY corresponds to 0x535343 (“SSC” in ASCII).

46.9.19 SSC Write Protection Status Register

Name: SSC_WPSR
Offset: 0xE8
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24

Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
								WPVS
Access								R
Reset								0

Bits 23:8 – WPVSRC[15:0] Write Protect Violation Source
When WPVS = 1, WPVSRC indicates the register address offset at which a write access has been attempted.

Bit 0 – WPVS Write Protection Violation Status

Value	Description
0	No write protection violation has occurred since the last read of the SSC_WPSR.
1	A write protection violation has occurred since the last read of the SSC_WPSR. If this violation is an unauthorized attempt to write a protected register, the associated violation is reported into field WPVSRC.

47. Sony/Philips Digital Interface Receiver (SPDIFRX)

47.1 Description

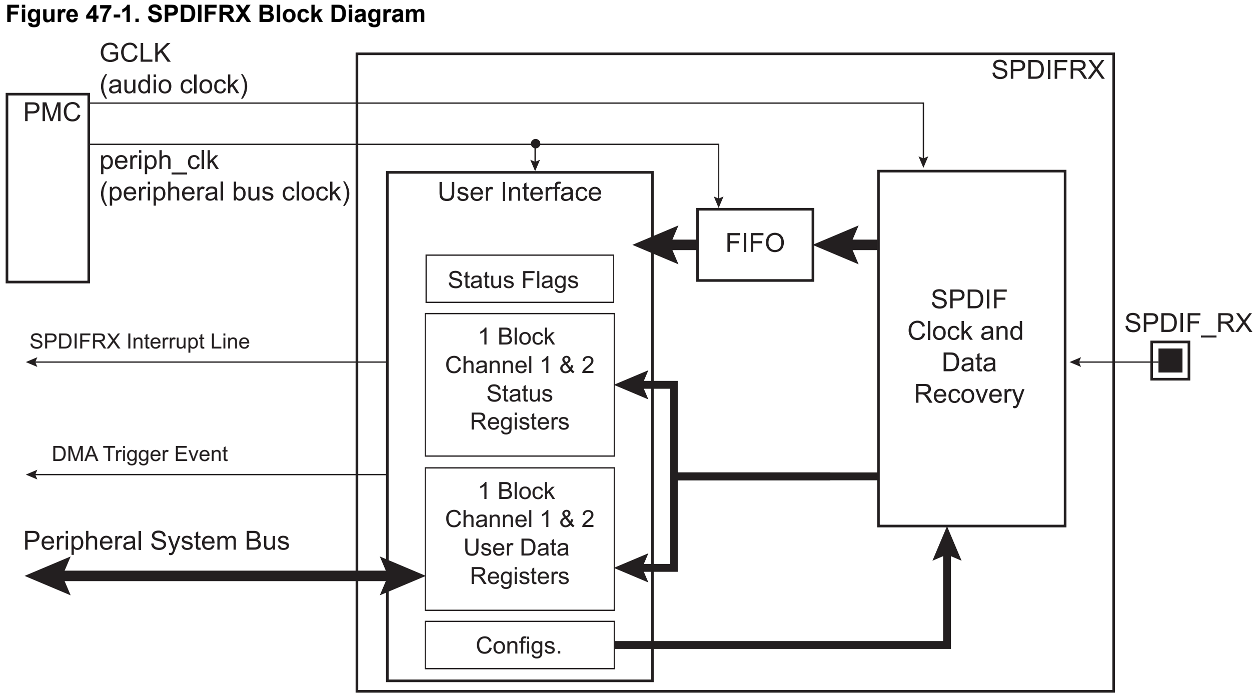
The Sony/Philips Digital Interface Receiver (SPDIFRX) is a serial port compliant with the IEC-60958 standard.

47.2 Embedded Characteristics

- SPDIF/AES-EBU Compatible Serial Port
- 32 Samples FIFO
- Data Width Configurable to 24 bits, 20 bits or 16 bits
- Packed and Unpacked Data Support for System Memory Optimization
- Line State Events Report and Source of Interrupt
- Line Error Rate Report
- Full Memory Map of 192 bits for Channel 1 and Channel 2 Status and User Data
- First 32-bit Status A, Status B Change Report and Source of Interrupt
- Line Digital Filter
- Register Write Protection
- Abnormal Software Access and Internal Sequencer Integrity Check Reports

47.3 Block Diagram

Figure 47-1. SPDIFRX Block Diagram



47.4 Signal Description

Table 47-1. Pin Description

Pin Name	Description	Direction
SPDIF_RX	SPDIF Receive Line	Input

47.5 Product Dependencies

47.5.1 I/O Lines

The pins used for interfacing the compliant external devices can be multiplexed with PIO lines. The programmer must first program the PIO controllers to assign the SPDIF pin to their peripheral functions.

47.5.2 Power Management

The SPDIFRX is clocked through the Power Management Controller (PMC), thus the programmer must first configure the PMC to enable the SPDIFRX clocks.

47.5.3 Interrupt Sources

The SPDIFRX interface has an interrupt line connected to the interrupt controller. Handling the SPDIFRX interrupt requires programming the interrupt controller before configuring the SPDIFRX.

47.6 Functional Description

47.6.1 Protocol

The SPDIFRX protocol is defined in IEC-60958 standard.

Data is performed by the transfer of blocks of 192 frames.

Each frame is divided into two subframes, one for each channel.

Each subframe is divided into 32 time slots carrying the following fields:

- Preamble (4 bits)–Three possible preambles named B, M and W. Preambles are specific patterns providing synchronization and identification of the subframes and blocks.
- Data (24 bits)–Can carry a PCM audio data or non-PCM data streams.
- Validity bit
- User data bit
- Channel status bit
- Parity bit–Ensures that time slots 4 to 31 carry an even number of ones and an even number of zeros.

Note: The data field may carry 16-bit, 20-bit or 24-bit data.

Figure 47-2. SPDIFRX Frame and Block Format

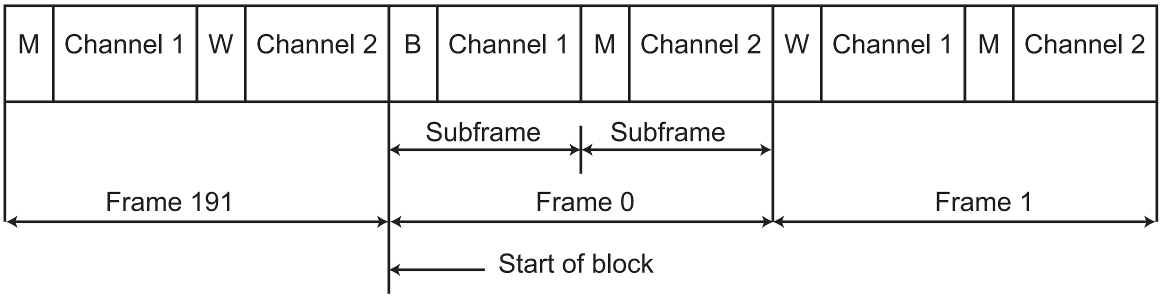


Figure 47-3. SPDIFRX Subframe Format

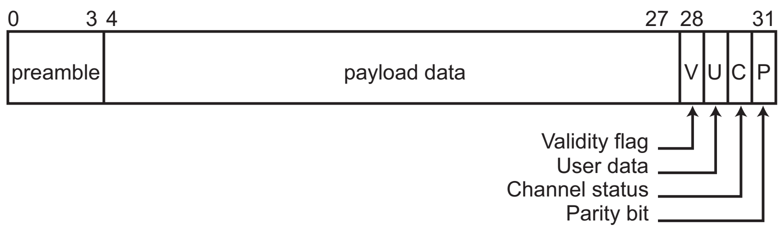


47.6.2 Data Rate

The SPDIFRX operates at the frequency of generic clock (GCLK) input clock (typically the audio clock). The GCLK clock frequency must be greater than 768 × f_S (12 × 64 × f_S). For example, 192 kHz sampling frequency can be recovered if the GCLK clock frequency is 150 MHz and above, and f_S = 48 kHz can be recovered if the GCLK clock frequency is above 38 MHz.

47.6.3 Clock and Data Recovery

When the SPDIFRX is first enabled by writing a '1' in the bit RXEN in the Mode register (SPDIFRX_MR), the bit ULOCK in the Receiver Status register (SPDIFRX_RSR) is set, indicating that the synchronization of the receiver circuitry with the received stream is in progress. The SPDIFRX_RSR.ULOCK=1 if no synchronization is possible.

If there is no signal (no detection of falling/rising edges) on the SPDIF_RX line, the bit SPDIFRX_RSR.NOSIGNAL='1'.

If the SPDIF_RX line carries an SPDIF signal having a sampling frequency which does not meet the criteria defined in 47.6.2. Data Rate, the bit SPDIFRX_RSR.LOWF= '1'.

If a non-SPDIF format is received/detected, the bit SPDIFRX_RSR.BADF= '1'. A non-SPDIF format is detected when the width of the larger pulse (located in preamble area) is not higher than 2.5 times the width of the minimum pulse or is greater than 4 times the width of the minimum pulse.

As soon as a valid SPDIF format is detected, the clock recovery circuitry is locked and the bi-mark data is decoded and the circuitry searches for predefined preamble values.

Once one of the preamble values is found, SPDIFRX_RSR.ULOCK is cleared and the bit LOCKED in the Interrupt Status register (SPDIFRX_ISR) is set to '1'. An interrupt can be triggered if LOCKED in the Interrupt Enable register (SPDIFRX_IER) is written to '1'.

The SPDIF_RX line is filtered by a digital filter to reduce noise before clock recovery. Any pulse with width lower than or equal to one GCLK clock period is eliminated.

The maximum lock time is 1.5 sample periods (1.5 frames). As soon as SPDIFRX_RSR.ULOCK is cleared, the payload data is stored in the FIFO and the channel 1 and 2 status bits and user data bits are stored. At the end of each block (192 frames), the bit SPDIFRX_ISR.BLOCKEND is set to '1'. If the SPDIFRX_ISR.BLOCKEND=1, the content of channel status (SPDIFRX_CH1SRx[x=0..5], SPDIFRX_CH2SRx[x=0..5]) and user data (SPDIFRX_CH1UDRx[x=0..5], SPDIFRX_CH2UDRx[x=0..5]) registers is valid.

When locked, in case of a loss of signal (32 consecutive 0's or 1's), the flag SPDIFRX_ISR.LOSS is set to '1' and the recovery circuitry searches again for a synchronization pattern. When unlocked (SPDIFRX_RSR.ULOCK=1) the bit SPDIFRX_RSR.NOSIGNAL is set to '1'.

Several error types are monitored and reported in the SPDIFRX_ISR:
- If the flag SPDIFRX_ISR.PAR_ERR is set to '1', the value of one of the parity bit does not match the parity of the corresponding data received.
- If the flag SPDIFRX_ISR.NRZ_ERR is set to '1', a bi-mark error has been detected.
- If the flag SPDIFRX_ISR.PRE_ERR is set to '1', a preamble error has been detected.

The data rate is monitored on-the-fly and any change is reported in the flag SPDIFRX_ISR.FSE.

If the data rate change does not create an important loss of synchronization, the clock recovery logic is reloaded with the new values (see 47.6.4. Sample Frequency Measurement), thus providing a fast data recovery time. Anyway, in this case, a preamble error or a parity error can be detected.

A major data rate change can incur the loss of the clock recovery circuitry, resulting in preamble errors. It 16 consecutive preamble errors are detected, the clock recovery circuitry is automatically restarted, the flag SPDIFRX_ISR.FSE is set to "1" and as soon as circuitry is synchronized again, SPDIFRX_ISR.LOCK='1'.

The potential causes of unlocked circuitry are provided in SPDIFRX_RSR when SPDIFRX_RSR.ULOCK is set to '1'. If there is no signal (no pulse detectable on the SPDIF RX line), SPDIFRX_RSR.NOSIGNAL is set to '1'. If the SPDIF_RX line carries a signal but the format cannot be analyzed as an SPDIFRX format, SPDIFRX_RSR.BADF is set to '1'. If the SPDIFRX format is correct but the GCLK frequency provided to the SPDIFRX module does not meet the minimum frequency conditions for the sample rate frequency carried on the SPDIF_RX line, SPDIFRX_RSR.LOWF is set to '1'.

47.6.4 Sample Frequency Measurement

The SPDIFRX performs a measurement of the width of the bi-mark code pulses and reports the value in SPDIFRX_RSR.IFS. When the receiver is synchronized (SPDIFRX_RSR.ULOCK=0), the value of the field IFS corresponds to the number of GCLK periods measured for a period of 2 bits (source coding). This value can be used to determine the sampling frequency carried on the SPDIF_RX line (see 47.7.7. SPDIFRX_RSR).

47.6.5 Data Management

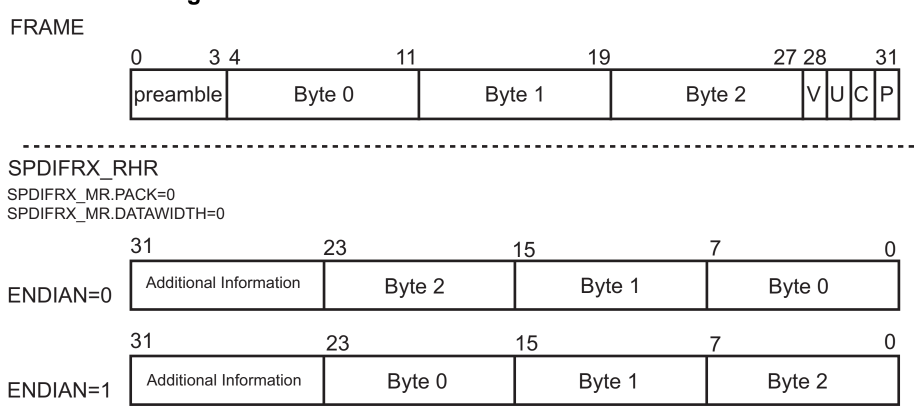
The payload data is stored for channels 1 and 2. By writing a '1' to SPDIFRX_MR.VBMODE, the receiver can be configured to automatically discard any sample with an associated validity bit set to '1'.

The endianness of the payload data can be modified during the store operation by configuring SPDIFRX_MR.ENDIAN.

Note: SPDIFRX_MR.ENDIAN applies only when SPDIFRX_MR.DATAWIDTH is set to 0 (24-bit mode).

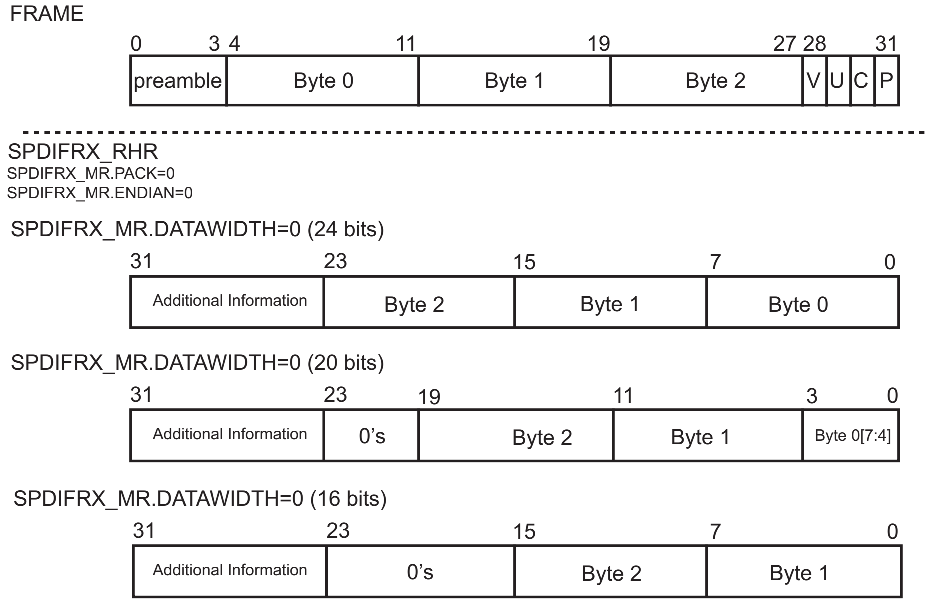
See the figure below.

Figure 47-4. Endianness Configuration Effect



The size of the payload data to be stored can be selected by configuring SPDIFRX_MR.DATAWIDTH. See the figure below.

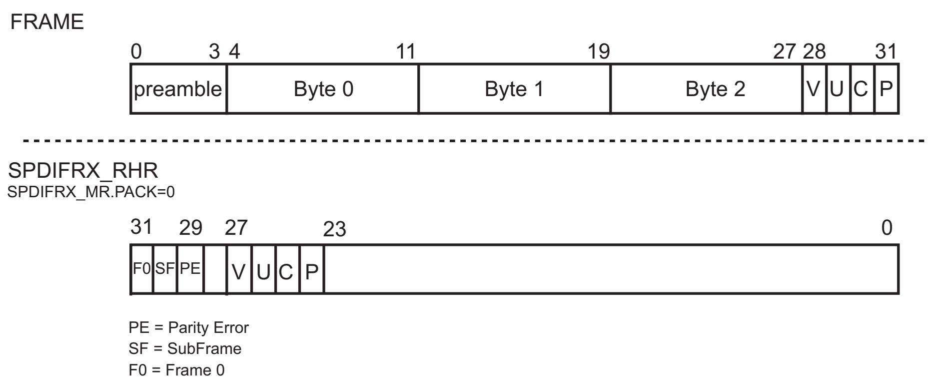
Figure 47-5. Data Size Configuration Effect



When SPDIFRX_MR.PACK is written to '1', only payload data is stored (See FIFO Organization).

When SPDIFRX_MR.PACK is written to '0', the payload data and additional information on the frame are stored in the FIFO. See the figure below.

Figure 47-6. Additional Frame Information



47.6.6 FIFO Organization

The receiver embeds one 32-element FIFO, each element having a 32-bit width. The Receiver Holding register (SPDIFRX_RHR) is the output of the FIFO. Each time a sample is written in the FIFO, the flag SPDIFRX_ISR.RXRDY is set to '1'.

The data organization in the FIFO depends on the configuration of SPDIFRX_MR.PACK and SPDIFRX_MR.DATAWIDTH.

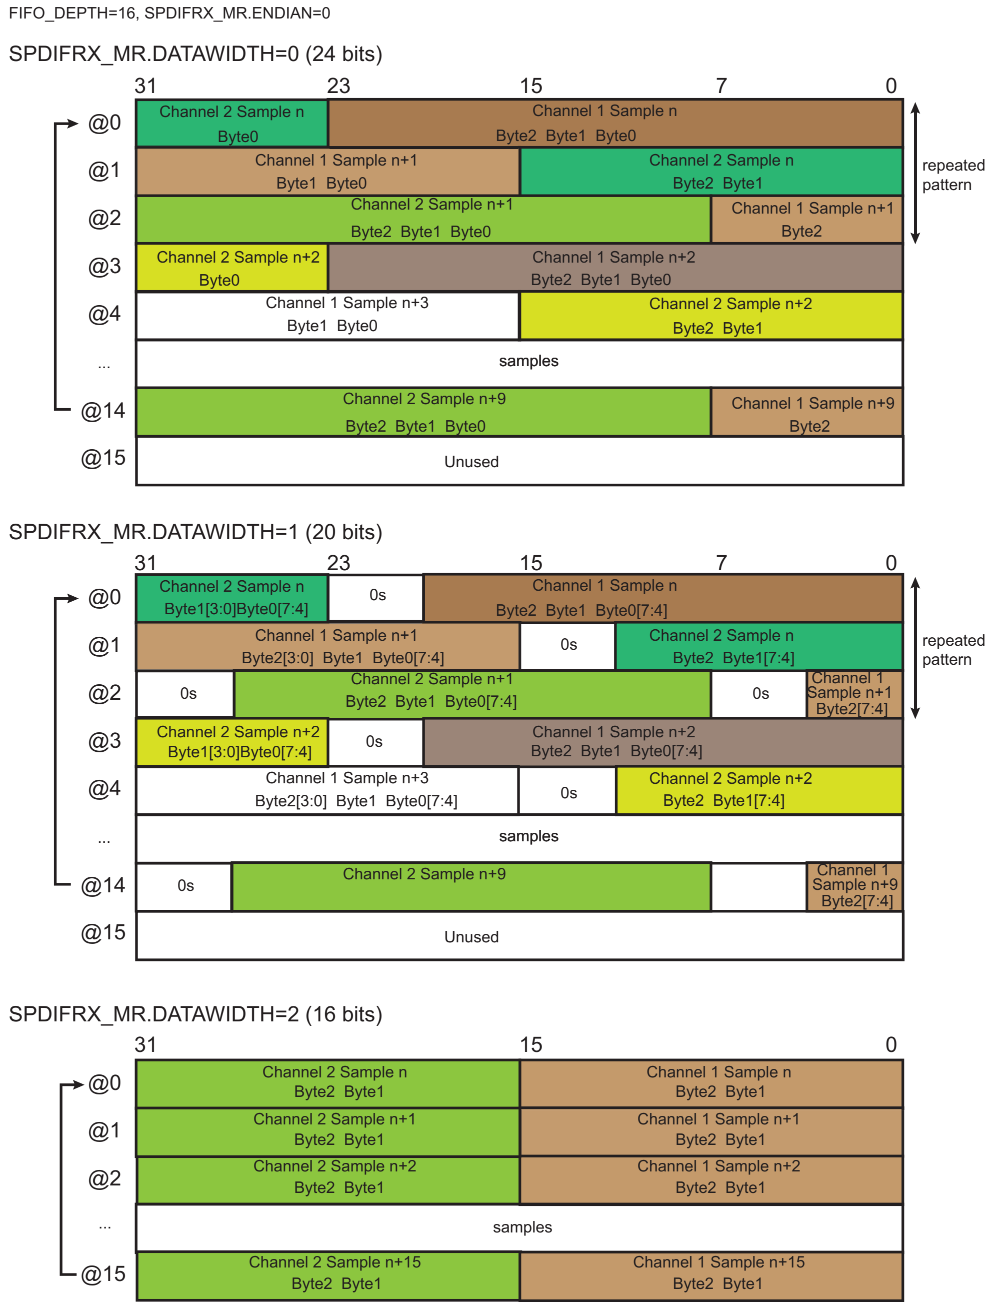
If SPDIFRX_MR.PACK=0, each FIFO element comprises one data sample and additional information (See Data Size Configuration Effect).

If SPDIFRX_MR.PACK=1, there is no additional information associated with each data sample, and the data are packed to optimize system memory amount required for processing. Thus the FIFO organization depends on the value written in the field SPDIFRX_MR.DATAWIDTH. See the figure below.

In 24-bit packed mode, the alignment is always maintained even if an overrun occurs.

When the FIFO is full, SPDIFRX_ISR.RXFULL is set to '1' and an interrupt may be triggered. If an overrun occurs, SPDIFRX_ISR.OVERRUN is set to '1' and an interrupt may also be triggered.

Figure 47-7. FIFO Organization



47.6.7 Channel Status Bit

The channel 1 status bits are stored in the Channel 1 Channel Status register (SPDIFRX_CH1SRx[x=0..5]), a 192-bit register that can be read directly from the user interface. Channel 2 status bits are stored in the Channel 2 Channel Status register (SPDIFRX_CH2SRx[x=0..5]). All 192 bits are valid when the block end status flag rises (SPDIFRX_ISR.BLOCKEND).

SPDIFRX_ISR.C1SC is set to '1' if the channel status bits 0 to 31 differ from two consecutive blocks in channel 1.

SPDIFRX_ISR.C2SC is set to '1' if the channel status bits 0 to 31 differ from two consecutive blocks in channel 2.

47.6.8 User Data Bit

The user data bits of channel 1 are stored in the Channel 1 User Data register (SPDIFRX_CH1UDx[x=0..5]), a 192-bit register that can be read directly from the user interface. The user data bits of channel 2 are stored in the Channel 2 User Data register (SPDIFRX_CH2UDx[x=0..5]). All 192 bits are valid when the block end status flag rises (SPDIFRX_ISR.BLOCKEND).

47.6.9 Write Protection Registers

To prevent any single software error from corrupting SPDIFRX behavior, certain registers in the address space can be write-protected by setting the WPEN (Write Protection Enable), WPITEN (Write Protection Interrupt Enable), and/or WPCREN (Write Protection Control Enable) bits in the SPDIF Receiver Write Protection Mode Register (SPDIFRX_WPMR).

If a write access to a write-protected register is detected, the WPVS flag in the SPDIF Receiver Write Protection Status Register (SPDIFRX_WPSR) is set and the field WPSRC indicates the register in which the write access has been attempted.

The WPVS bit is automatically cleared after reading the SPDIFRX_WPSR.

The following register can be write-protected by setting SPDIFRX_WPMR.WPEN:

- SPDIF Receiver Mode Register

The following registers can be write-protected by setting SPDIFRX_WPMR.WPITEN:

- SPDIF Receiver Interrupt Enable Register
- SPDIF Receiver Interrupt Disable Register

The following register can be write-protected by setting SPDIFRX_WPMR.WPCREN:

- SPDIF Receiver Control Register

Value	Description
0	No effect.
1	Resets the SPDIF receiver.

47.7.2 SPDIF Receiver Mode Register

Name: SPDIFRX_MR
Offset: 0x04
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the SPDIF Receiver Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
								AUTORST
Access								R/W
Reset								0

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
								SBMODE
Access								R/W
Reset								0

Bit	7	6	5	4	3	2	1	0
	PACK		DATAWIDTH[1:0]		PBMODE	ENDIAN	VBMODE	RXEN
Access	R/W		R/W	R/W	R/W	R/W	R/W	R/W
Reset	0		0	0	0	0	0	0

Bit 24 – AUTORST Consecutive Preamble Error Threshold Automatic Restart

Value	Name	Description
0	NOACTION	No action whatever the number of consecutive preamble errors found during the period where SPDIFRX_RSR.ULOCK=0.
1	UNLOCK_ON_PRE_ERR	If 16 consecutive preamble errors are detected, the clock recovery circuitry is restarted.

Bit 8 – SBMODE Start of Block Bit Mode

Value	Name	Description
0	ALWAYS_LOAD	Whatever the preamble code, the sample is loaded in FIFO.
1	DISCARD	The sample is loaded in FIFO only if a Start of Block is detected.

Bit 7 – PACK Packed Data Mode in Receive Holding Register

Value	Name	Description
0	DISABLED	Each read of SPDIFRX_RHR contains 1 sample and additional information (validity bit, parity bit, user data bit, channel status bit, byte 0 bit 1 of channel status and type of frame carrying the sample).
1	ENABLED	The 32-bit SPDIFRX_RHR contains only payload data. Depending on the value of SPDIFRX_MR.DATAWIDTH, the alignment of data differs. This mode optimizes the amount of system memory required to manage the samples.

Bits 5:4 – DATAWIDTH[1:0] Sample Data Width

Value	Name	Description
0	24BIT	The complete data field is stored in FIFO.
1	20BIT	Only the 20 MSB are stored in the FIFO.
2	16BIT	Only the 16 MSB are stored in the FIFO.
3	Reserved	Reserved

Bit 3 – PBMODE Parity Bit Mode

Value	Name	Description
0	PARCHECK	Parity check enabled on data payload.
1	NOPARCHECK	There is no parity check on data payload.

Bit 2 – ENDIAN Data Word Endian Mode

Value	Name	Description
0	LITTLE	Little-endian mode for 24-bit samples.
1	BIG	Big-endian mode for 24-bit samples.

Bit 1 – VBMODE Validity Bit Mode

Value	Name	Description
0	ALWAYS_LOAD	Whatever the validity bit value is, the sample is loaded in FIFO.
1	DISCARD_IF_VB1	The sample is loaded in FIFO only if the validity bit equals 0.

Bit 0 – RXEN SPDIF Receive Enable

Value	Name	Description
0	DISABLE	SPDIF receiver is disabled.
1	ENABLE	SPDIF receiver is enabled.

47.7.3 SPDIF Receiver Interrupt Enable Register

Name: SPDIFRX_IER
Offset: 0x10
Reset: –
Property: Write-only

This register can only be written if the WPITEN bit is cleared in the SPDIF Receiver Write Protection Mode Register.

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Enables the corresponding interrupt.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
		CP_ERR	PRE_ERR	NRZ_ERR	BLOCKST	SECE	C2SC	C1SC
Access		W	W	W	W	W	W	W
Reset		–	–	–	–	–	–	–

Bit	7	6	5	4	3	2	1	0
	RXFULL	OVERRUN	PAR_ERR	SFE	BLOCKEND	LOSS	LOCKED	RXRDY
Access	W	W	W	W	W	W	W	W
Reset	–	–	–	–	–	–	–	–

Bit 14 – CP_ERR 16 Consecutive Preamble Errors Interrupt Enable

Bit 13 – PRE_ERR Preamble Error (Code Violation) Enable

Bit 12 – NRZ_ERR NRZ Biphase Mark Error in Payload Data (Code Violation) Enable

Bit 11 – BLOCKST Start of Block Interrupt Enable

Bit 10 – SECE Security Report Interrupt Enable

Bit 9 – C2SC Bit 0 to 31 Channel 2 Status Change Interrupt Enable

Bit 8 – C1SC Bit 0 to 31 Channel 1 Status Change Interrupt Enable

Bit 7 – RXFULL Receiver FIFO Full Interrupt Enable

Bit 6 – OVERRUN FIFO Overrun, Interrupt Enable

Bit 5 – PAR_ERR Parity Bit Error Interrupt Enable

Bit 4 – SFE Sampling Frequency Change Event Interrupt Enable

Bit 3 – BLOCKEND End of Block Interrupt Enable

Bit 2 – LOSS Loss of Signal Activity While Locked Interrupt Enable

Bit 1 – LOCKED Receiver Synchronized Interrupt Enable

Bit 0 – RXRDY Receive Data Ready Interrupt Enable

47.7.4 SPDIF Receiver Interrupt Disable Register

Name: SPDIFRX_IDR
Offset: 0x14
Reset: –
Property: Write-only

This register can only be written if the WPITEN bit is cleared in the SPDIF Receiver Write Protection Mode Register.

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Disables the corresponding interrupt.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
		CP_ERR	PRE_ERR	NRZ_ERR	BLOCKST	SECE	C2SC	C1SC
Access		W	W	W	W	W	W	W
Reset		–	–	–	–	–	–	–

Bit	7	6	5	4	3	2	1	0
	RXFULL	OVERRUN	PAR_ERR	SFE	BLOCKEND	LOSS	LOCKED	RXRDY
Access	W	W	W	W	W	W	W	W
Reset	–	–	–	–	–	–	–	–

Bit 14 – CP_ERR 16 Consecutive Preamble Errors Interrupt Enable

Bit 13 – PRE_ERR Preamble Error (Code Violation) Disable

Bit 12 – NRZ_ERR NRZ Biphase Mark Error in Payload Data (Code Violation) Disable

Bit 11 – BLOCKST Start of Block Interrupt Disable

Bit 10 – SECE Security Report Interrupt Disable

Bit 9 – C2SC Bit 0 to 31 Channel 2 Status Change Interrupt Disable

Bit 8 – C1SC Bit 0 to 31 Channel 1 Status Change Interrupt Disable

Bit 7 – RXFULL Receiver FIFO Full Interrupt Disable

Bit 6 – OVERRUN FIFO Overrun, Interrupt Disable

Bit 5 – PAR_ERR Parity Bit Error Interrupt Disable

Bit 4 – SFE Sampling Frequency Change Event Interrupt Disable

Bit 3 – BLOCKEND End of Block Interrupt Disable

Bit 2 – LOSS Loss of Signal Activity While Locked Interrupt Disable

Bit 1 – LOCKED Receiver Synchronized Interrupt Disable
